Benares Obſervatory.—"We entered this building," ſays ſir Robert Barker, "and went up a ſtair-caſe to the top of a part of it, near the river Ganges, that led to a large terrace, where, to my ſurpriſe and ſatisfaction, I ſaw a number of inſtruments yet remaining, in the beſt preſervation, ſtupendouſly large, immoveable from the ſpot, and built of ſtone, ſome of them being upwards of 20 feet in height; and though they are ſaid to have been erected 200 years before, the graduations and diviſions on the ſeveral arcs appeared as well cut, and as accurately divided, as if they had been the performance of a modern artiſt. The execution in the conſtruction of theſe inſtruments exhibited a mathematical exactneſs in the fixing, bearing, and fitting of the ſeveral parts, in the neceſſary and ſufficient ſupports to the very large ſtones that compoſe them, and in joining and faſtening them into each other by means of lead and iron cramps.

"The ſituation of the two large quadrants whoſe radius is nine feet two inches, by being at right angles with a gnomon at 25 degrees elevation, are thrown into ſuch an oblique ſituation, as to render them the moſt difficult, not only to conſtruct of ſuch a magnitude, but to ſecure in the poſition for ſo long a period, and affords a ſtriking inſtance of the ability of the architect in their conſtruction; for, by the ſhadow of the gnomon thrown on the quadrants, they do not appear to have altered in the leaſt from their original poſition; and ſo true is the line of the gnomon, that, by applying the eye to a ſmall iron ring of an inch diameter at one end, the ſight is carried through three others of the ſame dimenſion to the extremity at the other end, diſtant 38 feet 8 inches, without obſtruction, ſuch is the firmneſs and art with which this inſtrument has been executed. This performance is the more extraordinary when compared with the works of the artificers of Hindooſtan at this day, who are not under the immediate direction of an European mechanic; but arts appear to have declined equally with ſcience in the eaſt.

"Lieut. Col. Arch. Campbell, at that time chief engineer in the Eaſt India company's ſervice at Bengal, a gentleman whoſe abilities do honour to his profeſſion, made a perſpective drawing of the whole apparatus that could be brought within his eye at one view; but I lament he could not repreſent ſome very large quadrants, whoſe radii were about twenty feet, being on the ſide whence he took his drawing. Their deſcription however is, that they are exact quarters of circles of different radii, the largeſt of which I judged to be twenty feet, conſtructed very exactly on the ſides of ſtone walls built perpendicular, and ſituated, I ſuppoſe, in the meridian of the place: a braſs pin is fixed at the centre or angle of the quadrant, from which the Bramin informed me they ſtretched a wire to the circumference when an obſervation was to be made; from which it occurred to me the obſerver muſt have moved his eye up or down the circumference, by means of a ladder or ſome ſuch contrivance, to raiſe and lower himſelf, till he had diſcovered the altitude

of

of any of the heavenly bodies in their paſſage over the meridian, ſo expreſſed on the arcs of theſe quadrants: theſe arcs were very exactly divided into nine large ſections; each of theſe again into ten, making ninety leſſer diviſions or degrees; and thoſe alſo into twenty, expreſſing three minutes each, of about $\frac{2}{10}$ths of an inch aſunder; ſo that it is probable, they had ſome method of dividing even theſe into more minute diviſions, at the time of obſervation.

"My time would only permit me to take down the particular dimenſions of the moſt capital inſtrument, or the greater equinoctial ſun-dial, which appears to be an inſtrument to expreſs ſolar time by the ſhadow of a gnomon on two quadrants, one ſituated to the eaſt, and the other to the weſt of it; and indeed the chief part of their inſtruments at this place appear to be conſtructed for the ſame purpoſe, except the quadrants, and a braſs inſtrument deſcribed hereafter. There is another inſtrument for the purpoſe of determining the exact hour of the day by the ſhadow of a gnomon, which ſtands perpendicular to, and in the centre of a flat circular ſtone, ſupported in an oblique ſituation by means of four upright ſtones and a croſs piece; ſo that the ſhadow of the gnomon, which is a perpendicular iron rod, is thrown on the diviſions of the circle deſcribed on the face of the flat circular ſtone. There is alſo a braſs circle, about two feet diameter, moving vertically on two pivots between two ſtone pillars, having an index or hand turning round horizontally on the centre of this circle. This inſtrument appears to be made for taking the angle of a ſtar at ſetting or riſing, or for taking the azimuth or amplitude of the ſun at riſing or ſetting.

"The uſe of another inſtrument I was at a loſs to gueſs. It conſiſts of two circular walls; the outer of which is about forty feet in diameter, and eight feet high; the wall within about half that height, and appears intended for a place to ſtand in to obſerve the diviſions on the upper circle of the outer wall, rather than for any other purpoſe; and yet both circles are divided into 360 degrees, each degree being ſubdivided into 20 ſmall diviſions, the ſame as the quadrants. There is a door-way to paſs into the inner circle, and a pillar in the centre of the ſame height with the lower circle, having a hole in it, being the centre of both circles, and ſeems to be a ſocket for an iron rod to be placed perpendicularly in it. The diviſions on theſe, as well as all the other inſtruments, will bear a nice examination with a pair of compaſſes. There is alſo a ſmaller equinoctial ſun-dial, conſtructed on the ſame principle as the large one.

"This obſervatory at Benares is ſaid to have been built by the order of the emperor Ackbar; for as this wiſe prince endeavoured to improve the arts, ſo he wiſhed alſo to recover the ſciences of Hindooſtan, and, therefore, directed that three ſuch places ſhould be erected; one at Delhi, another at Agra, and the third at Benares. Some doubts have ariſen with regard to the certainty of the ancient Bramins having a knowledge in aſtronomy, and whether the Perſians might not have introduced it into Hindooſtan when conquered by that people: but theſe doubts, I think, muſt vaniſh, when we know that the preſent Bramins pronounce, from the records and tables which have been handed to them by their forefathers, the approach of the eclipſes of the ſun and moon, and regularly as they advance give timely information to the emperor and the princes in whoſe dominions they reſided." Philoſophical Tranſactions, vol. lxvii. p. 598, or Abridgment, vol. xiv. p. 214.

The foregoing account of the Benares obſervatory has been further illuſtrated by William Hunter, eſq. in a very elaborate article in the Aſiatic Reſearches, vol. v. p. 177. in which he gives a full and particular deſcription of the other four Hindu obſervatories, and refers occaſionally to ſir Robert Barker's deſcription and plates.

Mr. Hunter's article begins with an account of the origin of thoſe obſervatories, and he gives a tranſcript of Jeyſing's preface to his aſtronomical computations in the original language, with a literal tranſlation. This preface contains an account of the aſtronomer's labours and plans, and alſo of his conference with the emperor on the ſubject of building the obſervatories. As the paper is extremely intereſting and curious, and alſo connected with our ſubject, we ſhall extract a few paſſages from it.

"Let us," ſays Jeyſing, "devote ourſelves to the altar of the king of kings; hallowed be his name in the book of the regiſter, of whoſe power the lofty orbs of heaven are only a few leaves; the ſtars, and that heavenly courſer the ſun, a ſmall piece of money in the treaſury of the empire of the moſt high."

"But ſince (Jeyſing) the well-wiſher of the works of creation, and the admiring ſpectator of the theatre of infinite wiſdom and providence, from the firſt dawning of reaſon in his mind, and during its progreſs towards maturity, was entirely devoted to the ſtudy of mathematical ſcience, and the bent of his mind was conſtantly directed to the ſolution of its moſt difficult problems; by the aid of the ſupreme artificer he obtained a thorough knowledge of its principles and rules."

* * * * * * * *

"Seeing that very important affairs, both regarding religion and the adminiſtration of empire, depend upon theſe; and that in the time of the riſing and ſetting of the planets, and the ſeaſons of eclipſes of the ſun and moon, many conſiderable diſagreements of a ſimilar nature were found; he (Jeyſing) repreſented it to his majeſty of dignity and power, the ſun of the firmament of felicity and dominion, the ſplendour of the forehead of imperial magnificence, the unrivalled pearl of the ſea of ſovereignty, the incomparably brighteſt ſtar of the heaven of empire; whoſe ſtandard is the ſun; whoſe retinue the moon; whoſe lance is Mars, and his pen like Mercury, with attendants like Venus; whoſe threſhold is the ſky; whoſe ſignet is Jupiter; whoſe centinel Saturn; the emperor deſcended from a long race of kings; an Alexander in dignity; the ſhadow of God; the victorious king, Mahommed Shah, may he ever be triumphant in battle."

"His majeſty was pleaſed to reply, 'Since you, who are learned in the myſteries of ſcience, have a perfect knowledge of this matter; having aſſembled the aſtronomers and geometricians of the faith of Iſlam and the Bramins and Pandits, and the aſtronomers of Europe, and having prepared all the apparatus of an obſervatory, do you ſo labour for the aſcertaining of the point in queſtion, that the diſagreement between the calculated times of thoſe phenomena, and the times in which they are obſerved to happen, may be rectified.'

* * * * * * * *

"Although this was a mighty taſk, which, during a long period of time, none of the powerful rajahs had proſecuted; nor, among the tribes of Iſlam, ſince the time of the martyr prince, whoſe ſins are forgiven, Mirza Uluga Beg to the preſent, which comprehends a period of more than 300 years, had any one of the kings, poſſeſſed of power and dignity, turned his attention to this object; yet, to accompliſh the exalted command which he had received, he (Jeyſing) bound the girdle of reſolution about the loins of his ſoul, and conſtructed here (at Delhi) ſeveral of the inſtruments

ſtruments of an obſervatory, ſuch as had been formerly erected at Samarcand, agreeably to the Muſſulman books.

* * * * * * * * *

"Thus an accurate method of conſtructing an obſervatory was eſtabliſhed; and the difference which had exiſted between the computed and obſerved places of the fixed ſtars and planets, by means of obſerving their mean motions and aberrations with ſuch inſtruments, was removed. And in order to confirm the truth of theſe obſervations, he conſtructed inſtruments of the ſame kind in Suvai Jeypour, and Matra, and Benares, and Oujein. When he compared theſe obſervatories, after allowing for the difference of longitude between the places where they ſtood, the obſervations and calculations agreed. Hence he determined to erect ſimilar obſervatories in other large cities, that ſo every perſon who is devoted to theſe ſtudies, whenever he wiſhes to aſcertain the place of a ſtar, or the relative ſituation of one ſtar to another, might by theſe inſtruments obſerve the phenomena."

From the foregoing extract of the Aſiatic Reſearches it appears, that although ſir Robert Barker's deſcription of Benares obſervatory is allowed to be very correct, yet he was not well informed as to the ſituation or number of the other obſervatories, or the names of their founders.

At Pekin, in China, there was an imperial obſervatory built in the thirteenth century, on the city walls; and in 1669, father Verbieſt, a miſſionary Jeſuit, having been made preſident of the tribunal of mathematics there, and chief obſerver, obtained permiſſion from the emperor Cam-hi to furniſh it with new inſtruments, a catalogue of which may be ſeen in Duhalde's Deſcription of China.

Other obſervatories were built in China ſubſequently by the French miſſionaries, and by the Portugueſe Jeſuits, who diſtinguiſhed themſelves very much by their improvements in aſtronomy, notwithſtanding the duties of a very different nature in which they were employed, and to which they are ſuppoſed likewiſe to have paid due attention. The inſtruments of the Pekin obſervatory are deſcribed as exceedingly large, but the diviſions leſs accurate, and the contrivance in ſome reſpects leſs commodious than the inſtruments made at that period in Europe. The chief were, a ſextant eight feet radius, a quadrant ſix feet radius, an azimuthal horizon, alſo a celeſtial globe, an armillary zodiacal ſphere, each ſix Paris feet diameter, (the French toiſe which equals 6 feet $4\frac{3}{4}$ inches nearly Engliſh meaſure).

It is ſaid that Copernicus, in 1540, was the firſt European who ſet an inſtrument in the meridian, but it is ſtated by Weidler, Bailly, and Coſtard, that the firſt regular obſervatory in Europe was erected at Caſſel in 1561, by William I., landgrave of Heſſe, who furniſhed it with the beſt inſtruments the age could afford. He is ſaid to have made very accurate obſervations in concert with his friend and correſpondent, Tycho Brahe, who was at the above period riſing into great fame, and the high expectations formed of him were fully anſwered.

The next obſervatory in Europe that deſerves particular notice, was that of Tycho Brahe himſelf, which owed its origin, according to Bailly, to a very extraordinary cauſe. This was the appearance of a new ſtar of the firſt magnitude, in the conſtellation of Caſſiopeia. It was ſeen by different aſtronomers about the 10th of November, 1572, and as ſome of them had been before in the habit of obſerving that conſtellation, the appearance was ſuppoſed to be inſtantaneous, which added to the unuſual aſtoniſhment and conſternation that univerſally prevailed on the occaſion. It was brighter than Jupiter or Venus when neareſt to the earth, and was viſible to the naked eye at noon day. After a ſhort time it gradually declined, and in ſixteen months totally diſappeared. Many curious and alarming predictions were the conſequence, and Tycho Brahe, who obſerved it from the beginning, was ſo impreſſed with the phenomenon, that he formed a reſolution of making a new and accurate catalogue of all the ſtars, as there had been nothing of the kind regularly performed ſince the days of Hipparchus, who, it is remarkable, had been ſtimulated to the undertaking by a ſimilar cauſe, that is, by the ſudden appearance and diſappearance of a new ſtar. Tycho Brahe communicated his deſign to ſeveral eminent men, who encouraged the plan. He firſt propoſed to ſettle at Baſle, which afforded at once a pure atmoſphere, and a ready communication with the learned men of Germany, Italy, and France; but the landgrave of Heſſe wrote to Frederic II., king of Denmark, intreating him to encourage the aſtronomer to remain in his own country. The king, fully ſenſible of the loſs with which he was threatened, offered him the ſmall but fertile iſland called Huen, or Hwen, in the Sound, as a deſirable ſituation for an obſervatory. His majeſty conferred on him alſo other princely grants and immunities, which were accepted. He beſides undertook to defray the expence of building and furniſhing the obſervatory there, without any limitation of expence, a munificence which has immortalized his name. The firſt ſtone of the obſervatory was laid the 8th of Auguſt, 1576, and the place was called Uranibourg, or the Heavenly city. It was a building of 60 feet ſquare, and 70 feet high, with four towers, all contrived for aſtronomical purpoſes. It was furniſhed with a noble collection of inſtruments, many of which had been invented and brought to perfection by the aſtronomer himſelf. He had numerous aſſiſtants, whom he ſupported and inſtructed. (For his aſtronomical obſervations there, ſee the life of Brahe, Tycho.) Among his inſtruments was a celeſtial globe, of ſix feet diameter, which is ſaid to have coſt above 1000*l*. It was after his death carried to Prague, next to Neis, and laſtly to Copenhagen, where it was burnt in the great conflagration which happened there in 1728. Many of the inſtruments of this great aſtronomer were long preſerved, but have been gradually loſt, and his favourite city Uranibourg, which, in his time, was viſited by kings and princes, who paid him the higheſt honours, has been long a heap of ruins, but is ſtill viſited by the learned, and regarded with pious veneration. It ſhould have been mentioned that his celebrated ſextant has been conſecrated in the heavens as a conſtellation, under the breaſt of the lion. On large globes and atlaſes it is marked *Sextans Uraniæ*, but on common ones only *Sextans*.

We ſhall now proceed to give ſome deſcription of obſervatories of a more modern date, beginning with thoſe of France.

French Obſervatories.—The Imperial obſervatory (formerly called the "Royal Obſervatory," and during the time of the republic the "Obſervatory") was built in 1667, and is ſtated by La Lande to be "the moſt ſplendid monument ever dedicated to aſtronomy." It is 160 Engliſh feet in front, and 120 in breadth, and 90 feet high. Its vaults are 90 feet deep, ſo that it is 180 feet from top to bottom. For a particular deſcription of the architecture, ſee Blondel; and for the arrangement and diſpoſition of the inſtruments, ſee Bernouilli's Lettres Aſtronomiques, alſo La Lande's Aſtronomie, and Monnier's Hiſtoire Celeſte.

Beſides the above building, new rooms have been conſtructed, cloſe by the ſide of the obſervatory, where a large tranſit inſtrument and circle, by Ramſden, have been ſet up. In 1788 new vaults were made, and alſo a ſmall obſervatory erected at the top of the building, which commands an extenſive view of the horizon, and the king (Louis XVI.) eſtabliſhed

eſtabliſhed three obſervers here, that the courſe of obſervations might as little as poſſible be interrupted.

The following account of other obſervatories at Paris, given by La Lande in 1792, is worthy of being inſerted here, as intereſting in the hiſtory of practical aſtronomy.

"The aſtronomers of the academy had beſides ſeveral private obſervatories erected in different parts of Paris, as the royal obſervatory was not ſufficient for all. That of M. le Monnier has been, from the year 1742, in the garden of the Capuchins. That of the Marine, which Joſeph de l'Iſle uſed in 1748 at the Hotel de Clugny, where I laboured during two years, is at preſent occupied by M. Meſſier. That of La Caille ſtill exiſts in the Mazarin college. I, as well as M. d'Agelet, have made ſeveral obſervations there ſince his death. That of the palace of Luxembourg is above the Port Royal. Joſeph de Liſle obſerved there, and I likewiſe occupied it for ſome time. That of M. Pingré at the abbey of St. Génévieve was built in 1756. There is one of M. Cagnoli's, rue de Richlieu, which this able aſtronomer built at his own expence in 1785, when he ſtill reſided at Paris.

"The obſervatory of the military ſchool, built for M. Jeaurat in 1768, was occupied afterwards by M. d'Agelet. The late M. Bergeret, receiver-general of finances, conſtructed in 1774, at my requeſt, a large mural quadrant of eight Engliſh feet radius, the laſt and the beſt inſtrument made by the celebrated Bird, the loſs of whoſe talents we ſtill regret. This inſtrument was obtained by the military academy, as well as an excellent tranſit inſtrument, and a parallactic teleſcope. M. d'Agelet made a great number of obſervations there from 1778 to 1785, when he left it to make a voyage round the world with La Perouſe. In 1788, the changes made in the military ſchool occaſioned the demolition of this obſervatory; but it has been rebuilt, by my deſire and care, a little more to the weſt, with all neceſſary attention and expence, ſo that it is the moſt complete obſervatory we have at Paris. Having received the direction of it, I began, in 1789, to make the following obſervations. M. le François La Lande, my relation and pupil, who is a very good aſtronomer, has alſo made a prodigious number of obſervations, and we obſerved, in 1791, more than ten thouſand northern ſtars, with excellent inſtruments. This work was very much wanted, and I conſider it as one of the moſt important and difficult things that could be undertaken for aſtronomy.

"An obſervatory was built in 1775, at the Royal College, for the uſe of the profeſſor of aſtronomy of this celebrated ſchool. M. Geoffroy d'Aſſy built, in 1788, an obſervatory at his houſe, rue de Paradis, and it will become one of the moſt uſeful by the zeal and intelligence of M. de Lambre, who uſes it."

Such was the ſtate of obſervatories at Paris in 1792. At preſent (1813), De Lambre is the chief of the imperial univerſity. Meſſier and Biot ſucceeded him at the Royal College, now the College de France. Burckhardt is aſtronomer at the military ſchool; Lefrançois la Lande reſides at the Place de Cambray; and Bouvard ſuperintends the imperial obſervatory, aſſiſted by Aragon.

It is worthy of notice here, that the famous mural quadrant, with which La Lande and his relation determined the poſition of a great number of ſtars, as above-mentioned, has been conſecrated in the heavens as a conſtellation, and is placed between Hercules, the Serpent, and Bootes. It is marked *Quadrans muralis*, and contains forty ſtars.

The following were the other obſervatories eſtabliſhed in different parts of France, as ſtated by La Lande.

The MARSEILLES obſervatory, which has been rendered famous by the obſervations of M. de Sylvabelle.

At TOULOUSE, the obſervatory of M. Darquier has been made ſacred by the zeal and abilities of this learned man. Obſervatories have alſo been built in the ſame city by M. Garipuy and M. Bonrepos. Here aſtronomy has been more ſucceſsfully cultivated than in any other provincial city in France. The principal obſervatory is at preſent (1813) under the ſuperintendance of M. Vidal.

At LYONS, the College obſervatory, which was built by father St. Bonnet, is a very fine edifice, on an elevated ſituation.

At DIJON, M. Necker, about the year 1780, converted the tower of the king's lodge to an obſervatory, and the abbé Bertrand has made very accurate obſervations here.

At MONTPELLIER there has long been an obſervatory erected on one of the towers of the city. M. Ratte and M. Poitevin have diſtinguiſhed themſelves here as able aſtronomers.

At BEZIÈRS, the Biſhop's tower was converted to an obſervatory, where ſome intereſting obſervations have been made by M. Bouillet, particularly on Saturn's ring.

At AVIGNON, an obſervatory was built by father Bonfa ſo early as 1683, and it has been ſince occupied by a ſucceſſion of learned eccleſiaſtics, who have diſtinguiſhed themſelves in practical aſtronomy.

At STRASBURG, Brackenhoffer, profeſſor of mathematics, had an obſervatory over the gates of the city, and he has been ſucceeded by Herzenſchneider in 1790.

At BOURDEAUX is an obſervatory 75 feet high, and 20 feet ſquare. It is ſituated in the fineſt part of Tournay, in latitude 45°, which is the middle of the temperate zone that we inhabit. Here M. Turgot procured a complete ſet of obſervations to be made on the length of a pendulum vibrating ſeconds; upon which father Boſcovich has made an intereſting memoir.

At BREST a ſmall obſervatory was built for the naval academy, and plans have been ſet on foot for erecting a more conſiderable edifice.

At ROUEN there is an obſervatory belonging to M. Bouin, in which he has made many good obſervations.

At MONTAUBAN the duc de la Chappelle founded an obſervatory, where he himſelf has made many accurate and intereſting obſervations, particularly of the tranſit of Venus over the ſun in 1769.

German Obſervatories.—In Germany a great number of obſervatories have been eſtabliſhed, and that country has produced alſo ſeveral very able aſtronomers.

AT BERLIN, Frederic I., king of Pruſſia, founded an obſervatory in 1711, under the direction of Leibnitz, who was preſident of the Academy of Sciences there. It is a large ſquare tower, very ſteady. Here Griſchow and Kies made various obſervations: and La Lande alſo obſerved here about the year 1752, where, he ſays, he raiſed enormous pillars, to which he attached the mural quadrants, north and ſouth. (Memoires de l'Academie, 1751 and 1752.) King Frederic II. added a very fine building to it, where the Academy of Sciences of Pruſſia has held its aſſemblies. M. Bode has been many years the aſtronomer royal here, and has diſtinguiſhed himſelf both as an accurate obſerver, and as the publiſher of the moſt complete celeſtial atlas extant, entitled "Uranographia," which is accompanied with a well arranged catalogue of the ſtars, and an intereſting hiſtory of the conſtellations.

At VIENNA, the empreſs Maria Thereſa built an obſervatory in the year 1755 for the univerſity, and furniſhed it with many ſuperb inſtruments. There is alſo one belonging to the academical college, which was built and endowed by the Jeſuits in 1735, and it is likewiſe furniſhed with very fine inſtruments, chiefly made by Engliſh artiſts,

tifts, and a ſucceſſion of very learned men have obſerved there. The reputation of the univerſity obſervatory was maintained for many years by the abbé Maximilian Hell, who conducted the Vienna Ephemeris, and this work is now continued by M. Treiſneckir, his ſucceſſor.

At GOTTINGEN there is an obſervatory memorable by the labours of Tobias Mayer, and by thoſe more recently of Harding, who diſcovered the planet Juno in 1804.

At NUREMBERG an obſervatory was built ſo early as the year 1678, and another in 1692. M. Zimmert and M. Wuzzelbau have diſtinguiſhed themſelves here both as able authors and accurate obſervers.

At CASSEL an obſervatory was built, in 1714, by Charles I., landgrave of Heſſe, heir to the territories and taſte of the celebrated William, the early friend and fellow labourer of Tycho Brahe.

In 1740 an obſervatory was built at Grieſſen; and in 1768 at Ourtſbourg, in Franconia. In 1788 there was one built at Leipſic, on an old tower of great firmneſs. Obſervatories have been likewiſe erected and ſupported with great credit at Manheim, Cremſmunſter, Lambach, Polling, Prague, and Gratz.

At BREMEN there is an obſervatory belonging to Dr. Olbers, an eminent phyſician, who has rendered his name immortal by the diſcovery of the two new planets, Pallas and Veſta. See PLANET.

At LILIENTHAL, near Bremen, M. Schroeter, governor of the diſtrict, erected an obſervatory about the year 1786, and furniſhed it with excellent inſtruments. He is highly celebrated as an accurate and intereſting obſerver, particularly of the ſurfaces and rotations of the planets and the moon. He approaches nearer than any other aſtronomer to Dr. Herſchel in teleſcopic diſcoveries.

At SEEBERG, near Gotha, a conſiderable obſervatory was built, in the year 1788, by the duke of Saxe Gotha, and he appointed M. Zach, now baron Zach, the ſuperintendant, who has highly diſtinguiſhed himſelf as a profound and accurate aſtronomer. In 1798 he was viſited by La Lande, when, according to Voiron, (Hiſtoire de l'Aſtronomie, p. 369.) all the great aſtronomers of Germany met at Gotha to ſee the patriarch of aſtronomy, and to pay him their homage. This obſervatory is reckoned one of the moſt beautiful and complete in Europe; it is ſituated on a fine elevation, about a league from the town. There is here a large tranſit, with two murals of eight feet radius, and a circle of eight feet diameter, all by Ramſden and his ſucceſſor Berge.

At BRUNSWICK there is an obſervatory belonging to Dr. Gauſs, well known by his determinations of the orbits of the new planets, and other important labours.

In HUNGARY there are obſervatories at Buda, Tyrnau, and Erlau. Similar eſtabliſhments are alſo at Greiffswalde in Pomerania, and at Mittau in Courland.

In POLAND there is an obſervatory at Cracow, and another at Wilna: the latter was built and richly endowed by the counteſs Puzynina, a lady of fine genius as well as liberality. It was finiſhed in 1753, and the inſtruments with which it is furniſhed were of great variety and value. In 1765 the king of Poland, by letters patent, gave it the title of Royal obſervatory, and appointed the learned jeſuit Poezobut aſtronomer royal, who, in 1788, added another obſervatory, which he furniſhed with new inſtruments, chiefly made by Ramſden.

In SWEDEN obſervatories have been built at Stockholm and Upſal; that at Stockholm was founded in 1746, by the Academy of Sciences. In 1753, Wargentin was appointed aſtronomer to it, and in 1783 he was ſucceeded by Nicander. This obſervatory is ſituated on a hill north of the town, and contains a good collection of inſtruments, all made by Engliſh artiſts.

The obſervatory at Upſal was built and endowed in 1739 by the king of Sweden: it was firſt ſuperintended by the celebrated Celſius, who has been followed by a ſucceſſion of able aſtronomers, particularly Hooker and Wargentin. The latter is well known as the author of the tables of Jupiter's ſatellites.

At DANTZIC there was an old obſervatory, celebrated as having been uſed by Hevelius, who has given a full deſcription of it in his work, entitled "Machina Cæleſtis." A new obſervatory was alſo built in that city in the year 1778, and is at preſent ſuperintended by Dr. Wolff.

At COPENHAGEN the famous aſtronomical tower was finiſhed in 1656. It was built by king Chriſtian IV. at the recommendation of Longomontanus, and has been for many years under the management of Mr. Bugge, who is celebrated as a very able aſtronomer. In his collection of obſervatories, he ſtates that the kings of Denmark had eſtabliſhed obſervatories in Norway, Iceland, and Greenland.

In HOLLAND attention was paid to practical aſtronomy while it was a maritime ſtate, but the ſcience has of late been much neglected. In 1690 an obſervatory was erected upon the college of the univerſity, and at Utrecht an ancient tower was, in 1726, converted into an obſervatory. Here the celebrated Van Muſſchenbroek obſerved for many years with great accuracy, and he was ſucceeded by M. Hennert.

In SPAIN obſervatories have been built at Cadiz, Madrid, Seville, and Carthagena. The obſervations made at Cadiz (at the Marine academy) by Miguel and Varilla, have been publiſhed in two volumes, which alſo contain a catalogue of the inſtruments of the obſervatory, chiefly conſtructed by French artiſts; and hence the obſervatories of Spain differ very little from thoſe of France. Of late years, however, Engliſh inſtruments have been introduced there.

At LISBON, in 1728, king John V. had an obſervatory erected at his palace, which was well furniſhed, and accurate obſervations have been made there by the Jeſuits, who alſo erected an obſervatory at their own college of St. Anthony, where father Carbon, in 1726, made good obſervations on the ſatellites of Jupiter. See Phil. Tranſ. vol. xxxv. p. 408.

In 1787, a Royal obſervatory was conſtructed at the Chateau de St. George, in Liſbon, which was ſuperintended by M. Cuſtodio Gomez. There is alſo one at COIMBRA, which contains a fine equatorial by Troughton.

At PETERSBURG an obſervatory was built, in 1725, by the czar Peter, who ſhewed great zeal for ſcience in general, and particularly for aſtronomy. When he was in England, ſome years before that period, he viſited the Royal Obſervatory at Greenwich, where he examined both the building and the inſtruments with very great attention. The obſervatory which he afterwards built is one of the moſt magnificent in Europe. It is 130 feet high, with three ſtories, all fit for aſtronomical purpoſes. M. de l'Iſle has made, according to La Lande, a great number of excellent obſervations here, which are preſerved in manuſcript in the Marine depot.

At Moscow an obſervatory was built a few years ago, and furniſhed with ſome excellent Engliſh inſtruments, chiefly by Cary; but it is probable that they have been deſtroyed in the late conflagration of that city.

In ITALY, practical aſtronomy has been cultivated with much aſſiduity and ſucceſs during the laſt century, chiefly by eccleſiaſtics, and particularly by the Jeſuits.

At ROME, cardinal Zelada conſtructed, at his own expenſe, on the ſouthern part of the Roman college, a very fine obſervatory, with the large ſector of father Boſcovich, and other inſtruments by Ramſden and Dollond; the abbé Calandrelli obſerved here with great attention and accuracy

for many years. Other buildings of a ſimilar deſcription have been erected in different parts of Rome.

At Bologna a magnificent obſervatory was built in 1714, in the palace of the Inſtitute, by the munificence of the celebrated count Marſigli; and pope Benedict XIV. gave afterwards a large ſum of money towards the purchaſe of inſtruments. Here a ſucceſſion of able aſtronomers have obſerved, among whom may be mentioned Manfredi, Zanotti, Canterzani, &c.

At Pisa the obſervatory is in the form of a tower. It was built in 1730, at the expence of the univerſity, and ſupplied with ſuperb apparatus made by Siſſon, Short, Graham, &c. Perelli obſerved here for many years, and had for a ſucceſſor M. Slope, who publiſhed an excellent collection of obſervations in 1789.

At Milan there is an obſervatory, which is reckoned one of the moſt uſeful in Italy. It was built in 1765, at the coſt of the college of the Jeſuits, chiefly through the zeal of father Pallavicini, and under the direction of father Boſcovich, who alſo contributed liberally to the expenſe. The inſtruments have been made with great care by the principal French and Engliſh artiſts. Among the obſervers may be alſo mentioned Reggio, Oriani, and Ceſaris.

At Florence, father Ximenes erected an obſervatory at the college of Jeſuits, which contains a quadrant by Toſcanelli, larger than any other known, with which he made obſervations to prove the ſecular diminution of the obliquity of the ecliptic. At his death he bequeathed the whole to the college. In 1772 the grand duke Leopold built an obſervatory, which M. Fontana ſuperintended, and in 1786 ſeveral fine inſtruments by Ramſden were added to it.

At Turin father Beccaria erected a ſmall obſervatory; but in 1790 a large one was built at a very conſiderable expenſe, by the king of Sardinia, at the Royal College of Nobles, and the direction of it given to the abbé Caluſo.

At Venice an obſervatory was conſtructed by father Panigai, and a ſmall one near the town by M. Miotti. One was alſo built at Parma by father Belgrado, and another at Brescia by father Cavalli.

At Verona, Cagnoli, eminent both as a mathematician and aſtronomer, erected an obſervatory at his own expenſe in 1787, and placed in it the beſt inſtruments, with which he has made very accurate and important obſervations, particularly on the preceſſion of the equinoxes, and on the places of 473 northern ſtars, and 28 ſouthern, of which he has made a catalogue. In theſe determinations he has been perhaps more attentive than any other aſtronomer to the minute changes of refraction, and to the aberration of light.

At Padua there is an obſervatory, which, in 1778, was furniſhed with inſtruments chiefly made by Ramſden. It has been many years under the direction of M. Toaldo, who has publiſhed ſeveral uſeful works, eſpecially a treatiſe on Meteorology, which gained him the prize at the academy of Montpellier.

The obſervatory at Padua was originally the tower of the cruel tyrant Egellin, in the 13th century; in the dungeons of which he confined ſuch priſoners of war as fell into his hands during the civil commotions of that period. In 1769 it was converted into an obſervatory, and this happy change gave riſe to the following diſtich of father Boſcovich; who united the rare talents of poet and mathematician.

"Quæ quondam infernas turris ducebat ad umbras,
Nunc Venetum auſpiciis pandit ad aſtra viam."

which may be thus tranſlated:

"This tow'r, which led to Pluto's realms below,
To heaven's bright regions now the way doth ſhew."

In ſome of the iſlands of the Mediterranean obſervatories have alſo been eſtabliſhed. We ſhall, however, notice only thoſe of Malta and Sicily.

In 1783, the grand maſter Emmanuel de Rohan, an amateur and enlightened protector of ſcience, invited to Malta chevalier d'Angos, a ſkilful aſtronomer, who converted a tower of the palace into an obſervatory, which was furniſhed with the fineſt inſtruments that could be procured. In a few years he made a great number of valuable obſervations, which he intended to publiſh, but in March 1789, the obſervatory having caught fire, the inſtruments were broken, and the papers burnt, a ſerious loſs to aſtronomy, particularly as this was the moſt ſouthern obſervatory of Europe, in latitude 36°.

At Palermo an obſervatory has been conſtructed in the palace of the viceroy, under the direction of father Piazzi, who went to Paris in 1787 to ſtudy aſtronomy, and who afterwards viſited England, in order to conſult the principal artiſts on the conſtruction of inſtruments. In 1789 he returned to Palermo, and added to the apparatus a fine tranſit inſtrument, and a complete circle, made by Ramſden. His firſt labours were directed to the formation of a correct catalogue of ſtars, and, as a foundation, he choſe Wollaſton's catalogue, and particularly, as his chief points of reference, Dr. Maſkelyne's 36 ſtars. The poſitions of ſome of the larger ſtars he verified by nearly a hundred obſervations, and in the proſecution of this taſk, in 1801, he diſcovered a new planet, which he named Ceres, in honour of Sicily, as that iſland was, on account of its fertility, anciently conſecrated to the goddeſs Ceres. This diſcovery was the more important, as it excited the curioſity and reſearch of other aſtronomers, by which three more planets have been ſince diſcovered.

Engliſh Obſervatories.—The *Greenwich obſervatory*, or the Royal Obſervatory of England, was built and endowed by king Charles II., who, to uſe the words of Bailly, "well knew how eſſential aſtronomy was to a maritime and commercial people like the Engliſh, who aſpired to the empire of the ſeas." This building was erected on the ſcite of the ancient moated tower of duke Humphrey, uncle to Henry VI., and the firſt ſtone of it was laid Aug. 10, 1675, by Mr. Flamſteed, who had been appointed aſtronomer royal. It is ſituated on the higheſt eminence of Greenwich park, about 160 feet above low water mark. The ſoil here is particularly favourable for ſuch an inſtitution, being of a flinty gravel, through which the rain ſoon paſſes, and thus the atmoſphere is generally dry, which contributes to the preſervation of the inſtruments, as well as to the uniformity of refraction.

This eſtabliſhment comprehends two principal buildings, one of which is the obſervatory, and the other the dwelling-houſe of the aſtronomer royal. The obſervatory is an oblong edifice, running eaſt and weſt, and containing four rooms, or apartments on the ground-floor. The firſt, or moſt eaſterly room, has been lately erected for the reception and fitting up of a very fine tranſit circle, by Troughton, and a clock of great value by Hardy.

The next apartment is the tranſit room. It has a double ſloping roof, with ſliding ſhutters, which are opened both north and ſouth, with great eaſe, by pulleys. The tranſit inſtrument, which is eight feet long, and the axis three feet, is ſuſpended on two ſtone pillars. This inſtrument is famous as having been uſed by Halley, Bradley, and Maſkelyne. It was originally made by Bird, and has been ſucceſſively improved by Dollond and Troughton. The aſtronomical or tranſit clock, which is attached to a ſtone pillar, was made by Graham, and has been rendered very accurate by Earnſhaw.

The third apartment is the aſſiſtant obſerver's library and place for calculation; and the weſtern apartment of the building is the quadrant room. Here is erected a ſtone

ſtone pier, running north and ſouth, to which are attached two mural quadrants, each of eight feet radius. That on the eaſtern face, which obſerves the ſouthern meridian, was made by Bird, and the other, which obſerves the northern, by Graham. Suſpended to the weſtern wall is the famous zenith ſector, with which Bradley made the obſervations at Kew and Wanſtead, that led to the diſcoveries of the aberration of light, and the nutation of the earth's axis.

South of the quadrant room is a ſmall wooden building for making occaſional obſervations in any direction, where only the uſe of a teleſcope, and an accurate knowledge of the time, are required. It is furniſhed with ſliding ſhutters on the roof and ſides, to view any point of the hemiſphere, from the prime vertical down to the ſouthern horizon. It contains ſome excellent teleſcopes, particularly a forty-inch achromatic, with a triple object-glaſs, and a five-feet achromatic, both by Dollond; with a ſix-feet reflector, by Dr. Herſchel.

To the north of the obſervatory and eaſt of the houſe are two ſmall buildings, covered with hemiſpherical ſliding domes, in each of which is an equatorial ſector, by Siſſon, and a clock, by Arnold. Theſe are chiefly uſed for obſerving comets.

With reſpect to the dwelling-houſe, the lower apartments are occupied by the aſtronomer royal, and over them is a large octagonal room, which contains a great variety of aſtronomical inſtruments, with a library, conſiſting chiefly of ſcientific and ſcarce works. On the top of the houſe is an excellent camera obſcura, which could not be better placed for the exhibition of intereſting objects.

It is not unworthy of notice, that early in Flamſteed's time there was a well ſunk in the ſouth-eaſt corner of what is now the garden, behind the obſervatory, for the purpoſe of ſeeing the ſtars in the day-time, and obſerving the earth's annual parallax. It was a hundred feet deep, with ſtone ſtairs down to the bottom: but it has been long arched over, as the improvements in the teleſcope have rendered it unneceſſary for aſtronomical purpoſes.

The obſervations made at the Royal Obſervatory are univerſally allowed to poſſeſs an unrivalled degree of accuracy. M. Delambre, in a paper compoſed by him, on the life and labours of Dr. Maſkelyne, and read before the National Inſtitute, Jan. 4, 1813, makes the following remark. "He (Dr. Maſkelyne) has given a catalogue of ſtars, not numerous, but ſo accurate, as to have ſerved, almoſt ſolely for the laſt 30 years, as the foundation of all aſtronomical reſearches. In ſhort, it may be ſaid of the four volumes of Obſervations which he has publiſhed, that if, by a great revolution, the ſciences ſhould be loſt, and that this collection only were ſaved, there would be found in it ſufficient materials to conſtruct almoſt an entire edifice of modern aſtronomy; which cannot be ſaid of any other collection."

For ſimilar atteſtations made by foreign aſtronomers of the utility and importance, as well as ſuperior accuracy, of the Greenwich obſervations, ſee our life of Dr. Maſkelyne.

The following are the names of the aſtronomers who have officiated here in ſucceſſion, with the times of their ſervices reſpectively: Flamſteed, 43 years; Halley, 23 years; Bradley, 20 years; Bliſs, 2 years; and Maſkelyne, 46 years. (For a particular account of their labours, ſee their lives, as well as the various aſtronomical articles of this work.) Dr. Maſkelyne has been ſucceeded by John Pond, eſq. F. R. S. who was appointed aſtronomer royal in February 1812.

In giving a deſcription of the Royal obſervatory, it may be deemed an omiſſion not to notice the peculiar beauty of the ſituation. The building itſelf is no way remarkable, but it commands one of the fineſt proſpects, perhaps, in the world, both for richneſs and variety; and the intereſt of the view which it commands of public proſperity is greatly enhanced by conſidering that it is chiefly the reſult of nautical ſcience; and that thoſe numberleſs veſſels which cover the Thames with the wealth of nations, and which traverſe the remoteſt ſeas, owe their ſcience and their ſafety, in a great meaſure, to the Greenwich obſervatory.

Dr. Herſchel's Obſervatory at Slough, near Windſor, though not a fixed one, will ever claim a diſtinguiſhed place in the hiſtory of aſtronomical inſtitutions. It differs from all other obſervatories in plan and apparatus; and it exceeds all others in the number of its diſcoveries. For this important eſtabliſhment the world is indebted to the munificence of his preſent majeſty, George III., who has liberally patronized Dr. Herſchel, and who on other occaſions has ſhewn himſelf a zealous and enlightened promoter of aſtronomy.

In deſcribing this obſervatory, it ſhould be premiſed, that Dr. Herſchel's labours derive a peculiar character and intereſt from the circumſtance, that his diſcoveries are the reſult of his own inventions. For to his profound knowledge of aſtronomy he unites that of optics, both in theory and practice, by which he has been enabled to caſt and poliſh mirrors for reflecting teleſcopes, greatly ſuperior to any others, not only in magnifying power, but in collecting, or, as it were, preſerving light, by which viſion is wonderfully extended, and which he very expreſſively denominates "the power of penetrating into ſpace." The teleſcopes, which are all made under his direction, are of various ſizes, from two feet in length up to forty feet, and the apparatus and machinery with which they are mounted are alſo of his invention, and exhibit a very ingenious diſplay of mechaniſm.

As his larger teleſcopes could not be conveniently managed within the cover of a building, they are mounted in the open air, where they ſtand pointing to the heavens in different directions, and make a moſt magnificent and impreſſive appearance. Thus they are placed in what has been called the primitive obſervatory of man, "non ſub tecto ſed ſub cœlo in puro dio."

His largeſt teleſcope, which La Lande ſays he viewed with aſtoniſhment, is 40 feet long and 5 in diameter. It contains a mirror of about a ton weight; and this great inſtrument, with nearly an additional ton of caſes, &c. is managed by a very ſlight force. It is placed on a large circular frame, which turns on rollers, and the top is ſuſpended by ropes from very lofty ladder-work. Thus, by a ſyſtem of wheels, pinions, racks, and pulleys, the motions, both horizontal and vertical, are given, and hence any celeſtial object is readily found and commodiouſly viewed. It was finiſhed in 1787, and on the firſt trial a new ſatellite of Saturn was diſcovered by it, and a ſecond ſoon after.

For a particular deſcription of Dr. Herſchel's teleſcopes, with their reſpective magnifying and ſpace-penetrating powers, ſee our article TELESCOPE; and for his various diſcoveries, ſee ASTRONOMY, DOUBLE *Stars*, GALAXY, MOON, NEBULÆ, PLANET, SATELLITE, STAR, and SUN. It ſhould be further ſtated here, that a very full and accurate account of his inventions and diſcoveries, as well as a particular deſcription of his teleſcopes and their apparatus, (with plates,) will be found in the Philoſophical Tranſactions, to which he has been a moſt important contributor, having ſupplied that work with nearly 70 elaborate and ingenious communications.

We cannot conclude this ſketch without noticing two of his teleſcopes, of ſmaller ſize, which are famous in the annals of diſcovery. The firſt is a two-feet Newtonian reflector, with which his ſiſter Miſs Carolina Herſchel, whoſe aſtronomical attainments do great honour to her

ſex, diſcovered ſix comets; and the other is his ſeven-feet reflector, by which he diſcovered the Georgian planet at Bath, in 1781.

This teleſcope has, in conſequence of the diſcovery, been made a conſtellation in the heavens with the univerſal approbation of aſtronomers. It is placed between Gemini, the Lynx, and Auriga, and contains 81 ſtars. In Bode's atlas it is engraved with its apparatus, and marked "Teleſcopium Herſchellii."

This effectual mode of conferring immortality has been happily noticed by a ſcientific nobleman, the earl of Roſſe, who lately paid a viſit to Dr. Herſchel, and on ſeeing the doctor's name thus written among the ſtars, applied the following lines from Prior, and immediately added the concluding couplet, which is well worthy of being preſerved.

"Thus the diſtinguiſhed part of men,
With compaſs, pencil, ſword, or pen,
Should in life's viſit write their name
In characters that may proclaim
That they with ardour ſtrove to raiſe
At once their own and country's praiſe."
But Herſchel's fame ſhall higher riſe,
His name is written in the ſkies.

Dr. Herſchel, though in his 75th year, is ſtill an active and indefatigable obſerver. He was born at Hanover, Nov. 15, 1738, a period which will be ever memorable in the hiſtory of aſtronomy.

The King's private Obſervatory in Richmond gardens is extremely beautiful in ſtructure and apparatus, as well as in ſituation. It was built, in 1768, by order of his preſent majeſty George III., who, it is ſaid, made ſeveral obſervations here, particularly of the tranſit of Venus in 1769. It contains a fine tranſit inſtrument, a zenith ſector, and a mural arc, with ſeveral good teleſcopes, eſpecially a ten-feet reflector of Dr. Herſchel's. Here is a ſuperb equatorial on the top of the building, which is covered with a moveable roof. There are alſo two fine orreries, with an excellent collection of philoſophical inſtruments, and ſome caſes of minerals and other natural curioſities. It was built under the direction of Dr. Demainbray, and has been, for ſome years, in the care of Mr. Rigaud.

Oxford Obſervatory is a moſt magnificent ſtructure, and the inſtruments perfectly correſpond with the building. It was begun in 1772, from very ample funds bequeathed by Dr. Radcliffe, and the land on which it ſtands was the gift of the duke of Marlborough. The tranſit inſtrument, which is ten feet long, ſhews very ſmall ſtars in the day-time. It is ſaid to have coſt 150 guineas, the zenith ſector 200 guineas, and the two mural quadrants 600 guineas. There are alſo very excellent teleſcopes and clocks here, the former by Dr. Herſchel and Dollond, and the latter by Shelton. It was built under the direction of Dr. Hornſby, profeſſor of aſtronomy in the univerſity, who obſerved here for many years, and he has been ſucceeded by Dr. Robertſon, the preſent profeſſor of aſtronomy.

The obſervations are all regiſtered, and conſiſt chiefly of the right aſcenſions and zenith diſtances of the ſun, moon, planets, and fixed ſtars. In Dr. Hornſby's time, the regiſtry was ſometimes broken from ill health; for he had no aſſiſtant obſerver: but one has been of late added to the eſtabliſhment, ſo that the obſervations will not, in future, be liable to the like interruptions.

At CAMBRIDGE there have been ſmall obſervatories at Chriſtchurch, Trinity, St. John's, &c. and a plan is ſaid to be now on foot for erecting one upon a great ſcale, and worthy the ſcientific fame of that learned univerſity.

Portſmouth Obſervatory.—At the Royal Marine academy, Portſmouth, there is an obſervatory under the direction of Mr. Profeſſor Inman, which is of peculiar utility, both in teaching the pupils practical aſtronomy, and in finding the rate of time-keepers for ſeamen. It was built and many years ably managed by the late maſter, Mr. Bailey, who had been previouſly aſſiſtant aſtronomer at the Royal Obſervatory, and likewiſe with Capt. Cook in his latter voyages.

At *Chriſt's Hoſpital*, Mr. Wales (who had alſo ſerved under Dr. Maſkelyne and Capt. Cook) erected a ſmall obſervatory at his own expenſe, when he became maſter of the royal mathematical ſchool there; and lately the governors, at the recommendation of Mr. Evans, the preſent maſter, have ordered that the obſervatory ſhall be repaired, and furniſhed with new inſtruments.

The Royal Society have at Somerſet Houſe a ſmall obſervatory, which is generally ſuperintended by the ſecretary for the time being.

At *Highbury Houſe* an obſervatory was built in the year 1787, by Alexander Aubert, eſq., which for perfection of plan and ſplendour of apparatus perhaps has never been equalled by any private individual. This gentleman, whoſe ſcientific and liberal purſuits deſerve honourable mention, died in the year 1806, and his grand collection of inſtruments was diſpoſed of by auction, and of courſe diſperſed. Similar notice may be taken of other obſervatories contemporary with that of Highbury, particularly thoſe of count Bruhl at Harefield, ſir George Shuckburgh, at Shuckburgh, and William Larkins, eſq. at Blackheath, all of which were on a great ſcale, and have been diſcontinued after the demiſe of the owners. Thus in private obſervatories, though the aſtronomers may bequeath their apparatus to their heirs, they cannot transfer either their taſte or their ſcience. It is only in public eſtabliſhments that permanence can be expected.

Among the private obſervatories of the preſent day, the following alphabetical liſt may be alſo mentioned.

Blackheath	-	Stephen Groombridge, eſq.
Blenheim	-	Duke of Marlborough.
Cambridge	-	Rev. Mr. Catton.
Chiſlehurſt	-	Rev. Francis Wollaſton.
Derby	-	William Strutt, eſq.
Eaſt Sheen	-	Rev. William Pearſon.
Finſbury Square		Dr. Kelly.
Godwood	-	The duke of Richmond
Goſport	-	Dr. William Burney.
Hackney Wick		Colonel Beaufoy.
Hayes	-	William Walker, eſq
Highbury Terrace		Capt. Huddart.
Hoddeſdon	-	William Hodgſon, eſq.
Iſlington	-	Gavin Lowe, eſq.
Paragon, Southwark		James Strode Butt, eſq.
Park-lane	-	Sir Harry Engleſield, bart.
Roſe Hill, Suſſex		John Fuller, eſq.
Sherburn	-	Earl of Macclesfield.
St. Ibbs, Hitchen		Mr. Profeſſor Lax.
Woolwich	-	Rev. Lewis Evans.

Scotch Obſervatories.—In the different univerſities of Scotland profeſſorſhips of aſtronomy have been eſtabliſhed, but it has been here, as in moſt other univerſities, the theory of the ſcience has been more attended to than the practice. At Edinburgh and Aberdeen there have been, however, obſervatories; and at Glaſgow there is alſo a ſmall one belonging to the college, but of late a magnificent one has been erected by a ſociety of gentlemen, which is likely, when finiſhed, to be very uſeful as well as honourable to that commercial city.

Iriſh

Iriſh Obſervatories.—In Ireland two obſervatories have been eſtabliſhed on a great ſcale, the one at Dublin, and the other at Armagh.

The obſervatory belonging to Trinity college, Dublin, commonly called the Dublin obſervatory, was begun in the year 1783. It was founded by Dr. Francis Andrews, provoſt of that college, who bequeathed a large income for this purpoſe, which was to commence upon a particular contingency happening in his family. When this event had taken place, the college, with their wonted zeal for the promotion of ſcience, determined not to loſe time by waiting for the accumulation; but advanced from their own funds a ſum conſiderably exceeding the amount of the original bequeſt.

They choſe for their profeſſor of aſtronomy and obſerver the Rev. Dr. Uſher, a man of extenſive learning and indefatigable reſearch, who was directed to proceed to England, to order from Mr. Ramſden the beſt inſtruments he could make, without any limitation of expenſe, and it may be here noticed, that the peculiar anxiety of this eminent artiſt to execute the order in the greateſt perfection, cauſed a conſiderable delay.

The apparatus firſt ordered were, a tranſit inſtrument of ſix feet focal length with a four feet axis, bearing four inches and a quarter aperture, with three different magnifying powers up to 600. An entire circle of ten feet diameter on a horizontal axis for meaſuring meridian altitudes. An equatorial inſtrument, with circles of five feet in diameter: and an achromatic teleſcope, mounted on a polar axis, and carried by an helioſtatic movement. Clocks were alſo ordered from Mr. Arnold, without any limitation of price.

The ſituation choſen for the obſervatory is on elevated ground, about four Engliſh miles N.W. of Dublin. The foundation is a ſolid rock of limeſtone, of ſeveral miles extent; and the ſoil is very favourable, being a calcareous ſubſtance called limeſtone gravel, which is remarkable for abſorbing the rain, and thus contributing to a dry atmoſphere.

The plan of the building unites at once both elegance and convenience: it fronts the eaſt, and the lower range of windows and doors are twenty-three in number. In the centre there is a magnificent dome of three ſtories high, with a moveable roof for the equatorial inſtrument, which is placed upon a pillar of ſixteen feet ſquare, of the moſt ſubſtantial maſonry, and ſurrounded by a circular wall of a foot diſtance, that ſupports the moveable dome, and alſo the floors, which in no part touch the pillar: thus, no motion of the floor or wall can be communicated to the inſtrument. The aperture for obſervation in the dome is two feet and a half wide. For the manner by which the movement of the dome is effected; ſee our article *Rotatory* Roof.

On each ſide of the centre building, and joined to it, are two handſome edifices, of two ſtories high, for the reſidence of the profeſſor, and to each is attached a wing of one ſtory only, but terminated with domes of two ſtories. Theſe domes are intended for occaſional obſervations, ſuch as of eclipſes, occultations, and comets. The wings, however, are not yet completely finiſhed.

But the moſt important erection belonging to this eſtabliſhment is behind the main building, and at right angles to it, in order to obtain an uninterrupted view both north and ſouth. This is the meridian or tranſit room, which contains both the tranſit inſtrument and the circle. It is thirty-ſeven feet long, twenty-three broad, and twenty-one high. Fine pillars of Portland ſtone are erected for both inſtruments on the moſt firm baſis, and the floor is ſo framed as to let all the pillars riſe totally detached from it: and ſuch was Dr. Uſher's attention to extreme accuracy, that he firſt aſcertained the pillars to be perfectly homogeneous, leſt any variety in their ſubſtance might admit of a difference in their expanſion or contraction by heat, cold, or other changes of atmoſphere. The clocks are attached to pillars of the greateſt ſteadineſs alſo: they were made by Arnold, who exerted his beſt ſkill, and are finiſhed in a maſterly manner: the pallets are of ruby; and all the laſt holes of the movement jewelled; the ſuſpenſion ſprings are of gold, with Arnold's own five barred pendulum, and cheeks capable of experimental adjuſtment, ſo as to make all vibrations iſochronal, whatever may be the excurſion of the pendulum.

Such are the plans and apparatus of this ſplendid eſtabliſhment. And we may now for a moment be permitted to turn our attention to the beauties of nature, which are ſtrikingly exhibited in the ſurrounding ſcenery; and which cannot be better deſcribed than in the words of Dr. Uſher himſelf, in the Tranſactions of the Royal Iriſh Academy, vol. i. p. 13

"Around the dome is a platform commanding one of the moſt extenſive and varied proſpects that can be imagined. On the ſouth of the obſervatory there is a view of the grounds of lord Bective, with a gentle declivity to the river, and from thence a varied picture of the rich ſcenery of the woods of the Phœnix park, terminated in the back ground by the majeſtic grandeur of the Wicklow mountains. To the ſouth-eaſt we have the city of Dublin, diſtant four miles, the ſemicircular bay, with the ſhipping and the great ſouth wall extending five miles into the ſea, and terminated by the light-houſe; the ridge of rocky hills, called the Three Brothers, forming the head of Dalkey, and bearing Malpas's obeliſk on the higheſt point. Nearly in this direction, in particular ſtates of the atmoſphere, the Welſh mountains are diſtinctly viſible. On the eaſt and north-eaſt of Clontarf and its environs are the Hill of Howth, Ireland's Eye, and Lambay. From thence to the north-weſt the proſpect is ſo uncommonly level and extenſive as to gratify the aſtronomer much more than the painter; but even this variety is not without its beauty. To the ſouth-weſt we have the pictureſque ruins at Caſtlenock, and to the weſt the extended and rich view of Kildare, in which Mr. Conolly's obeliſk forms a grand and central object."

Dr. Uſher did not, however, long enjoy the beauties of this ſcenery, nor the pleaſures of aſtronomy. He died in 1790, before the inſtruments had been all ſupplied. He was ſucceeded by the Rev. Dr. Brinkley, who had diſtinguiſhed himſelf at Cambridge by profound analytical inveſtigations, and who has ſince greatly enriched the Tranſactions of the Royal Iriſh Academy by mathematical and aſtronomical communications. His labours in practical aſtronomy, however, have been greatly impeded by the doubts and indeciſion of Mr. Ramſden, particularly in the conſtruction of the ten-feet circle, upon which very delicate and important operations depended. After making ſome progreſs in this inſtrument, he rejected it, and began another of nine feet diameter, which he proceeded in ſo far as actually to divide it, and this he rejected alſo, and fixed upon one of eight feet, which was left unfiniſhed at his death. After ſome years labour, his ſucceſſor, Mr. Berge, finiſhed the circle in a moſt accurate manner; and hence it was not placed in the obſervatory until July 1808, a delay which muſt have greatly circumſcribed the utility of the inſtitution. Ramſden's indeciſion is ſuppoſed to have ariſen from an opinion which he latterly formed, that very large inſtruments are moſt liable to get out of adjuſtment.

From this new circle in the hands of Dr. Brinkley, important reſults are expected, particularly on parallax, aberration of light, and refraction. He has been for ſome time engaged in a ſeries of obſervations with a view to explain the cauſe of variations that he has found in the zenith diſtances of certain ſtars at different times, which do not ſeem explicable

explicable by any cauſe at preſent generally allowed. He has found a difference between the zenith diſtances of α Lyræ, when in oppoſition and conjunction, which may be explained by a parallax of about two ſeconds. Such a parallax is, however, doubted; but it is by aſtronomers who have not had perhaps the accurate means, which he poſſeſſes, of referring their obſervations to the zenith. The new tranſit circle juſt erected at Greenwich poſſeſſes this advantage, and great hopes may therefore be formed from the concurrent operations of thoſe two inſtruments.

Armagh Obſervatory.—At Armagh, the metropolitan city of Ireland, and anciently the ſeat of a large univerſity, there has been an obſervatory erected and endowed in 1793, by the moſt reverend Richard lord Rokeby, primate of all Ireland, who diſtinguiſhed himſelf upon various other occaſions by very liberal grants for the diffuſion of ſcience and literature. Beſides founding a collegiate ſchool, and public library, he bequeathed a large ſum towards an object which he had always much at heart, the re-eſtabliſhment of a univerſity in this city, and it is ſaid that he thought this plan would be greatly promoted by previouſly erecting an obſervatory and muſeum here, which his lordſhip accompliſhed at the expenſe of about 15,000*l.*

The obſervatory is erected on the ſummit of a gently riſing hill, about 90 feet above the general level of the town, and ſurrounded by ſeveral undulating hills all nearly of the ſame altitude. This building is founded on a baſe of limeſtone, and all the walls are of large hewn ſtone, and of the moſt firm and ſubſtantial workmanſhip. The tower, which joins the dwelling houſe, contains a very fine equatorial by Troughton, fixed upon a large pillar, which is raiſed ſo high that the inſtrument in the dome can overlook all the buildings. To the eaſt of the houſe is a range of buildings for the tranſit room, and other aſtronomical purpoſes. The principal inſtruments, beſides the equatorial and tranſit, are a ten-feet ſextant by Troughton; a ten-feet reflecting teleſcope by Dr. Herſchel; a five-feet triple object-glaſs achromatic teleſcope by Dollond; and alſo a fine night glaſs upon an equatorial ſtand. The clocks are by Earnſhaw of London, and Croſsthwaite of Dublin.

In this eſtabliſhment a liberal income is allowed to the principal aſtronomer, and a good ſalary to his aſſiſtant. It has been ſuperintended from the beginning by the Rev. James Archibald Hamilton, D. D. dean of the cathedral church of St. Coleman, Cloyne, who has contributed ſeveral learned papers to the Tranſactions of the Royal Iriſh Academy, chiefly on aſtronomical ſubjects. His obſervations, particularly on the fixed ſtars, are conſidered very accurate, and ſome of his declinations have been tranſcribed into the Philoſophical Tranſactions of the Royal Society of London in 1806.

The regiſtered obſervations here are thoſe made with the tranſit inſtrument and equatorial; and alſo an account of the temperature and weight of the atmoſphere. Of theſe, a ſeries of about eighteen years is preſerved. The right aſcenſions of the ſun and moon, compared with the fixed ſtars, are regular and unbroken; but their north polar diſtances have not been ſo conſtantly taken, as they are only obſerved by the principal aſtronomer, whoſe paſtoral duties muſt occaſionally interfere with his aſtronomical labours.

It may be finally noticed, that there are belonging to this eſtabliſhment about 20 acres of plantation and pleaſure grounds, which are open for the recreation and health of the inhabitants of the city. Thus the views of the benevolent founder extended to various kinds of good. He ſpent a long life in acts of public and private beneficence, and his laſt work was the obſervatory, which he began in his 84th year; and which he juſt lived to ſee finiſhed.

General Directions for Building and Furniſhing Obſervatories.—The deſcriptions of the principal obſervatories in the foregoing columns have been the more minute, as ſuch may be ſuppoſed to convey more inſtruction than general directions; we ſhall, however, inſert here a few additional hints, which may likewiſe be found uſeful.

In building an obſervatory, attention ſhould be paid to ſituation, ſoil, and foundation, as well as to ſtructure; and in furniſhing one, regard muſt be had both to the proper choice, and convenient diſpoſition of inſtruments.

The *ſituation* ſhould be ſufficiently elevated to command a view of the horizon, eſpecially to the north and ſouth; but very high places are not eligible, as they moſtly attract clouds, and are in other reſpects too much expoſed to the ſeverities of weather.

In chooſing a ſituation, it will be requiſite to make preparation for a meridian mark, and for this purpoſe it would be convenient if the obſervatory could be placed in the meridian line of ſome building, or other permanent object, upon which the mark may be made, and this is done as ſoon as the tranſit inſtrument is ſet correctly in the meridian, by which it may be afterwards regulated. (See TRANSIT *Inſtrument*.) If two meridian marks can be ſet up, one north, and the other ſouth, it will be deſirable, and they ſhould not be leſs than 500 yards diſtant from the obſervatory: the farther the better, provided they are viſible. The obſerver ſhould have free acceſs to them, as it may be neceſſary ſometimes to illuminate them by night. Theſe marks ought to be nearly on the ſame level, and not ſubject to be obſcured by groſs exhalations, as ſuch are ſuppoſed to create horizontal refractions, and to make the marks appear out of the meridian.

The *ſoil* ſhould be naturally dry, which is generally the caſe when it is of a gravelly or ſtony kind; but clay ſoils that do not ſoon abſorb the rain cauſe exhalations and damps, which not only injure the inſtruments, and obſcure the atmoſphere, but greatly increaſe the irregularities of refraction.

The *foundation* ſhould be of the moſt ſolid kind, and therefore a rock of ſome extent, or a hard gravel, ſhould be choſen, and where ſuch cannot be had, all adventitious firmneſs ſhould be obtained either by conſtructing deep arches, or by piles driven with an engine; for ſuch is the perfection of modern inſtruments, that they immediately betray any defect in the building, whether ariſing from the foundation, or ſuperſtructure.

The *building* ſhould therefore be of ſolid and ſubſtantial maſonry, particularly the tranſit room, which is the moſt eſſential apartment of an obſervatory. This room ſhould, for the ſake of firmneſs, be on the ground, and the pillars which ſupport the inſtruments and clocks ſhould be detached from the floor. It ſhould of courſe poſſeſs a good view both north and ſouth, and the opening or meridian aperture for obſerving through ſhould command an uninterrupted view from the zenith to the horizon, in both directions; and the ſhutters or covers of the apertures ſhould be opened and ſhut with eaſe by pullies, or other ready methods. The proper width of the meridian apertures has been a ſubject of ſome doubt; but it is generally agreed that they ſhould be wide enough for pointing the inſtrument conveniently to the heavens, and for admitting a ready ſupply of freſh air into the obſervatory, ſo as to render the internal temperature equal to the external; and if the ſhutters be divided into ſmall openings, ſuch may be occaſionally uſeful to prevent a very hot ſun from affecting the adjuſtment of the inſtrument.

With reſpect to the other apartments, their number muſt depend on the number of inſtruments to be uſed, whether

at the ſame time, or in ſucceſſion. In moſt large obſervatories there is a dome raiſed for the equatorial or the circular inſtrument; for the plan of which, ſee *Rotatory* ROOF.

As to the choice of inſtruments, and their convenient diſpoſition, regard muſt be had to the plan of building; and the number muſt alſo depend on the ſame, as well as on the number of obſervations to be made. An obſervatory, however, cannot be conſidered as well furniſhed without the following apparatus: a tranſit inſtrument, or mural tranſit circle, with good clocks to ſhew both ſolar and ſidereal time; and chronometers alſo are often uſeful. Mural quadrants or ſextants may be likewiſe mentioned; but entire circles are greatly preferable, as they admit of various ſelf-correcting adjuſtments, particularly when fitted up with revolving microſcopes. A portable reflecting circle ſhould alſo form part of the apparatus, in order to meaſure angular diſtances in all directions, horizontal, vertical, and oblique. If there be a circular inſtrument that will meaſure both altitudes and azimuths, or an equatorial inſtrument, then a moveable dome will be neceſſary.

A zenith ſector is likewiſe of importance, and of courſe good teleſcopes are eſſential, eſpecially an achromatic with an equatorial movement and a micrometer eye-piece; alſo a powerful reflector for obſerving the phaſes of the ſun, moon, and planets, as well as the ſatellites, nebulæ, &c.

A particular deſcription of the various inſtruments of an obſervatory will be found in this work, under their proper heads, with rules and examples for their uſe and application.

A TABLE of the Longitudes and Latitudes of the principal Obſervatories of Europe, as deduced from the moſt recent and accurate Determinations.

Note. The ſign — denotes Eaſt Longitude, and the ſign + Weſt Longitude, by which it is to be underſtood that addition or ſubtraction muſt be applied to the time of any given place, in order to find the correſponding time at the Greenwich Obſervatory.

OBSER-

OBSERVATORY, *Portable*. See EQUATOREAL.

OBSERVATORY *Iſland*, or *Padevoua*, in *Geography*, a ſmall iſland in the South Pacific ocean, near the N.E. coaſt of New Caledonia. S. lat. 20° 18′. E. long. 165° 40′.

OBSERVATORY *Iſland*, a ſmall iſland in the ſtraits of Magellan, at the entrance of Bougainville bay.

OBSERVATORY *Point*, a cape on the N. coaſt of the iſland of Tongataboo. S. lat. 21° 8′. E. long. 184° 55′.

OBSERVATORY *Inlet*, an inlet on the W. coaſt of North America, where Capt. Vancouver made his obſervation; extending about 32 miles, N. lat. 54° 58′. E. long. of the entrance 230° 6′.

OBSESSION, an action, or rather paſſion, of being beſet by an evil ſpirit; which, without entering the body, torments, and, as it were, beſieges the perſon without. In which ſenſe, obſeſſion differs from poſſeſſion.

The marks of obſeſſion, according to ſome, are a being hoiſted into the air, and thrown violently down without being hurt; ſpeaking languages never learnt; having an averſion to all acts and offices of religion, &c.

Some phyſicians look on all caſes of obſeſſion as natural, and curable by natural medicines, particularly by an unguent, called *unguentum corriobieri*; with purgatives, or vomitives.

Of this opinion is Dr. Gabriel Clauderus, member of the Leopoldine Academy, which he confirms with the teſtimony of Fromannus, in his treatiſe "De Faſcinationibus," and Ganſius de Corallis; adding, that it has been confeſſed by many witches and ſorcerers, that the plant hypericon, and other ſimples, &c. incommode them terribly, and prevent their operations.

He confirms this ſentiment hence, that the devil, in thoſe he thus beſets, makes uſe of the melancholic humour, or the atra bilis, and the groſſer impurities of the blood, without always acting immediately of himſelf. For which he refers to the books of Melchior Sebizius, and Jerom Jordan "De Divino in Homine;" and gives the proceſs of a cure of a manifeſt obſeſſion of a child of a year old at Delitſchebourgh, three leagues from Leipſic. In truth, the devil hath no ſhare in the matter. See DÆMONIACAL *Poſſeſſion*.

OBSIDIANUS LAPIS, in the *Natural Hiſtory of the Ancients*, the name of a ſtone which they have alſo deſcribed under the name of the *China marble*. It is very ſmooth and hard, extremely difficult to cut, but capable of a fine poliſh, and was uſed among the ancient Greeks for the making of reflecting mirrors.

The later writers have ſuppoſed the name obſidianus derived from ſomebody of the name of Obſidius, who was the inventor of this uſe of it; but it ſeems only a falſe ſpelling of the word *opſianus*, απο της οψεος, from ſeeing the images of things in it.

The obſidian, or Iceland agate, occurs in maſs, and alſo in rough, roundiſh, detached pieces. Its ſpecific gravity is 2.34. The obſidian of Iceland has been decompoſed by Bergman, and more recently by Abildgaerd, with the following reſults:

Berg.		Abild.	
69	-	74	Silex
22	-	2	Alumine
9	-	14	Oxyd of iron.
100		90	

The hardneſs and opaque blackneſs of this mineral, added to the high poliſh of which it is capable, have cauſed it to be employed for various kinds of ornaments. In Peru, at the time of its conqueſt by the Spaniards, it was uſed for mirrors, and has been faſhioned in Europe into reflectors for teleſcopes. See AGATE and LAVA, Claſs 10.

OBSIDIONALIS, an epithet which the Romans gave to a ſort of crown with which they honoured ſuch of their generals as had delivered a Roman army, or fortreſs, beſieged by the enemy; and had raiſed the ſiege, or obliged them to decamp.

The word comes from the Latin *obſidio*, *ſiege*.

It was alſo called *graminea*, becauſe made of graſs or herbs found on the ſpot or ſoil.

It was the ſoldiery who beſtowed this crown; which, doubtleſs, was the reaſon of its not being of a more precious matter.

OBSKAIA, in *Geography*, a gulf or bay of Ruſſia, in the Frozen ocean, about 360 miles in length, and from 44 to 60 in breadth. N. lat. 66° 40′ to 72° 15′. E. long. 72° to 76°.

OBSTACLES *to Cultivation of Land*, in *Agriculture*, any ſort of impediments placed in the way of its improvement. Theſe are of various kinds, ſuch as ariſe from too much water below or on the ſurface of the ground, and which can only be removed by ſuitable kinds of draining; from the growth of wood either of the ſtrong or more ſhrubby ſorts, and which can only be made capable of cultivation, by being wholly cleared away and deſtroyed both in the root and top; and from ſtones of the rocky or other deſcriptions, either lying below or above the ſurface of the ground, and which require to be wholly, or in a great part, removed before any ſort of cultivation can be attempted. All theſe, and various others of a leſs obvious tendency, are frequently met with by the cultivator, and often oppoſe conſiderable obſtruction to the progreſs of his improvements, in bringing land into the ſtate of cultivation. See DRAINING.

But though theſe are ſome of the principal obſtacles that preſent themſelves from the nature of the lands themſelves; there are others which ariſe from the nature of the tenure or manner in which they lie or are held, and various other cauſes which do not depend upon the land. Theſe have been ſtated by Dr. Robertſon, in his Agricultural Survey of the County of Perth, to be, firſt, *townſhips*, by which he means a number of *plough-gates* in one village, or ſeveral tenants about one plough; ſecondly, the cuſtom of *runrig*, or an intermixture of property; thirdly, the *uncertain boundaries* of eſtates; fourthly, the feudal cuſtom of ſervitudes, which are productive of various ill conſequences; fifthly, the cuſtom of thirlage to mills; ſixthly, the *ſhortneſs* of leaſes; ſeventhly, the *diſtance* from manure; and eighthly, *commons*, or lands in the ſtate of commonage. But beſides theſe, the taking of tithes in kind, and ſome other claims upon land, operate unfavourably to their cultivation. The particular methods in which theſe different cauſes operate in preventing the cultivation of lands, will be explained in ſpeaking of the ſeveral heads to which they particularly relate.

ORSTETRICAL ART, the art of midwifery. See DELIVERY, and LABOUR.

OBSTITA, among the Romans, a term uſed to ſignify places that had been thunder-ſtruck, which were otherwiſe called *bidentalia*. See BIDENTAL.

OBSTRUCTION, in *Medicine*. Any tumour or collection of matter, natural or morbid, which occaſions an impediment to the regular performance of the functions of any organ in the body, is ſaid to be an obſtruction. Such are the accumulation of excrement in the inteſtinal canal, or of bile in the ducts of the liver; the effuſions of ſerum in various cavities of the body, conſtituting hydrothorax, aſcites, and other

other ſpecies of dropſy; and the occurrence of all large tumours in the viſcera, which, by preſſure upon the contiguous organs, interrupt and derange their action. All chronic enlargements of the glands and other parts tend, by ſuch preſſure, to obſtruct the proper circulation and excretion of the fluids, and therefore to produce various ſecondary or ſymptomatic diſeaſes. Thus ſcirrhous tumours of the meſentery, pancreas, or of the liver itſelf, by preſſing upon the vena portæ, or great veſſel of the liver, are liable to produce dropſy of the belly, in conſequence of impeding the circulation of the blood through the veſſels of the abdomen, which therefore pour out the thinner or watery part of the blood into the cavity of the belly, from their exhalent extremities. The ſame tumours, if they preſs upon the bile-ducts, will impede the flow of the bile into the inteſtines, and occaſion jaundice. In a ſimilar manner, the functions of the lungs, heart, kidnies, brain, and every other organ of the body, are deranged by obſtructions, occurring within their own ſubſtance, or in the adjoining parts.

As obſtructions are ſeated in organs of various ſtructure, and conſiſt of diſeaſed changes of various nature, the proper treatment of the diſeaſes which they produce, can only be directed with ſucceſs, after a careful and ſkilful inveſtigation of the various ſymptoms connected with them. The connection of certain ſymptoms, with certain organic derangements of the internal parts, is learnt by an obſervation of the functions, which are particularly diſordered, aided by the knowledge acquired by previous examinations of the diſeaſed organs after death, and by a compariſon of them with the ſymptoms that had occurred during life. Hence the ſtudy of what is called morbid anatomy is of great importance in enabling the phyſician to aſcertain the nature of diſeaſes originating from organic obſtructions; and it muſt be obvious, that the univerſal adminiſtration of any particular remedy, as a deobſtruent, will be often altogether uſeleſs, and not unfrequently injurious.

The various diſeaſes, originating from obſtruction, will be found under their reſpective heads. See Dropsy, Jaundice, Marasmus, &c.

OBSTRUENTS. See Deobstruent.

OBSTRUXIT, *Quare* Obstruxit. See Quare.

OBTUNDENTIA, a word uſed by ſome authors to expreſs ſuch medicines as are given to obtund, or edulcorate the acrimony of the humours.

OBTURATOR, in *Anatomy*, an epithet applied to the large oval opening in the front of the os innominatum, and to various parts ſituated near it. The opening is called the obturator foramen; the ligament which occupies it, an artery, a vein, a nerve, and two muſcles, have the ſame epithet.

The *obturator externus* (ſous-pubo-trochanterien externe) is a muſcle of a triangular figure, ſituated at the upper and inner part of the thigh, and extending from the foramen ovale of the pelvis to the great trochanter. It ariſes from the anterior part of the bone forming the foramen ovale, and from the neighbouring portion of the obturator ligament. It grows narrower, and paſſes outwards and backwards, lying on the obturator ligament, on the iſchium, and on the orbicular ligament of the hip. It then aſcends behind the neck of the femur, and is fixed by a tendon to the lower part of the internal ſurface of the great trochanter, adhering firmly to the orbicular ligament. It is covered in front by the pectinalis, the adductors, and the quadratus. The upper edge is rather concave, and extends obliquely from within outwards, and from above downwards, from the pubes to the great trochanter: the obturator veſſels and nerve come over it towards the inſide, and it is connected, on the outſide, by cellular tiſſue, to the orbicular ligament. The inferior margin is nearly tranſverſe in its direction. The poſterior ſurface covers the obturator ligament, and a part of the bone.

This muſcle is fleſhy at its origin, and in moſt of its ſubſtance; but its attachment to the trochanter is tendinous.

It rotates the thigh-bone outwards, and draws it towards the oppoſite limb.

The *obturator internus* (ſous-pubo-trochanterien interne) is another muſcle of the thigh, very ſimilar to the former in ſize and direction, but placed within the cavity of the pelvis. It is flattened and triangular in its figure, and reaches from the foramen ovale to the trochanter major. It ariſes from the upper, lower, and internal edge of the foramen ovale, and from the obturator ligament. The fibres converge and form a tendon, which turns round the bone in the groove between the tuberoſity and ſpine of the iſchium, and paſſes out of the pelvis at the leſſer ſacro-ſciatic foramen. It then runs from within outwards, between the two gemini, which almoſt entirely cover it behind, and terminates by an inſertion in the back of the trochanter major.

The internal ſurface of this muſcle is covered by the levator ani, and the pudendal veſſels; the external covers the obturator ligament, and a part of the iſchium. On the outſide of the pelvis, the tendon lies upon the iſchium and the hip-joint, with the gemelli more or leſs cloſely adhering to it.

An interval is left between two portions of the muſcle, at its origin, and gives paſſage to the obturator veſſels and nerve.

The origin is fleſhy, and comparatively broad; the muſcle has become narrow where it turns round the iſchium, and it is ſtill narrower on the outſide of the pelvis, where it is almoſt entirely tendinous. A very well-marked burſa mucoſa covers the tendon and bone, where the former turns over the latter. The ſurface of the bone is covered by cartilage, over which, and over the correſponding ſurface of the tendon, a ſynovial membrane is extended. This burſa extends ſome way into the pelvis. From the ſharp turn which the muſcle makes over the bone at this part, the rubbing in its action muſt be very conſiderable: we find the bone here marked by ſeveral riſings, correſponding to diviſions in the tendon.

The obturator externus rotates the thigh-bone outwards: when the hip is bent, it will ſeparate the thigh from the oppoſite limb.

OBTUSE literally imports blunt, dull, &c. in oppoſition to acute, ſharp, briſk, &c.

Obtuse *Angle*, in *Geometry*. See Angle.

Obtuse-*Angled Triangle*, is a triangle, one of whoſe angles is obtuſe.

Obtuse-*Angular Section of a Cone*, a name given to the hyperbola by ancient geometricians, becauſe they conſidered it only in ſuch a cone, whoſe ſection by the axis is a triangle, obtuſe-angled at the vertex. See Conic *Sections*, and Hyperbola.

Obtuse *Appui*. See Appui.

OBVA, in *Geography*, a river of Ruſſia, which runs into the Kama, near Obvinſk.

OBVENTIONS, Obventiones, in *Ancient Law Books*, ſignify the produce of a benefice, or ſpiritual living; including oblations, tithes, rents, and other revenues.

OBVINSK, in *Geography*, a town of Ruſſia, in the government of Perm, on the Kama; 60 miles N. of Perm. N. lat. 58° 44′. E. long. 56° 14′.

OBY, or Ob, the largeſt river in the Ruſſian empire, anſwering to its name, which ſignifies "Great," originates

properly in the Chineſe Soongoria, from whence it iſſues in a copious ſtream, under the appellation of Tſhuliſhman; and in N. lat. 52, and E. long. 103° 30′, falls into the lake Teletzkoe, in the Ruſſian territory. From this lake, called by the Tartars Altinkul, or Altyn, it flows out again under the name of By, not taking that of Oby until its junction with the Katunya. In its upper regions it has a ſtrong current, and ſeveral cataracts, and particularly a great number of iſlands, moſtly in the circle of Beroſof. At N. lat. 67°, and long. 86°, it diſcharges itſelf into the gulf of the ſame name, which unites it with the Frozen ocean in N. lat. 73° 50′, and long. 90°. The principal rivers which the Oby takes up in its courſe are to the left, the Katunya, the Tſharyſh, the Alei, the Irtyſh, the Konda, and the Soſva; to the right, the Tſhumyſh, the Tom, the Tſhulym, the Ket, and the Voch. Up as far as the mouth of the Ket, the Oby has moſtly high and rocky ſhores; but farther on, quite to its entrance into the Frozen ocean, it, generally ſpeaking, flows over a clayey, ſandy, and marly bed. It is navigable till very near up to the Teletzkoe Ozero, uncommonly prolific in fiſh, and in many places is accompanied by foreſts of large pine and birch trees. The courſe of this river extends above 3000 verſts. Tooke's Ruſſia, vol. i.

Oby, or *Ouby*, a ſmall iſland in the Eaſt Indian ſea; 50 miles in length from E. to W., and from 12 to 20 in breadth. S. lat. 1° 36′. E long. 124° 56′.

Oby, *Little*, a ſmall iſland near the W. coaſt of Oby. S. lat. 1° 26′. E. long. 127° 12′.

OCADH, a town of Arabia, in the province of Hedsjaz; 30 miles N.E. of Niab.

OCAMPO, Florian de, in *Biography*, a perſon of whom little is known, except what is learnt from a petition which he preſented to the Cortes of Valladolid, a few months before his death. In this petition he ſtated, that for twenty-eight years he had been employed upon the Chronicle of Spain, in conſequence of which he had been appointed chronicler to the emperor Charles V. in 1539. In 1547 he was made a canon of Zamora, but the duties of this ſtation deprived him of all leiſure for literary purſuits, and he therefore petitioned for a penſion of 400 ducats, being equivalent to the value of the preferment. This was favourably received, but Ocampo did not live to receive it. He took great pains in travelling through many countries in queſt of documents for his hiſtory, and boaſts of having copied every inſcription in Tarragona with his own hand. He ſays, he went down into the mine near Carthagena, not without riſk to his perſon. He had travelled abroad, and was once driven by ſtorms on the coaſts of Ireland. His chronicle only comes down to the death of the Scipios. After relating the fall of Syracuſe, Florian devotes a whole chapter to Archimedes; in this, he ſays, he wiſhed to indulge his own feelings, "becauſe it ſeems to me, that if chroniclers would look to this, it would be a more fitting thing to record in hiſtories, the remembrance of perſons ſo uſeful to the world, ſo worthy to have their inventions and benefactions praiſed by us all who come after them, than the cruelty and fierceneſs of ſo many battles, ſo much ſtrife and rancour, ſuch waſte of blood as we find to be their main ſubject of relation, being manifeſtly things injurious to our nature, and which ſhould be lightly related, or paſſed over in ſilence, as of bad example, when not called forth for the ſupport or defence of virtue, or of princes and good rulers, whom God commands us to regard in his place." Florian ſpeaks of a work that he deſigned to write upon mechanical inventions, which he had ſeen in his travels, and on ſome of which he had improved, with the view of ſetting forth the manner to be uſed in making them, and afterwards the reaſon and cauſes of all their effects and circumſtances, conformable to the principles of natural philoſophy. This writer is ſaid to have rendered more ſervice to Spaniſh literature, as an editor, than as an author. During his reſidence at Zamora, the printers of that city applied to him for ſomething to write, which they might publiſh for the uſe and glory of the kingdom. He fortunately had in his poſſeſſion the General Chronicle of Spain, which had been compiled by Alfonzo the Wiſe, which he gave them for the preſs, and he corrected the proofs with great care, and the moſt ſcrupulous fidelity. This edition was completed in December 1541, and is a very fine black letter book. There is a Valladolid edition of it of 1604, but the work is very rare. This author, ſays Mr. Southey, was born in 1499, and died in 1555. His father's name was Lope de Ocampo, who was natural ſon of D. Diego de Valencia, by Sancha Garcia de Ocampo. Gen. Biog.

OCANNA, in *Geography*, a large and antique city of Spain, and chief town of Lower Mancha, ſituated on an eminence on the ſide of New Caſtile and La Mancha, at the entrance of the plain of La Meſſade Ocanna. This place was formerly very ſtrong, and the remains of the old walls are ſtill viſible. It belonged for ſome time to the order of Calatrava; and was afterwards transferred to the knights of St. James, to whom it now belongs. In later times it has loſt much of its ſplendour, and is now partly in ruins. Ocanna contains four pariſhes, ſix monaſteries, five convents, a governor of the order of St. James, and an Alcade mayor. The inhabitants formerly carried on a conſiderable trade in gloves; it had 72 manufactories, and 103,480 dozen pair were ſaid to be made every year; but the importation of this article has put a ſtop to that branch of induſtry and commerce. It has now only one manufactory of leather for ſhoe-ſoles, and four of hard ſoap. The church of the Carmelites is the only edifice worthy of notice. One of its two fountains is grand and noble; and, as ſome ſuppoſe, was built in the reign of Philip II., but others think it more probable, that it was conſtructed at the time when the grand maſters of St. James, then ſo rich and powerful, lived at Ocanna; and, therefore, at a much earlier period than the reign of Philip II. The number of inhabitants is about 2000; 25 miles E.N.E. of Toledo. N. lat. 40° 1′. W. long. 3 47′.

Ocanna, or *St. Anna*, a town of South America, in the province of St. Martha, on the Rio di Oro; 220 miles S. of St. Martha. N lat. 7° 50′. W long. 73° 26′.

OCCA, a ridge of mountains in Spain, being one of the principal ramifications of the Pyrenees, extending from the vicinity of Tortoſa in Catalonia, to Burgos in Old Caſtile.—Alſo, a river of Spain, which riſes near Burgos, and runs into the Ebro near Frias.

OCCACOKE, an iſland near the coaſt of North Carolina; 10 miles long, and from $1\frac{1}{2}$ to 3 wide. N. lat. 36°. W. long. 76° 12′. A channel between this iſland and Cove bank is called Occacoke inlet. N. lat. 34° 55′. W. long. 76° 18′.

OCCAM, William, in *Biography*, an Engliſh ſcholaſtic divine of the 14th century, was a diſciple of Dun Scotus, to whom he was little, if at all, inferior in ſubtlety, and obtained the title of the "Invincible Doctor." He became a member of the order of Cordeliers, the general of which appointed him to write againſt pope John XXII.; the reſult of this was the work entitled "De poteſtate Eccleſiaſtica et Seculare," in which he boldly oppoſed the tyranny of the papal over the civil power. He was obliged, in conſequence of this piece, which expoſed the encroachments of the Roman ſee, and the corruptions of the monks, to betake

take himſelf to flight. He eſcaped from Avignon in 1327, and proceeded to Munich, where the emperor then was whoſe protection he ſought. Under his auſpices he again maintained the independency of the civil power, with reſpect to the eccleſiaſtical. He was joined by others, but Occam ſurpaſſed them all in the keenneſs and ſpirit of his ſatire, and hence it is thought that his "Dialogues between a Maſter and Scholar," and his other pieces intended to expoſe papal tyranny, were peruſed with avidity, and had no little effect in preparing the way for the downfall of the ambition and greatneſs of the popes. This oppoſition to the ſee of Rome drew down upon Occam a ſentence of excommunication, but he continued to live in ſecurity in the emperor's court, where he died in 1347. He was author of many works beſides thoſe already referred to, particularly of "Commentaries" on ſome of the pieces of Porphyry, Ariſtotle, and the ſentences of Peter Lombard. They were collected in 1476, and publiſhed at Paris in two volumes folio. Enfield's Hiſt. Phil. vol. ii.

OCCASIO, in *Ancient Law Writers*, denotes a tribute which the lord impoſed on his vaſſals, or tenants, on occaſion of war, and other exigencies.

OCCASIONAL Cause, &c. See Cause, Efficient, &c.

OCCATION, a term in the ancient huſbandry, by which they expreſſed what we do by harrowing, though they performed it with a different inſtrument, a kind of rake. With the teeth of this inſtrument they levelled the ground, and broke the clods, and, with the hand, ſtrewed the corn over this level ground. Then they brought on the plough, and ploughed it in; ſo that the grain was ſown in furrows, as we expreſs it, and uſually came up, as we ſee it does at this time with us, in the ſame caſe, in the lower parts only. After it had got a few leaves, they went over the ground again with the ſame inſtrument a ſecond time, to clear away the weeds, and move the earth about the roots of the young plants. If they did this lengthways of the furrows, the earth being ſomewhat hardened, there fell but little of it among the corn; but if they did it croſſways of the furrows, a great deal fell down upon, and among, the young plants, and, in a manner, buried them: they were uſually obſerved to grow better for this croſs harrowing, except in cold places; and the huſbandmen thought the vigour of the plants was owing to the burying them with new earth; but this was really rather prejudicial to them, and the advantage they had aroſe from the more deep ſtirring of the ground. Tull's Huſbandry.

OCCHIO, in *Glaſs Making*, the hole of the floor of the tower of the leer.

OCCIDENT, in *Geography*, the weſtward quarter of the horizon, or that part of the horizon where the ecliptic, or the ſun therein, deſcends into the lower hemiſphere.

Occident, *Equinoctial*, that point of the horizon where the ſun ſets, when entering Aries or Libra.

Occident, *Eſtival*, that point of the horizon where the ſun ſets at his entrance into the ſign Cancer, when the days are longeſt.

Occident, *Hybernal*, that point of the horizon where the ſun ſets, when entering the ſign of Capricorn; at which time, the days, with us, are ſhorteſt.

OCCIDENTAL, a term chiefly uſed in commerce, to diſtinguiſh commodities brought from the Weſt Indies, *i. e.* America, from thoſe brought from the Eaſt Indies, which are ſaid to be *oriental*.

In this ſenſe we ſay, occidental bezoar.

Occidental *Pearl*. See Pearl.

Occidental *Horizon*. See Horizon.

OCCINIANO, in *Geography*, a town of France, in the department of the Marengo; ſeven miles S.W. of Caſala.

OCCIPITALIS, in *Anatomy*, an epithet applied to the parts ſituated about the occiput, as an artery, vein, nerve, &c.

Occipitalis *Muſculus*. See Epicranius.

OCCIPITIS Os, a bone of the cranium. See Cranium.

OCCIPITO-Frontalis, a muſcle of the ſcalp. See Epicranius.

OCCIPUT, the back of the cranium, forming the protuberance immediately above the neck; or the particular bone forming that part of the ſkull.

OCCOA, in *Geography*, a bay on the S. ſide of the iſland of St. Domingo, into which fall the rivers Sipicepy and Ocoa. It lies E. of Neybe or Julienne bay, and is bounded S.E. by point Salinas, and W. by the E. point at the mouth of Bya river.

Occoa, a bay near the E. coaſt of the iſland of Cuba, in the Windward paſſage, about 20 miles E. of Guantanamo bay.

OCCOCHAPPY, or *Bear-Creek*, a river of America, in the Miſſiſippi territory, which diſcharges itſelf through the S.W. bank of Tenneſſee river, juſt below the Muſcle ſhoals. From this creek to the navigable waters of Mobile river, there is portage of about 50 miles.

OCCONEACHEA Islands, two long narrow iſlands at the head of Roanoke river, in Virginia, juſt below where the Staunton and Dan unite and form that river.

OCCULT, ſomething ſecret, hidden, or inviſible. The occult ſciences are, magic, necromancy, cabbala, &c.

Agrippa has ſeveral books of occult philoſophy, full of the vaineſt, wildeſt dreams imaginable: and Fludd nine volumes of the cabbala, or occult ſciences, wrapt up under figures or Hebrew characters.

Weak philoſophers, when unable to diſcover the cauſe of an effect, and unwilling to own their ignorance, ſay, it ariſes from an occult virtue, an occult cauſe, an occult quality.

Occult, in *Geometry*, is uſed for a line that is ſcarcely perceivable, drawn with the point of the compaſſes, or black-lead pencil.

Occult, or dry lines, are uſed in ſeveral operations; as the raiſing of plants, deſigns of building, pieces of perſpective, &c. They are to be effaced when the work is finiſhed.

OCCULTATION, in *Aſtronomy*, the time a ſtar or planet is hid from our ſight, by the interpoſition of the body of the moon, or of ſome other planet. See Eclipse.

Occultation, *Circle of Perpetual*. See Circle.

OCCUPANT, in *Law*, he that firſt ſeizes and takes poſſeſſion of a thing.

If a tenant hold land, &c. for the term of another's life, and ſuch tenant die firſt, without making any eſtate of it; he that firſt enters to hold that term out, is ſaid to acquire a property: and is called an occupant, by reaſon his title comes by the firſt occupation.

So if a tenant, for his own life, grant over his eſtate to another; if the grantee dies before him, there ſhall be an occupant.

OCCUPATION, or Occupancy, in the *Civil Law*, denotes the poſſeſſion of ſuch things as at preſent properly belong to no private perſon, but are capable of being made ſo. As, by ſeizing or taking ſpoils in war; by catching things wild by nature, as birds, and beaſts of game, &c.; or by finding things before undiſcovered, or loſt by their proper owners.

OCCUPATION is alſo uſed, in *Common Law*, for the putting a man out of his freehold in time of war.

Occupation amounts to the ſame with diſſeiſin in time of peace; only that the former is deemed not ſo great an offence. See DISSEISIN.

OCCUPATION is alſo uſed for holding tenure, or poſſeſſion. As, when we ſay, ſuch land is in the tenure or occupation of ſuch a man; that is, in his poſſeſſion.

OCCUPATIONS, in the ſtatutes De Bigamis, denote uſurpations upon the king, by uſing liberties or franchiſes a perſon is not entitled to.

As an unjuſt entry upon the king into lands and tenements is called an *intruſion*; ſo an unlawful uſing of franchiſes is called an *occupation*.

OCCUPATION-*Bridges* in a canal, are alſo called ſwing, ſwivel, or draw-bridges, and they are made for the private uſe of perſons whoſe lands adjoin the canal.

OCCUPAVIT, in *Law*, a writ which lies for him who is ejected out of his land, or tenement, in time of war; as a novel diſſeiſin lies for one ejected in time of peace.

OCCUPIERS *of Walling*, a term in the ſalt-works for the perſons who are the ſworn officers, that allot, in particular places, what quantity of ſalt is to be made, that the markets may not be over-ſtocked, and ſee that all is carried fairly and equally between the lord and tenant. Theſe perſons always appoint how many houſes ſhall work at a time; and when there is ſalt to be made, theſe appoint a cryer to proclaim it to all the workers, that they may put to their fires at the ſame time; and a like proclaiming of the time when they ſhall leave off; and thoſe who continue to work after this prohibition, are to have their ſalt ſpoiled or deſtroyed.

OCDA, in *Geography*, a town of Perſia, in the province of Irak; 150 miles E.S.E. of Iſpahan.

OCEAN, the vaſt collection of ſalt and navigable water which encompaſſes the whole globe of the earth.

The word comes from the Latin *oceanus*, of the Greek ωκεανος, which Euſtathius derives from ωκεως ναειν, *to ſlide ſwiftly*; others ſay, the Greeks borrowed it from the Phœnicians, who called the circumference of the ocean, *og*; from the Hebrew חוג, *hhog*, *circuit*, *ambit*.

The ocean is that huge body of waters, in which the two grand continents known to us, the new and old, are incloſed like iſlands.

By computation, it appears that the ocean takes up conſiderably more of what we know of the terreſtrial globe than the dry land: and recent diſcoveries have evinced that more than two-thirds of it are covered with water.

Dr. Keill computes the ſurface of the whole ocean to be 85490506 ſquare miles: ſo that ſuppoſing the depth of the ocean, at a medium, to be $\frac{1}{4}$th of a mile, the quantity of water in the whole will be 21372626$\frac{1}{2}$ cubic miles. See GLOBE, and *Magnitude of the* EARTH.

Yet Dr. Burnet computes that all the waters in the ocean were not ſufficient to drown or overflow the dry land ſo high as the ſcriptures ſay it was at the deluge: ſeven or eight oceans, according to him, would ſcarcely have ſufficed.

The ocean, penetrating the land at ſeveral ſtreights, or ſtraits, quits its name of ocean, and aſſumes that of *ſea*, or *gulf*; to which are uſually added ſome epithets, to diſtinguiſh it: as Mediterranean ſea, Perſian gulf, &c. In very narrow places it is called *ſtreights*, *ſinus*.

The ocean takes divers names, according to the divers countries on which it borders: as the Britiſh ocean, German ocean, &c. According to Maty, the ocean may be commodiouſly divided into *ſuperior*, or *upper*; and *inferior*, or *lower*.

OCEAN, *Upper*, which the ancients called the *exterior*, as environing all the known parts of the world, he ſubdivides, according to the four cardinal points, into the *northern*, *ſouthern*, *eaſtern*, and *weſtern*.

OCEAN, *Northern*, called alſo the *glacial*, *frozen*, and *Scythian*, is that part of the upper ocean next the north pole; bounded on the ſouth with the arctic circle, (hence called the *Arctic* ocean,) and the northern coaſts of Europe, Aſia, and America; and on the north with the unknown lands about the pole.

It is called the *icy* or *frozen* ocean, becauſe thoſe who have attempted a paſſage through it to China, &c. have always been ſtopped with the ice: and *Scythian* ocean, becauſe it waſhes the coaſts of Scythia. See FROZEN *Ocean*.

OCEAN, *Weſtern*, or *Atlantic*, is that part of the grand ocean which waſhes the weſtern coaſts of Europe and Africa, and the eaſtern of America, extending from the arctic circle to the equinoctial: or, more generally ſpeaking, is that which ſeparates the ancient continent from the new.

OCEAN, *Southern*, or *European*, is that part reaching from the equinoctial to the unknown antarctic lands. That part of this ocean which lies between the antarctic circle and the ſouthern pole is called the antarctic ocean, and is in fact only a continuation of the Pacific, Atlantic, and Indian oceans.

OCEAN, *Eaſtern*, or *Indian*, has its firſt name from its ſituation to the eaſt; and its latter from India, the chief country it waſhes. It reaches from the coaſt of Ajan to the Iſle aux Latrons, *i. e.* of *Thieves*.

It waſhes the ſhores of the eaſtern coaſt of Africa, and the ſouth of Aſia, and is bounded on the eaſt by the Indian iſlands, and the ſouthern continent.

OCEAN, *Inferior*, or *American*, is that vaſt part of the grand ocean, which waſhes the coaſt of America; unknown, in great meaſure at leaſt, to the ancients. It is divided into three parts, *viz.*

The *North ſea*, which waſhes the eaſtern coaſt of America, from the arctic circle to the tropic of Capricorn.

The *Magellanic ſea*, extending from the tropic of Capricorn to the Terra aſtralis incognita.

The *South ſea*, or *Pacific*, which waſhes the weſtern coaſts of America to the eaſt, as far as the iſle of Thieves; and from ſouth to north, from the tropic of Capricorn to the land of Jeſſo.

The *Pacific* ocean, in its whole extent, occupies nearly half the ſurface of the globe, from the eaſtern ſhores of New Holland to the weſtern coaſt of America. This ocean is diverſified with ſeveral groups of iſlands, which appear like the ſummits of vaſt mountains emerging from the waves. See PACIFIC *Ocean*.

OCEAN, *for the Saltneſs of the*, ſee SALTNESS.

OCEAN, *for the Tides obſerved in the*, ſee TIDES.

Phil. Sachſius, in 1664, printed a diſſertation, intitled "Oceanus Microcoſmicus," dedicated to Bartholine; wherein he ſhews that there is a circular motion in the waters, like that of the blood in the human body; that they all come from the ocean, and return thither again. The thought is Solomon's, Eccleſ. xii. See VAPOUR, SPRING, &c.

OCELLATI LAPIDES, in *Natural Hiſtory*, a name given by the ancients, ſometimes to expreſs certain ſtones found on the ſhores, and in the beds of rivers, and naturally marked with the figure of an eye; and ſometimes for ſmall round ſtones of the ſhape of the groove of the eye, made by art for children to play with, and of the nature of what

we call marbles. Suetonius tells us, that Auguſtus Cæſar uſed ſometimes to divert himſelf with playing *nucibus et ocellatis*.

The word *lapidibus* is underſtood after the laſt word, and the meaning of the author plainly is, that he played like a boy, with nuts and marbles. But we have abundant teſtimony among the ancient naturaliſts of the word having been uſed alſo as the name of the gem which we now call *oculus beli*, and all thoſe other ſtones of the agate, or other ſemipellucid kinds, which had the figure of an eye naturally impreſſed upon them, that is a round ſpot of a different colour, in the centre of a ſmall roundiſh ſtone. Theſe were ſcarce among the ancients, becauſe they had none but the true oculi beli, or ſuch ſtones as were of a particular ſpecies, and were found naturally of the ſhape and ſize of an eye; but we have them much more common, becauſe our jewellers, whenever they find a natural ſpot in an agate, ſurrounded with a white circle, cut it out from the reſt of the ſtone, and ſell it as a natural oculus beli.

OCELLUM, in *Ancient Geography*, a promontory of Britain, generally ſuppoſed to be Spurn-head; and Mr. Baxter, with great probability, thinks the name is derived from the Britiſh word Ochel (Uchel) lofty. There is a very lofty mountain in Scotland, called Ocelli-mons, Ochill-hills, for the ſame reaſon.

OCELLUS, in *Biography*, an ancient Greek philoſopher of the Pythagorean ſchool, was a native of Lucania, whence the ſurname of the *Lucanian* is commonly given to him. The time in which he flouriſhed was the age before Plato, which is inferred from a letter preſerved by Diogenes Laertius, in which Archytas informed Plato that he had received ſeveral pieces written by Ocellus, from his grandſons. Among theſe was a treatiſe "Of Laws, or Kings and Kingdoms," of which a few fragments only remain, which are preſerved by Stobæus. Another of his works was a book "On the Univerſe," which has come down to us entire; this has been ſuppoſed by Thomas Burnet to have been compiled from the writings of Ariſtotle, and he regarded it as an epitome of the Peripatetic doctrine concerning nature, but others pronounce it to have been in exiſtence long before the time of Ariſtotle, and that this philoſopher borrowed many things from Ocellus, but made uſe of them in a ſenſe very different from that of their original author. A ſummary of the doctrine taught by Ocellus is given by Dr. Enfield in his abridgment of Brucker, vol. i. to which we refer our readers. It is a ſpecimen of the Pythagorean doctrine, intermixed with tenets peculiar to the author. He maintained that the univerſe never had a beginning, nor will have an end; that the world, in its preſent beautiful form, is to be diſtinguiſhed from the univerſe of which it is formed; and that the collection of all beings which forms the world is itſelf perfect and entire, and has no connection with any thing extrinſic. The immutable eſſences of Ocellus are the ſame with the intelligible natures of Pythagoras (ſee PYTHAGOREAN *Syſtem*); and the doctrine of Ocellus concerning dæmons, that they inhabit the ſublunar regions, is eſſentially different from that of Ariſtotle, who ſuppoſed no ſuch intelligences, except in the celeſtial ſphere. The work of Ocellus here referred to, was firſt printed in Greek at Paris in 1539; and at Venice in Greek with a Latin verſion by Lewis Nogarola in 1559: it has ſince gone through many editions, of which the moſt valuable is ſaid to be that of Dr. Thomas Gale, with the verſion of Nogarola, and learned notes, in his "Opuſcula Mythologica," printed at Cambridge in 1671. Moreri. Enfield's Hiſt. Phil.

OCELOT of Buffon, in *Zoology*, called by others the *Mexican cat*, and by Hernandez *tlacooxelotl*, is a ſpecies of cat, or FELIS *Pardalis* of Linnæus; which ſee.

This animal inhabits Mexico, the neighbourhood of Carthagena, and Brazil; lives in the mountains; is very voracious, but fearful of mankind; preys on young calves, and different ſorts of game; lurks amidſt the leaves of trees; and ſometimes extends itſelf along the boughs, as if dead, till the monkies, approaching to examine it, become its prey. Pennant.

OCHAGAVIA, in *Geography*, a town of Navarre; 23 miles E. of Pamplona.

OCHAN, a town of Ruſſia, in the government of Perm, on the Kama; 20 miles S.S.W. of Perm. N. lat. 57° 28'. E. long. 54° 30'.

OCHEL, a river of Sileſia, which runs into the Oder; nine miles below Beuthen.

OCHIL HILLS, an extenſive range of mountains in Scotland, commence in the pariſh of Dumblane, Perthſhire, and paſſing through Clackmannanſhire, along the north bank of the river Forth, ſtretch for many miles into the county of Fife. Theſe hills riſe, for the moſt part, abruptly from the valley, on their ſouthern ſide, and in ſome places their aſcent is almoſt perpendicular. The whole ridge may be characteriſed as covered with green, to its higheſt ſummit. The more gentle ſlopes abound with villages, hamlets, and farmhouſes, ſometimes ſkirted by woods, and ſometimes entirely enveloped in their umbrageous ſhade. The higheſt hill of the Ochils is Bencleugh, which, according to Mr. Stobie, is 2450 feet in height. From the ſummit, the proſpect is extremely fine and extenſive, as no height intervenes even to the German ocean, and the country it overlooks is, in general, fertile and well cultivated. From ſome points the ſpectator has a moſt remarkable view of the Carſes of Stirling and Falkirk, with the river Forth meandering through them. On a peninſulated rock in the centre of a deep glen in this part of the ridge, provincially denominated the Alva-hills, ſtand the venerable ruins of Caſtle-Campbell, belonging to the family of Argyle. From its ſolitary and darkſome ſituation, this pile was called the Caſtle of Gloom; and all the names of the adjacent places were, and ſtill are, ſuitable, being ſeated in the pariſh of Dolor, waſhed by the ſtream of Sorrow, and enveloped by the glens of Care. It was deſtroyed in 1645 by the marquis of Montroſe, who carried fire and ſword through the whole eſtate, with ſuch inhuman cruelty, that he only left one houſe unconſumed, which he erroneouſly ſuppoſed to belong to a neighbouring baron. The caſtle was anciently ſupplied with water by means of a ſecret ſtair cut downwards through the ſolid rock to one of the adjoining rivulets. This paſſage is ſix feet wide, and from its ſituation, overhung with impending rocks and trees, is frightful even to look into. It is called by the inhabitants Kemp's ſcore, or cut, from having been formed, as tradition relates, by a perſon of that name, to whom the fortreſs is ſaid to have originally belonged.

The Ochil hills are compoſed of red and grey granite, whinſtone, and various kinds of ſchiſtus; and contain numerous veins of the more uſeful minerals. Some portions of them exhibit traces of a volcanic origin, great quantities of lava being diſcovered on their ſides, or lying in immenſe maſſes in the vale below. In the weſtern diviſion of theſe hills an attempt was made to work a ſilver mine, but after four years continuance the work was abandoned as unprofitable. This happened in 1761, but previous to that period a valuable ſtratum of the ſame metal was diſcovered in the glen that divides the Middle-hill from the Wood-hill, above the pariſh of Alva. It was firſt perceived in ſmall ſtrings of

ſilver

ſilver ore, which, being followed, conducted the workmen to a rich maſs of, what is commonly called, virgin ſilver. The produce of this vein was no leſs than twelve ounces of the pure metal from fourteen ounces of ore. The expence of the diſcovery did not exceed 50*l.*; and during fourteen weeks the quantity raiſed weekly amounted to more than 40,000*l.* ſterling in value. When this maſs, however, was exhauſted, the ſilver diſappeared, and lead and other minerals were found in its ſtead, upon which the ſearch was given up for many years. But being renewed in 1759, a pit was ſunk below the ſpot whence the rich collection of ore was extracted, when another maſs of metal was laid open, which was at firſt ſuppoſed to be ſilver, though, on further examination, it proved to be the ſemi-metal called cobalt, which is uſed in forming the blue glazings of china-ware, and in giving a blue colour to glaſs. The cobalt of Alva was tried at Preſton-Pans works, and found to be equal in quality to that with which Europe is, in general, ſupplied from the mines of Saxony. Unhappily, however, the maſs of this mineral, like that of the ſilver, was ſoon exhauſted, and though ſmall quantities of it have ſince been diſcovered in various parts of the Ochils, it has never again appeared in ſufficient abundance to render it an object of commerce. The other metals found on theſe hills are copper, lead, and iron. About fifty years ago a copper mine was wrought in what is called the Mill-Glen, by an Engliſh company. The thickeſt ſtratum or vein meaſured about 18 inches; and four different ſtrata were traced. Iron-ſtone is very abundant in the Clackmannan diſtrict, and, in conſequence, an extenſive iron-work has been eſtabliſhed in the vicinity of that town under the firm of the Devan company. The vale at the foot of the Ochils, on the ſouth ſide, may be regarded as one vaſt field of coal, which forms the moſt important article among the exports of this part of Scotland.

Mr. Charles Mackenzie has lately communicated to the "Wernerian Natural Hiſtory Society," a mineralogical deſcription of theſe hills. The rocks of which they are compoſed, arranged according to their ſituation and relative antiquity, the loweſt and oldeſt being the firſt mentioned, and the uppermoſt or neweſt being the laſt, are 1. Red ſand-ſtone; 2. Amygdaloid; 3. Grey ſand-ſtone; 4. Lime-ſtone; 5. Slate-clay; 6. Clay-ſtone; 7. Tuff; 8. Baſaltic clink-ſtone; 9. Green-ſtone; 10 Clay-ſtone porphyry; 11. Compact felſpar. The different veins that traverſe the ſtrata of the diſtrict of which this ingenious obſerver has given an account, are, calcareous ſpar, ſteatite, heavy ſpar, iron, cobalt, ſilver, copper, and lead. The firſt part of Mr. Mackenzie's communication contains a geographical delineation of this beautiful and intereſting range of hills. Beauties of Scotland, vols. iii. and iv. A Tour in Scotland, by Thomas Pennant, three vols. 4to. London 1790.

OCHINUS, Bernardin, in *Biography*, a celebrated Italian Capuchin monk, who flouriſhed in the ſixteenth century, and became a convert to the Proteſtant faith, was born at Sienna in the year 1487. While very young he entered among the religious of the Franciſcan order diſtinguiſhed by the name of Cordeliers, but reſuming the lay-habit, he applied himſelf to the ſtudy of phyſic, and acquired the eſteem of cardinal Julio de Medici, who afterwards aſcended the pontifical throne under the title of Clement VIII. He was now ſeized with compunction for having quitted the religious profeſſion, and re-entered the order which he had abandoned, and to which he became, as well by his talents as his piety, a bright ornament. In 1534 he entered the reformed order of Capuchins which had been lately confirmed, and in this new connection he diſtinguiſhed himſelf by his regularity, his auſterities, and ſanctity of demeanour. He contributed ſo much to extend and improve the order, that by ſome writers he has been deemed its founder. In 1538 he was elected vicar-general of the order, in a chapter which was held at Florence, and ſo well did he conduct himſelf, that he was, in 1541, elected a ſecond time to that dignity, in a chapter that was held at Naples. He became eminent in the higheſt degree as a pulpit orator, and was attended by crowds, not only of the common people, but of the moſt illuſtrious prelates, princes, and men of rank. So great was his fame as a preacher, that he was invited to diſplay his talents in the moſt celebrated cities of Italy; and he was choſen chaplain and father confeſſor to pope Paul III. About the year 1541 he became acquainted with John Valdes, a Spaniſh civilian, who had embraced the opinions of Luther, and by him Ochinus was converted to the ſame faith, and became ſatisfied that Popery was a ſyſtem of deluſion and tyranny over the conſciences of men, and that evangelical Chriſtianity was to be found only among the profeſſors of the reformed communion. This important change in his opinions was ſoon made known, and he was ſummoned to the court of Rome to anſwer for himſelf. In his journey he met with Peter Martyr, (ſee his article,) at Florence, who had likewiſe abandoned the Popiſh religion, and having conſulted together, they agreed to retire to ſome country where they might be beyond the reach of the papal power. Accordingly Ochinus immediately ſet out, and arrived at Geneva in the year 1542; from Geneva he went to Augſburg, where he publiſhed ſome ſermons. While in this place he married, and in 1547, on the invitation of Cranmer, archbiſhop of Canterbury, he accompanied Peter Martyr to England, for the purpoſe of carrying on the great work of reformation in this country. Here they met with a very cordial reception at Lambeth, and laboured with great diligence and ſucceſs in promoting the object of their miſſion. In the year 1549 John Poynet, afterwards biſhop of Wincheſter, publiſhed in Engliſh Ochinus's "Dialogue of the unjuſt uſurped Primacy of the Biſhop of Rome," which he had tranſlated from the Latin. According to Wood, Ochinus was made a prebendary of Canterbury; and Neal ſays that he and Fagius were ſo far patronized, as to have penſions or canonries with a diſpenſation of reſidence; but upon the death of king Edward VI. Peter Martyr and Ochinus were obliged to quit England. They returned to the continent, and arrived at Straſburg in the year 1553. In 1555 Ochinus went to Baſil, and accepted an invitation to become miniſter of an Italian church, which was formed about that time at Zurich. Here he continued to officiate till 1563, when, eſpouſing ſome doctrines not agreeable to the theological ſyſtem of the Helvetic doctors, he was obliged to reſign his charge, and he retired to Baſil, from which place he was alſo driven, at the age of 76, and compelled to ſeek a ſanctuary in an inclement ſeaſon of the year. He ſought refuge, but without ſucceſs, in Poland, an edict having been paſſed by king Sigiſmund, which baniſhed from his realms all heretics who were foreigners. Some of his friends would gladly have detained him in Poland, but he had learnt ſo much of the doctrine of paſſive obedience, as to declare that it was the duty of ſubjects to obey their ſovereign, and that he would ſet an example of obedience, and prefer death among the wild beaſts of the woods, than counteract his orders. He accordingly ſet out for Moravia, but was ſeized with the plague at Pinczow, which carried off two ſons and his daughter. Ochinus himſelf recovered ſo far as to be able to renew his journey, but he died in three weeks at Slawkaw, in 1564, about the age of ſeventy-ſeven. He was author of a vaſt number of works, written chiefly in Italian,

Italian, but they have been tranſlated into various languages: the moſt known are "A Commentary on the Epiſtle to the Galatians," and ſix volumes of ſermons.

OCHLOCRATIA, from οχλος, *multitude*, and κρατος, *power*, *command*, a form of government wherein the populace has the whole power and adminiſtration in its own hand.

OCHNA, in *Botany*, an old Greek name, whoſe etymology is very uncertain, retained by Linnæus for the preſent genus, in preference to a barbarous one, *Jabotapita*, which had been beſtowed, on what he ſuppoſed the ſame, by Plumier; (ſee GOMPHIA.) Whether Linnæus, in adopting *Ochna*, had any view in its derivation to the word αγχειν, *to ſuffocate*, on account of ſome of the germens being ſmall, or, as it were, abortive, can only be matter of conjecture, ſince he has left us no clue to warrant ſuch an aſſertion. Linn. Gen. 266. Fl. Zeylan. 93. Schreb. 354. app. 833. Willd. Sp. Pl. v. 2. 1158. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 297. Juſſ. 282. Lamarck Illuſtr. t. 472. f. 1.—Claſs and order, *Polyandria Monogynia*. Nat. Ord. *Coadunatæ*, Linn. *Magnoliæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five, ovate, or oblong, ſpreading, permanent leaves, as large as the petals. *Cor.* Petals from five to twelve, oblong, deciduous. *Stam.* Filaments numerous, ſhort, permanent; anthers linear, erect, deciduous. *Piſt.* Germens ſuperior, generally as many as there are petals; ſtyle awl-ſhaped, longer than the ſtamens, permanent; ſtigma perforated. *Peric.* Drupas ſeveral, elliptical, pulpy, placed in a circle. *Seed.* Nut ſolitary, the ſhape of the drupa, with one kernel.

Eſſ. Ch. Calyx five-leaved, inferior, permanent. Petals numerous, nearly equal. Drupas ſeveral. Nut ſolitary.

1. O. *ſquarroſa*. Yellow-flowered Ochna. Linn. Sp. Pl. 731. Roxb. Coromand. v. 1. 62. t. 89.—Stalks many-flowered. Petals eight. Native of the Eaſt Indies, and introduced at Kew, by ſir Joſeph Banks, in 1790, where it flowers in July and Auguſt.—This is a ſmall *tree*, with alternate *branches*. *Leaves* rather crowded at the ends of the branches, alternate, on ſhort ſtalks, oblong, acute, finely ſerrated, ſmooth, four or five inches long, and nearly half as broad, when young they are beautifully tinged with purple. *Flowers* in lateral, alternate *cluſters*, large, yellow, inodorous. *Bracteas* ſmall, deciduous. *Drupas* when ripe nearly black.

2. O. *parvifolia*. Small-leaved Ochna. Vahl. Symb. v. 1. 33. Willd. n. 2. (Euonymus inermis foliis alternis ovatis ſerrulatis; Forſk. Ægypt-Arab. 204.)—Stalks ſingle-flowered.—Native of Arabia Felix.—"The habit of this *ſhrub* greatly reſembles that of the laſt ſpecies, but its leaves and inflorescence are conſiderably ſmaller.—*Branches* round, ſmooth, covered with an aſh-coloured, dotted bark. *Leaves* alternate, on ſtalks, quite entire at the baſe, veined, ſhining, only half an inch long. *Flower-ſtalks* lateral, ſolitary, gradually thickening upwards, purple, longer than the leaf." *Vahl.*

OCHO RIOS, in *Geography*, a bay on the N. coaſt of the iſland of Jamaica. N lat. 18° 26'. W. long. 76° 56'.

OCHODONA, in *Zoology*. See LEPUS *Alpinus*.

OCHOTA, or OKHOTA, a river of Ruſſia, which runs into the ſea, at the town of Ochotſk.

OCHOTSK, or OKOTSK, a ſea-port town, or rather ſtation, of Ruſſia, which gives name to a province that is part of the government of Irkutſk, and from which veſſels ſail to Kamtſchatka. As the vicinity of this place produces little or no graſs, proviſions are brought hither from Yakutſk, both by land and water. Both modes of conveyance are difficult and tedious. The land carriage is by a road that lies over mountains, moraſſes, and through thick woods of larch and beech trees, and as the diſtance is 919 verſts, the journey with horſes and rein-deer takes up nearly ſix weeks. The latter are furniſhed for this purpoſe by the Tunguſians, who live in the neighbourhood of Ochotſk, near the ſea to which it gives name. N. lat. 59° 28'. E. long. 142° 44'.

This town is longer than it is wide, and extends from E. to W. nearly in a line. On the S. ſide is the ſea, at 100 yards from the houſes, with a beach of flints between. On the N. the walls are waſhed by the river Okhota, whoſe mouth is to the eaſtward, or at the extremity of a neck of land on which the town is built, and which widens towards the W. The buildings make but an indifferent appearance. Behind, cloſe to the river, is a ſtreet, inhabited by merchants, whoſe ſhops are regularly diſpoſed on each ſide. The port ſcarcely deſerves the name. M. de Leſſeps, when he viſited this place, counted ſeven or eight ſmall veſſels or galiots, ſome belonging to the crown, and others to merchants trading in furs to America. As Okotſk was the ſeat of government, and the principal mart for Ruſſian commerce, this inquiſitive traveller endeavoured to acquaint himſelf with the cauſes which firſt gave riſe to the enterpriſes of the Ruſſian colonies in that country, and which ſerved to fix them in it. He found, that by the conqueſt of the eaſtern part of Siberia, the Ruſſians got poſſeſſion of the rich mines with which they enriched themſelves, and which were held in little eſtimation by the inhabitants. To the extraction of iron, the conquerors added that of ſilver, of gold, and of other precious metals. The diſcovery of theſe ſources of wealth inflamed the courage of the adventurers, till the deſire of extending their dominions carried them to Irkutſk. At their firſt incurſions into the neighbouring countries, they perceived with regret that the ſame advantages were not to be expected. However, contemplating the clothing of the people, they were furniſhed with a new incentive to avarice, and determined to rob them of it; and on advancing further to the eaſt of Aſia, it was perceived that the furs became more beautiful; and hence the Ruſſians very eaſily perſuaded themſelves, that it would conduce to their intereſt and glory to ſubject every part of this vaſt territory to their laws. Accordingly they made themſelves maſters of the country as far as Okotſk, and puſhed their conqueſts in the north to the river Anadyr. Forts were conſtructed, and towns built. The Ruſſian merchants ſent their factors to Okotſk, which, from the advantages of its ſituation, became the metropolis. The navigation, however, was little more than cruiſing, and the veſſels from Kamtſchatka were chiefly galiots. The cargoes they brought back, that is, the precious ſtones taken from the inhabitants, either in barter or as impoſts, were ſent to the centre of the empire, and ſold under the direction of government, but without much profit, which was conſumed by the immenſe duties that were impoſed. In the mean time Okotſk flouriſhed, and the number of veſſels that entered its port daily increaſed as freſh connections opened freſh objects of traffick. The following is the mode of traffick adopted at Okotſk, whence ſeveral veſſels every year ſail for America. When a merchant wiſhes to make this voyage, he obtains permiſſion of the governor. The cargo is divided into ſhares, which are bought by thoſe who chooſe to become purchaſers. The price of the ſhares defrays the expence of fitting and of the different articles of merchandize, which conſiſt of ſtuffs, iron utenſils, glaſs trinkets, handkerchiefs, brandy, tobacco, and other commodities eſteemed by ſavages. The officers and ſailors have a part of the cargo inſtead of wages. Upon their return from a voyage, which laſts three, four, or ſix years, the owners

owners pay duties to the treaſury, and the remainder is valued and equally divided among the owners. A part of the merchandize is then ſent to Okotſk, and part to Yakutſk, thence to Irkutſk, and laſt of all to Kiachta, where the Chineſe become the purchaſers. Perouſe's Voyage, vol. ii. appendix.

OCHOTSK, or Okhotsk, *Mountains*, a great chain, known under the name of Stanovoi-Krebet, which borders upon the Nertſhinſkoi, or upon the Yablonoi-Krebet, near the region of the ſources of the Aldan and Oldekon, runs thence on one ſide northward on the Lena down to Yakutſk, and on the other ſide weſtward to the Oudinſkoi gulf of the Okhotſkoi ſea, which ſwarms with iſlands; proceeds round this to the Upper Okhotſk, and ſtrikes out ſeveral branches in the parts between the Lena and the Indighirka, between this and the Kolyma, and between this and the Anadyr, where a part of the mountain runs out upon the Tſhuſkoi promontory, while the other continues its courſe into the peninſula of Kamtſchatka. All theſe extenſive mountains are almoſt entirely unknown. From the diſtrict of Okhotſk have been brought jaſper, porphyry, and beautiful chalcedonies and carneoles, ſulphur-pyrites, native alum, agaricus aluminaris, mountain cryſtal, coals, &c.; and here are likewiſe warm ſprings. The mountain is, for the moſt part, not very abundant in woods. Its principal rivers on the Ruſſian or northern ſide are the Amga, the Aldan, the Uda, the Maia, the Yana, the Indighirka, the Kolyma, and the Anadyr.

OCHOTSKOE, or Okhotskoi, *Sea*, a large bay of the North Pacific ocean, on the E. coaſt of the Ruſſian dominions, ſo called from the ſea-port of Ochotſk, or Okhotſk. N. lat. 54° to 59°. E. long. 137° to 147°.

OCHRA, or *Gallinula* Ochra, in *Ornithology*, the name of a ſpecies of moor-hen. It is all over of a duſky and obſcure yellowiſh-green, and is browner on the breaſt and belly than on the back, yet with the ſame yellowiſh-green predominant; the head, neck, breaſt, and wings, have ſeveral white ſpots; and the face is in part white; the beak is part black, and part red; and the legs are of a yellowiſh colour. See Scolopax.

OCHRE, in the *Arts*, a yellow powder of an earthy appearance. It in general conſiſts of ſome earth, as lime or clay, combined with a ſub-ſalt or oxyd of iron.

The oxyd of iron in this ſubſtance is moſtly combined with either the ſulphuric or carbonic acids, and in general is derived from the decompoſition of ſuper-ſulphuret of iron. By expoſure to the air and moiſture, the latter ſubſtance is converted into ſulphuret of iron. This ſalt, by expoſure to the oxygen of the atmoſphere, ſoon reſolves itſelf into two ſalts, namely, the ſuper-oxyſulphat of iron and the ſub-oxyſulphat. The latter, being inſoluble, is precipitated, forming a yellow depoſit, frequently ſeen in ſuch chalybeate ſprings as reſult from the decompoſition of pyrites. This yellow precipitate penetrates the earth and tinges it with the ſame colour, but more dilute. The mixture conſtitutes a ſpecies of ochre. When the ſoil, with which the ſubſalt combines, conſiſts of certain proportions of lime and alumine, free from ſtones or other heterogeneous matter, the ochre is more valuable.

Thoſe chalybeate waters which contain the ſuper-carbonat of iron, and which are frequently found, are capable of forming ochre, but of a different quality from the laſt. The carbonat held in the water is ſuper-carbonat with the black oxyd of iron. By expoſure to the air an atom of carbonic acid eſcapes, the oxyd takes another atom of oxygen from the atmoſphere, and is precipitated with the other atom of carbonic acid in the form of oxycarbonat, which is in the form of an inſoluble powder of a yellow colour. This ochre is of a deeper yellow than that derived from the ſub-oxyſulphat. Its colour may be converted into a beautiful brown by applying a heat to it, ſufficient to expel its carbonic acid, leaving behind the ſecond oxyd of iron. The heat of boiling water is ſufficient for this purpoſe. This ochre, ſo changed, has moſt of the properties of umber. The ſub-ſulphat does not ſo readily aſſume the brown colour, on account of the greater heat required to expel its acid.

Artificial ochres may be prepared of equal, and perhaps of ſuperior quality to thoſe in nature. The ſulphat of iron in the manufacture of this article, previous to its cryſtallization, is partly in the ſtate of oxyſulphat, and becomes wholly ſo by long expoſure to the air. As it remains in this ſituation it will gradually reſolve itſelf into the ſuper-oxyſulphat and the ſub-oxyſulphat. The latter falls to the bottom of the veſſel in the form of a yellow powder, which, when waſhed and dried, conſtitutes a beautiful colour.

When carbonat of potaſh is added to the ſuper-oxyſulphat, the carbonat of iron will be formed, which will precipitate in the ſtate of a yellow powder. This powder, when waſhed, and the water evaporated, conſtitutes an ochre which is a little deeper in colour than the laſt. The heat of boiling water drives off the carbonic acid, leaving the oxyd of an agreeable brown colour.

Ochre, in *Agriculture*, a ſort of oxyd or calx of iron, which is frequently met with in ſome ſorts of ſoil. The author of Phytologia ſtates, that red ochre may in ſome caſes be favourable to vegetation, though it has generally been ſuppoſed prejudicial to it.

It is, however, ſtated by Mr. Nicol, that the moſt untoward of all ſoils, for the produce of timber in high perfection, is an irony till of little depth, lying on a retentive ſubſoil, which upholds a poiſonous ochry water, and which ſtagnates on the ſurface, or remains latent in the body of the ſoil, which is the paſture of the roots, contracting the mouths of the fibres, contaminating the juices, and finally operating to the deſtruction of the tree, by poiſoning it, and haſtening its diſſolution.

It is well known that ochres alſo form the baſis of various kinds of pigments, paints, and other ſimilar matters.

OCHREA, in *Botany*, Willd. Princip. of Bot. 50, a name given by Rottböll, to the peculiar kind of bractea, which enfolds the flower-ſtalks in *Cyperus*, and ſome ſimilar plants, in the form of a cloſe membranous ſheath. There ſeems little occaſion for this term, nor is it adviſable to give into the too general practice of botaniſts, who, in writing upon any one particular tribe or natural order, invent new terms without neceſſity. The terms *bractea*, *involucrum*, *receptacle*, &c. are univerſal, and we ſhould be involved in great confuſion if we had a ſeparate name for each in every different natural order. The cryptogamic authors are moſt prone to this inconvenient cuſtom, becauſe they fancy the plants with which they are converſant muſt, in every thing, differ from others.

OCHROITE of Klaproth, in *Mineralogy*, is the *Cerium* of the two Swediſh chemiſts, Hiſenger and Berzelius, and the *reddiſh* Tungsten of Scheele; which ſee.

OCHROMA, in *Botany*, ſo named by Profeſſor Swartz, from ωχρος, *pale*, in alluſion to the pallid hue of its flowers, leaves, and wool of its ſeeds. Swartz Prodr. 97. Ind. Occ. v. 2. 1143. Schreb. 454. Willd. Sp. Pl. v. 3. 605. Mart. Mill. Dict. v. 3.—Claſs and order, *Monadelphia Pentandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth double, inferior; outer of three, lanceolate, falling leaves; inner of one leaf, funnel-ſhaped, five-cleft. *Cor.* Petals five, wedge-ſhaped, coriaceous. *Stam.*

Stam. Filament one, cylindrical; anthers five, large, linear, connate, marked on the outſide with zigzag furrows. *Piſt.* Germen ſuperior, oblong; ſtyle thread-ſhaped, incloſed by the filament; ſtigmas five, awl-ſhaped, twiſted. *Peric.* Capſule coriaceous, ſomewhat cylindrical, angular, with five furrows, five cells, and five valves; valves internally woolly, revolute at the margin; partitions kidney-ſhaped. *Seeds* numerous, oblong.

Eſſ. Ch. Calyx double; outer of three leaves. Anthers combined, irregularly furrowed. Capſule five-celled, and many-ſeeded.

1. O. *Lagopus.* Down-tree. Swartz Prodr. 98. Act. Stockholm. for 1792. 148. t. 6. (Goſſipium; Plum. MSS. v. 4. t. 8. Goſſipium, ſeu Xylon arboreum; Pluk. Alm. t. 189. f. 2. Bombax pyramidale; Cavan. Diſſ. 5. t. 153. Hibiſcus arboreſcens, trichotomus; foliis ampliſſimis cordato-angulatis; feminibus lanâ obvolutis; Brown. Jam. 286.)—Found in waſte places on the hills of Jamaica and Hiſpaniola, where its beautiful flowers expand in February, and its capſules ripen in May. We think it flowered in great perfection, about two years ſince, in the ſtove of A. B. Lambert Eſq. V. P. L.S., at Boyton in Wiltſhire. The *trunk* of this *tree* is from twenty to forty feet in height, about twelve inches in diameter, erect, with a pale, aſh-coloured, brittle *bark*. *Branches* terminal, twice or thrice forked, ſpreading, ſmooth. *Leaves* more than a foot in length, terminal, nearly vertical, ſcattered, heart-ſhaped or roundiſh, angulated, ſmooth and dark-green above, pale underneath, with rufeſcent hairs. *Stalks* horizontal, as long again as the leaves, round, ruſty-coloured. *Flower-ſtalks* terminal, ſolitary, round, ſmooth, ſingle-flowered. *Flowers* erect, three or four inches long, pale red or yellowiſh, ſomewhat ſucculent and fleſhy. *Seeds* incloſed in a fine ruſty down.

The growth of this tree is ſaid to be very rapid, and its wood ſo light as to become a ſubſtitute for cork. The woollineſs of its ſeeds is particularly fine and ſilky, and is much uſed in the manufacture of fine hats.

OCHROPUS GALLINULA, in *Ornithology*, a name by which many authors have called a bird more uſually known by the name of tringa. See TRINGA *Ochropus*.

OCHROPUS, or *Gallinula Ochropus*, the yellow-legged moor-hen, a ſpecies of the gallinula, or moor-hen. It is of the ſize of the common kind; its beak, as well as its legs, is yellow, or of a ſulphur colour; its back is of a reddiſh-brown, the tips of its wings of a very fine red; it has white variegations on its head, and in the middle of its wings, and on its belly; the longeſt feathers of its wings are black; and there are alſo ſpots of black on the back in ſeveral places; the edges of its eye-brows are of a deep ſaffron-colour; and it has, beſide all theſe colours, a great deal of grey in the wings; it has no hinder toe. It builds in thickets, in watery places, among ruſhes and high graſs. See FULICA *Flavipes*.

OCHROSIA, in *Botany*, ſo called by Juſſieu, from ὠχρος, *pale*. Juſſ. 145. A ſhrub found by Commerſon in the iſle of Bourbon, where it is known by the name of Bois jaune, or Yellow wood. The *leaves* are three or four in a whorl. *Flowers* in axillary or terminal forked corymbs. *Calyx* minute, five-toothed. *Corolla* tubular, funnel-ſhaped; its limb in five deep ſpreading ſegments. *Style* one; *ſtigma* tumid. *Follicles* divaricated, drupaceous, ovate, each with a bilocular nut, with two or three kernels in each cell. *Seeds* unequal, flat, ſcarcely membranous at the ſummit.

Juſſieu refers this genus to his *Apocineæ*, before *Tabernæmontana*, to which and to *Rauwolfia* he eſteems it nearly allied.

OCHROXYLUM, a genus known only from Schreber, who had originally called it *Curtiſia*, in commemoration of the well-known botaniſt of that name, but upon finding the ſame honour had previouſly been conferred on Mr. Curtis, in the *Hortus Kewenſis*, Schreber changed the name to *Ochroxylum*, derived we preſume from ὠχρον ξυλον, *pale wood*. Schreb. app. 826. Mart. Mill. Dict. v. 3.—Claſs and order, *Pentandria Trigynia*. Nat. Ord. *Dumoſæ*, Linn. *Rhamni*, Juſſ.

Gen. Ch. *Cal.* Perianth very ſmall, permanent, divided into five, ovate, acute, ſpreading ſegments. *Cor.* Petals five, ovate, reflexed, rather obtuſe, excavated below the top, thickiſh, with a thinner margin. Nectary an annular, ſomewhat three-lobed, fleſhy gland. *Stam.* Filaments five, awl-ſhaped, flattiſh in the lower part, erect, a little longer than the corolla; anthers roundiſh, incumbent. *Piſt.* Germens three, placed on the nectary, boat-ſhaped externally; ſtyles ſhort; ſtigmas ſimple. *Peric.* Capſules? three, approximating, nearly globular, inwardly compreſſed, inſident on the lobes of the enlarged nectary, of one cell, burſting inwardly? *Seeds* two, convex on one ſide, compreſſed and angular on the other.

Eſſ. Ch. Calyx five-cleft. Petals five. Nectary an annular, three-lobed gland. Capſules? three, approximating, one-celled, two-ſeeded.

We are not aware that Schreber ever publiſhed an account of the ſpecies of *Ochroxylum*, neither is any thing known concerning it but what we find in his Genera above.

OCHRUS. See PISUM.

OCHSENBERG, in *Geography*, a town of Wurtemberg; 12 miles W. of Heilbronn.

OCHSENFURT, a town of the duchy of Wurzburg; 8 miles S.S.E. of Wurzburg. N. lat. 49° 4′. E. long. 20° 6′.

OCHSENHAUSEN, a town of Germany, near which is a princely abbey, founded as a priory in the year 1190, and raiſed to an abbey in 1391; 14 miles S. of Ulm.

OCHSENWERDER, an iſland in the Elbe, about eight miles long, and four wide, on which are ſeveral villages; 4 miles S.E. of Hamburg.

OCHTEE, a river which runs into the Weſer, about eight miles below Bremen.

OCHTROP, a town of Germany, in the biſhopric of Munſter; 21 miles N.N.W. of Munſter.

OCIER, a town of the iſland of Sardinia; 28 miles E.S.E. of Saſſari.

OCIMUM, in *Botany*, Sweet Baſil, ὠκιμον of the Greeks, has been ſuppoſed to owe its name to the ſtrong ſcent, for which ſeveral ſpecies of this genus are remarkable; but that ſcent is of too ſweet and aromatic a quality, and too famous on that account, to accord with the true meaning of the verb ὀζω. Some derive the word from ὠκεως, *quickly*, and ſuppoſe it alludes to the rapid germination or growth of the plant; a property which others rather attribute to a kind of fodder, termed *Ocymum*, diſtinct from *Ocimum*. Hence it appears that nothing certain is known on the ſubject. Linn. Gen. 300. Schreb. 396. Willd. Sp. Pl. v. 3. 158. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 422. Juſſ. 116. Lamarck Illuſtr. t. 514.—Claſs and order, *Didynamia Gymnoſpermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, two-lipped, very ſhort, permanent; upper lip flat, roundiſh, broadeſt, aſcending; lower in four acute cloſe ſegments. *Cor.* of one petal, ringent, reverſed; tube very ſhort, ſwelling upwards; one lip, which is turned uppermoſt, broadeſt, divided half way down into four obtuſe equal ſegments; the

other, directed downwards, narrower, longer, undivided, ſerrated. *Stam.* Filaments four, declining, two of them rather the longeſt, and two furniſhed with each a lateral reflexed proceſs at the baſe; anthers creſcent-ſhaped. *Piſt.* Germen in four deep lobes; ſtyle thread-ſhaped, the length and poſition of the ſtamens; ſtigma cloven. *Peric.* none, except the cloſed calyx. *Seeds* four, ovate.

Eſſ. Ch. Upper lip of the calyx orbicular; lower four-cleft. Corolla reverſed; one lip four-cleft; the other undivided. Outermoſt ſtamens furniſhed with a proceſs at their baſe.

This genus conſiſts of a number of generally herbaceous, and annual or biennial, plants, with oppoſite, ſimple, ſtalked *leaves*, and racemoſe whorled *flowers*, whoſe *corolla* is pale or purpliſh, ſometimes ſpotted. They are for the moſt part of Eaſt Indian origin, and valued for their peculiarly fragrant ſmell, which in ſome inſtances reſembles that of the nutmeg. Whether for this reaſon, or for any other, ſeveral of the ſpecies are held in ſuperſtitious veneration by the Hindoos, and are uſed in their religious ceremonies. Twenty-one ſpecies are enumerated in the 14th edition of Syſt. Veg., but in theſe are included the genus PLECTRANTHUS of L'Heritier. (See that article.) Willdenow has twenty-ſeven, of which thirteen are mentioned in Hort. Kew., as cultivated in the Engliſh gardens; where they generally require to be kept in the ſtove or green-houſe, or raiſed on a hot-bed and afterwards planted out in the borders, under the protection of a wall. They have little but their ſcent to recommend them, nor do they all poſſeſs this claim to notice. We ſuſpect that ſeveral nondeſcript ſpecies are ſtill latent, amongſt the unexplored weeds of India, and that ſome of thoſe already deſcribed are not very correctly determined. We regret our inability to clear up theſe doubts. Seeds of ſome of the more celebrated kinds, ſent by our learned friend Dr. Buchanan for the purpoſe of inveſtigation, unfortunately failed to vegetate. The ſpecies moſt in eſtimation are known at Calcutta by the general appellation of Toolſey. The following may ſerve as examples.

O. *gratiſſimum.* Shrubby Baſil. Linn. Sp. Pl. 832. Willd. n. 5. Ait. n. 3. Jacq. Ic. Rar. t. 495. (O. zeylanicum perenne odoratiſſimum latifolium; Burm. Zeyl. 174. t. 80. f. 1.)—Stem ſhrubby. Leaves ovate. Cluſters cylindrical.—Native of Ceylon and other parts of the Eaſt Indies. Miller cultivated it in 1752. This is one of the few ſpecies whoſe *ſtem* is ſhrubby, forming a buſh two or three feet high. The *leaves* are ſtalked, truly ovate, though tapering at the baſe, and copiouſly ſerrated, two or three inches long, ſlightly downy, eſpecially on the ribs and veins; their ſmell, when gently touched, like cloves or nutmegs. *Flowers* very numerous, ſmall, downy, reddiſh, in long copious terminal, ſpreading, ſtraight cluſters.

O. *Baſilicum.* Common Sweet Baſil. Linn. Sp. Pl. 833. Willd. n. 9. Ait. n. 5. (Ocimum; Camer. Epit. 308. O. magnum; Ger. em. 673.)—Leaves ovate, ſmooth. Calyx fringed.—Native of India and Perſia. One of the exotics firſt known in our gardens. It may be treated as a hardy annual, but is beſt raiſed on a hot-bed. The *leaves* are peculiarly ſmooth, ſoft, and cool to the touch, and if not too much bruiſed, exhale a very delightful ſmell. They vary in colour, being often ſpotted with purple, and are alſo occaſionally curled, cut, or bliſtered. The very hairy *calyx* is remarkable.

O. *ſanctum.* Purple-ſtalked, or Sacred Baſil. Linn. Mant. 85. Willd. n. 12. Ait. n. 7. (Kattu-tumba; Rheede Hort. Malab. v. 10. 183. t. 92.)—Leaves rather oblong, blunt, ſerrated, wavy. Stem hairy. Bracteas heart-ſhaped.—Native of the Eaſt Indies. Said to have been introduced into this country by the late Duke of Northumberland in 1758. It is annual, and kept in the ſtove. Linnæus had an Eaſt Indian ſpecimen ſent him, as the "Sacred herb of the Bramins;" as well as ſeeds, which he raiſed at Upſal. He juſtly remarked that the herb has ſcarcely any ſmell. Dr. Buchanan thinks there is ſome error in the hiſtory of this ſpecies, the Baſil, which is really held ſacred, having a powerful odour.

O. *americanum* appears likewiſe to be involved in ſome obſcurity; that of Linn. Sp. Pl. 833, ſaid to come from America, being a much ſmaller and narrower-leaved plant than Jacquin's, Hort. Vind. v. 3. 45. t. 86, which laſt was marked by Linnæus *purpuraſcens*, but he does not appear to have deſcribed it under that name. He had a Jamaica ſpecimen from Browne.

OCIMUM, in *Gardening*, comprehends plants of the tender herbaceous aromatic annual kind, of which the ſpecies cultivated are; the common ſweet baſil (O. baſilicum); the buſh baſil (O. minimum); and the ſlender-ſpiked baſil (O. tenuiflorum).

The firſt has varieties with purple fringe-leaves; with green fringe-leaves; green with ſtudded leaves; and the large-leaved baſil.

But the middle-ſized variety, or that which is uſed in the kitchen, eſpecially in French cookery, riſes about ten inches high, ſending out oppoſite, four-cornered branches from the very bottom: the leaves are ovate-lanceolate, ending in acute points, indented on their edges. The whole plant is hairy, and has a ſtrong ſcent of cloves, which to ſome is very agreeable.

The chief ſubvarieties of which are; the common baſil, with very dark green leaves, and violet-coloured flowers; the curled-leaved baſil, with ſhort ſpikes of flowers; the narrow-leaved baſil, ſmelling like fennel; the middle baſil, with a ſcent of citron; the baſil with ſtudded leaves; and baſil with leaves of three colours.

In the ſecond ſort there are alſo varieties with black purple leaves, and with variable leaves.

Method of Culture.—Theſe are all capable of being increaſed by ſowing the freſh ſeeds in the latter end of March, upon a moderate hot-bed, covered to the depth of five or ſix inches with good light mould, putting them in a quarter of an inch deep, freſh air being given daily, and ſlight waterings occaſionally. When the plants have attained a few inches in growth, they ſhould be pricked out upon another hot-bed four inches apart, or ſet in pots of a ſmall ſize, plunging them in the hot-bed, water and occaſional ſhade being given till freſh rooted, with freſh air and water in ſmall proportions afterwards. In the latter part of the ſpring or beginning of ſummer, they ſhould be begun to be hardened, and in the hot weather ſet out in the open air where wanted. Some may be ſet out in the borders in the open ground, a ſlight watering being given at the time.

But in order to obtain good ſeeds, a few of the potted plants ſhould be placed in a good green-houſe, or glaſs caſe, in the latter end of the ſummer, freſh air being freely admitted.

It may be obſerved that the firſt ſort and varieties are often uſed as culinary herbs, and all the ſorts may be ſet out among other potted plants, in rooms and windows, eſpecially the buſh ſort, as well as in the borders and clumps for ornament and variety.

OCIVAS, in *Geography*, a town of Brazil, in the government of Maranhao.

OCKENHEIM, or HOKENHEIM, in *Biography*, the oldeſt and moſt venerable compoſer in parts on the conti-

nent, of whoſe works we have been able to find any remains.

M. le Duchat, in his notes upon Rabelais, ſays he was a native of Hainault, and treaſurer of St. Martin de Tours; but we believe this aſſertion was hazarded more with the patriotic view of making Okenheim as much a Frenchman as poſſible, than from proof or conviction; for he was always ſpoken of as a Netherlander by his contemporaries, Tinctor, Franchinus, and even in the "Deploration," or Dirge, written upon his death, which his ſcholar, Juſquin, ſet to muſic in five parts, as well as in the following, which was ſet by Guillaume Creſpel:

"Agricola, Verbonnet, Prioris,
Joſquin des Pres, Gaſpard, Brunel, Compere,
Ne parlez plus de joyeulx chants, ne ris,
Mais compoſez un *ne recorderis*,
Pour lamenter noſtre maiſtre et bon pere."

There is ſtill another dirge, in Latin, on the death of Okenheim, ſet to muſic by Lupi, a Netherlander, and compoſer of eminence in the time of the emperor Charles V. Many of whoſe Latin motets, and French ſongs, in parts, are preſerved in the muſeum collections, as are thoſe of Creſpel, the compoſer of the French "Deploration," juſt cited.

Little more is recorded concerning the life of Okenheim; than that he was a Netherlander, who flouriſhed in the fifteenth century, produced many learned and elaborate compoſitions for the church, and had many ſcholars, by whom he ſeems to have been much beloved and reſpected. It is, indeed, often mentioned to his honour, that he was the maſter of Juſquin: but he ſeems to have been as fortunate in a diſciple, as Juſquin in a maſter: as no great profeſſor is ſure of making great ſcholars in any art, unleſs he have genius and diligence to direct; and it is only from ſuch fortunate and rare concurrences that the narrow limits of mediocrity are ſurpaſſed, or the wild effuſions of youthful ardour reſtrained.

None of the muſical writers of the ſixteenth century forget to tell us that Okenheim compoſed a motet in thirty-ſix parts: of what theſe parts conſiſted, or how they were diſpoſed, is not related by Ornithoparcus, Glareanus, Zarlino, or any one who mentions the circumſtance, which all ſeem to have received from tradition. But of our countryman, Bird, a ſong is ſtill preſerved in forty parts; yet though we have ſeen this effort of ſcience and labour, the effects muſt ſtill be left to imagination, for where ſhall we find forty voices, aſſembled together, that are able to perform it.

We may, however, deduct from the reputation of Okenheim all the increaſe it received from the ſtory of his Polyphonic compoſition, and there will ſtill remain ſufficient cauſe for the reſpect and wonder of contrapuntiſts, in the fragments only of his works which have been preſerved in the "Dodecachordon" of Glareanus. This writer tells us, that he was fond of the Καθολικα in the cantus; that is, of compoſing a melody which may be ſung in various modes, or keys, at the pleaſure of the performer, obſerving only the ratio or relation of conſonant notes in the harmony.

Okenheim likewiſe compoſed a maſs for three and four voices, *ad omnem tonum*, which, as the words imply, might be ſung in any of the three ſpecies of diateſſaron, each part beginning at *ut*, *re*, *mi*, or in *c*, *f*, *g*, major, and *d*, *e*, *a*, minor, on which account no indicial clef is marked; as the performer, at ſetting off, has his choice of any of the modes, or eccleſiaſtical keys. Indeed all the fragments from Okenheim are inſerted in Glareanus, without bars, clefs, or accidental flats and ſharps.

It is not certain when Okenheim died, but he is generally mentioned as a compoſer of the fifteenth century, and we have met with no proof of his exiſting in the next.

OCKER, in *Geography*, a river which riſes by ſeveral ſprings in the Hartz foreſt, about 8 miles S.E. from Goſlar, and after paſſing by Wolfenbuttle, Brunſwick, &c. runs into the Aller, 5 miles W. of Gifhorn.

OCKLEY, Simon, in *Biography*, a diſtinguiſhed oriental ſcholar, was born at Exeter in 1678. He was entered of Queen's college, Cambridge, in 1696, where he applied himſelf very aſſiduouſly to the ſeveral branches of literature, and eſpecially to the oriental languages. Having taken orders, he was preſented to the living of Swaveſey, in Cambridgeſhire, and in 1711 was choſen profeſſor of Arabic in that univerſity. He married while young, and the expences of a growing family involved him in debt, for which he was thrown into confinement among the debtors in Cambridge caſtle, whence he dates one of his works in the year 1717. It is not known by what means he obtained his liberty, but he did not live long to enjoy it, dying in 1720. He diſplayed his zeal for promoting the ſtudy of Eaſtern literature, in a publication entitled "Introductio ad Linguas Orientales," dedicated to the biſhop of Ely, and addreſſed to academical youth, with an exhortation to purſue a branch of learning, without which, he ſays, no one ever became a great divine. The moſt conſiderable work of this learned author was his "Hiſtory of the Saracens," from 632 to 705, in two volumes octavo; the firſt was publiſhed in 1708, and the ſecond in 1718, while he was in priſon. This is a valuable work, and contains much curious and entertaining information, reſpecting the religion, manners and cuſtoms of the Saracens, of which a great part was new at the time when he wrote. In 1707 he publiſhed a tranſlation from the Italian of "The Hiſtory of the Preſent Jews throughout the World by Leo Modena, a Venetian Rabbi;" and in the following year he gave a tranſlation from a curious work entitled "The Improvement of Human Reaſon, exhibited in the Life of Hai Ebn Yokdhan, written by Abu Jaafar Ebn Tophail." Biog. Brit.

OCLISSER, in *Geography*, a town of Hindooſtan, in Guzerat, on the S. ſide of the Nerbuddah, oppoſite to Baroach.

OCOCOLIN, in *Ornithology*. See Tetrao *Nævius*.

OCOL, in *Geography*, a town of Thibet; 80 miles W.N.W. of Cha-tcheou.

OCONA, a town and port of Peru, near the coaſt of the Pacific ocean, in the dioceſe of Arequipa; 96 miles W.N.W. of Arequipa. S. lat. 16°.

OCONEE, a river of America, which is the N. main branch of Alatamaha river, in the ſtate of Georgia, in many places 250 yards wide; its banks abound with oak, aſh, mulberry, hickory, black walnut, elm, ſaſſafras, &c.—Alſo, a town on the E. bank of the fore-mentioned river; 62 miles W. by N. from Auguſta.

OCOPA, a town of Peru, in the juriſdiction of Atun Xauxa.

OCOQUAN, a river of America, in Virginia, which, after a ſhort courſe, diſcharges itſelf into Patowmack river, five miles below Colcheſter, N. lat. 39° 39'. W. long. 77° 18'.

OCORONI, a town of New Mexico, in the province of Cinaloa; 12 miles N. of Cinaloa.

OCOTEA, in *Botany*, a name of Aublet's, of whoſe origin or meaning we have no account. It can ſcarcely have been

been manufactured out of *Ajou-hou-ha*, the Caribean appellation of the fine tree to which it belongs. See POROSTEMA.

OCOTZINITZAN, in *Ornithology*. See ORIOLUS *Annulatus*.

OCOZINGO, in *Geography*, a town of Mexico, in the province of Chiapa; 40 miles E. of Chiapa dos Eſpagnols.

OCREA, among the *Ancients*, a kind of military ſhoe, or ſhort boot, which was made of white tin, and ornamented with gold or ſilver, about the ankles. Its uſe was very ancient; the Greeks were ſo well provided with them in Homer's time, that he thence gives them the appellation of ἐυκνημιδες Αχαιοι. Among the Romans, none were allowed to wear the *ocreæ*, but the two upper claſſes of the people, or ſuch whoſe eſtate exceeded 7500 drachmas.

OCRECOCK INLET, in *Geography*, a navigable inlet, though dangerous without a pilot, on account of its bars and ſhoals of ſand, on the coaſt of North Carolina, leading into Pamlico ſound, and out of it into Albemarle ſound, through which all veſſels muſt paſs that are bound to Edenton, Waſhington, Bath, or Newbern. N. lat. 35° 10'.

OCRIDA. See AKRIDA.

OCRINUM, in *Ancient Geography*, a promontory of the iſle of Albion, which was undoubtedly the Lizard point in Cornwall, probably called Ocrinum, from Och Rhen, a high promontory; and as the Britons kept poſſeſſion of Cornwall ſo long, we need not be ſurpriſed that the preſent name of that promontory, the Lizard, is alſo of Britiſh derivation, from Lis-ard, a lofty projection.

OCROPHUS, in *Ornithology*. See TRINGA *Ochropus*.

OCRZKA, in *Geography*, a town of Poland, in the palatinate of Lublin; 26 miles N.W. of Lublin.

OCTABIS, in *Law*. See OCTAVE.

OCTACHORD, an inſtrument or ſyſtem of muſic, compoſed of eight ſounds, or ſeven degrees. The *octochord*, or lyre of Pythagoras, comprehended the eight ſounds expreſſed by theſe letters, E, F, G, a, b, c, d, e: that is to ſay, two disjunct tetrachords.

OCTAETERIDES, formed from οκταετηρις, compoſed of οκτω, *eight*, and ετος, *year*, in *Chronology*, &c. the ſpace or duration of eight years.

OCTAETERIS, οκταετηρις, in *Antiquity*, a cycle, or term of eight years, at the end of which three entire lunar months were added. This cycle was in uſe till Meton, the Athenian, reformed the calendar, by finding out the golden number, or cycle of nineteeen years. See CALENDAR and CYCLE.

OCTAETIS, in *Natural Hiſtory*, a name given by Linnæus, and many other authors, to a kind of ſtar-fiſh of the aſtrophyte claſs, the rays of which are eight in number, where they firſt part from the body, but ſoon divide into many more.

OCTAGON. See OCTOGON.

OCTAHEDRON, or OCTAEDRON, in *Geometry*, one of the five regular bodies; conſiſting of eight equal and equilateral triangles.

The octahedron may be conceived as conſiſting of two quadrilateral pyramids put together at their baſes.

Its ſolidity, therefore, is had, by multiplying the quadrangular baſe of either by one-third of the perpendicular height of one of them, and then doubling the product. The ſquare of the ſide of an octahedron is in a ſubduple ratio of the ſquare of the diameter of the circumſcribing ſphere. See REGULAR *Body*.

OCTANDRIA, in *Botany*, the eighth claſs in the Linnæan artificial ſyſtem, and ſo named from the flowers which belong to it having eight ſtamens, in the ſame flower with the piſtil or piſtils. The orders are four: 1. *Monogynia*, a very various and rich one, containing *Epilobium*, *Fuchſia*, *Erica*, *Vaccinium*, *Daphne*, and ſeveral other intereſting plants. 2. *Digynia*, a very ſmall order; ſee MOEHRINGIA. 3. *Trigynia*, chiefly remarkable for *Polygonum*, which however is not conſtant in the number of either ſtamens or ſtyles. 4. *Tetragynia*, in which we find two curious Britiſh plants, the *Paris* and *Adoxa*.

OCTANT, or OCTILE, in *Aſtronomy*, an aſpect or poſition of two planets, &c. wherein their places are diſtant by an eighth part of a circle, or 45 degrees from one another. See ASPECT.

OCTAPLA, formed from οκτω, *eight*, q. d. *ſomething with eight rows* or *columns*, a term in the ſacred learning, uſed for a kind of ancient Polyglot bible, conſiſting of eight columns.

In the firſt column was the Hebrew text, in Hebrew characters; in the ſecond, the ſame text in Greek characters; in the third, the Greek verſion of Aquila; in the fourth, that of Symmachus; in the fifth, the Septuagint; in the ſixth, that of Theodotion; in the ſeventh, that called the *fifth*; the laſt was that called the *ſixth*.

Origen was the author of the octapla, as well as of the tetrapla and hexapla.

OCTARARO CREEK, in *Geography*, a river of America, in Pennſylvania, which runs into the Suſquehanna, N. lat. 39° 40'. W. long. 76° 12'.

OCTATEUCH, in the *Sacred Literature*, is uſed for the eight firſt books of the Old Teſtament, *viz.* Geneſis, Exodus, Leviticus, Numbers, Deuteronomy, Joſhua, Judges, and Ruth. Procopius of Gaza has ten commentaries on the Octateuch.

OCTAVE, the firſt and moſt perfect of concords in *Muſic*, in the order of their being generated by the harmonies of a ſingle ſtring; after the uniſon, it is that among all the ſounds of which the ratio is moſt ſimple. The uniſon is in the ratio of equality, the coincidence of the pulſations happening together; that is, as 1 to 1. The octave is in the double ratio, that is, as 1 to 2. The harmonies of the two ſounds reciprocally agree without exception, which does not happen in any other interval. In ſhort, theſe two ſounds (uniſon and octave) have ſuch an affinity and reſemblance, that they are often confounded in the melody, and in the harmony even one is indifferently taken for the other. When a child or a woman ſeems to be ſinging in uniſon with a man, they are conſtantly ſinging in octaves. This interval is called octave, or eighth, becauſe in aſcending diatonically there are ſeven degrees and eight different ſounds. The following are the properties which ſo ſingularly diſtinguiſh the octave from all other intervals.

I. The octave includes within its limits all the primitive and original ſounds; ſo that after having eſtabliſhed a ſyſtem or ſeries of ſounds in the extent of the octave, if we continue the progreſſion, it muſt be done in a ſecond octave by a ſimilar ſeries, and of a ſecond and third or more octaves, where no ſound will occur, which is not a recurrence of ſome one of the firſt ſeries; and ſuch a ſeries is called the ſcale of muſic in the firſt octave, and replicates or recurrences in all the reſt. (See SCALE and REPLICATE.) It is by virtue of this property of the octave, that it has been called *diapaſon* by the Greeks. See DIAPASON.

II. The octave further embraces all the conſonances and all their differences, that is, all the ſimple concords and diſcords, and, conſequently, all harmony. If we eſtabliſh all the conſonances upon the ſame fundamental ſound, we ſhall have the following table:

120 100 96 90 80 75 72 60
120 120 120 120 120 120 120 120

which amounts to this:

I. $\frac{5}{6}$ $\frac{4}{5}$ $\frac{3}{4}$ $\frac{2}{3}$ $\frac{5}{8}$ $\frac{3}{6}$ $\frac{1}{2}$,

where all the concords are found in the following order: the third minor, the third major, the fourth, the fifth, the ſixth minor, the ſixth major, and laſtly, the octave.

By this table it is manifeſt, that the ſimple concords are all contained between the octave and uniſon. They may even be heard all at once in the compaſs of an octave without any mixture of diſcords. Strike at the ſame time theſe four ſounds, C E G c, in mounting from the loweſt ſound to its octave, and they will form all the concords, except the major ſixth, which is compounded; and will form no other interval. Take any two of theſe ſounds you pleaſe, and the interval will be always conſonant. It is from this union of all the concords, that the chord which they produce is called the *common* or *perfect chord*.

The octave giving all the concords, conſequently gives all the ſhades or differences, and by that means all the ſimple intervals of our muſical ſyſtem; which arè but deviations. The difference of the third major and the third minor gives the minor ſemitone; the difference of the third major and the fourth, the major ſemitone; the difference of the fourth and fifth gives the tone major; and the difference of the fifth and ſixth major gives the minor tone. Now the ſemitone minor and the ſemitone major, the tone minor and the tone major, are the only elements of all the intervals of muſic.

III. Every conſonant ſound with one of the terms of the octave, is conſonant alſo with the other; conſequently, every diſſonant ſound with one is diſſonant with the other.

IV. Finally, the octave has ſtill this property, the moſt ſingular of all, that it may be doubled, tripled, and multiplied at pleaſure, without changing its nature, and without ceaſing to be a perfect concord.

This multiplication of the octave, as well as its diviſion, is however bounded with reſpect to the powers of our organ of hearing; and an interval of eight octaves exceeds our appreciation. (See COMPASS.) The octaves even loſe ſomething of their ſweetneſs, by being multiplied; and when a certain meaſure is paſſed, all the intervals become leſs eaſy for the ear to ſeize; a double octave even becomes leſs agreeable than a ſingle; a triple than a double: in ſhort, at the fifth octave, the extreme diſtance of the ſounds robs conſonance of almoſt all its charms. It is from the octave that we draw the order of all intervals by harmonic diviſions and ſubdiviſions. Divide the octave harmonically 3 6 by the number 4, and you will have on one ſide the fourth 3 4, and on the other the fifth 4 6. Divide in the ſame manner the fifth 10 15 harmonically, by the number 12, and you will have the minor third 10 12, and the major third 12 15. Laſtly, divide the major third 72 90, and the tone major 80 90, or 8 9, &c. It ſhould be remembered, that theſe harmonical diviſions give two unequal intervals, of which the leaſt is the grave and the greateſt the acute. That if we make the ſame diviſions in arithmetic proportion, we ſhall have the ſmalleſt interval in the acute and the greateſt in the grave. Thus the octave 2 4, divided arithmetically, will firſt give the fifth 2 3 in the grave, then the fourth 3 to 4 in the acute. The fifth 4 6 will firſt give the major third 4 5; then the minor third 5 6, and ſo on. We ſhall have the ſame ratios in a contrary ſenſe, if, inſtead of taking them as we have juſt done, by the vibrations, we ſhould calculate from the length of the ſtrings. Theſe diſcoveries, indeed, are of little uſe in themſelves on keyed inſtruments, but they are neceſſary to the peruſal of old authors. The complete and rigorous ſyſtem of the octave is compoſed of three major tones and two minor. The tempered ſyſtem is compoſed of five equal tones, and two ſemitones, forming altogether as many diatonic degrees upon the ſeven ſounds of the gammut, till arrived at the octave of the generator or firſt ſound. But as each tone may be divided into two nominal ſemitones, the ſame octave divides itſelf alſo chromatically into twelve intervals of a ſemitone each, of which the ſeven preceding keep their names, and the five others take the name of the next diatonic ſound below by a ſharp and above by a flat. See SCALE.

We do not ſpeak here of diminiſhed or ſuperfluous octaves, becauſe this interval admits of no alteration either in the melody or harmony.

It is forbidden in compoſition to admit of two ſucceſſive octaves between two different parts, eſpecially by ſimilar motion; but that is admitted, and with an elegant effect, when done with deſign and propriety through a whole air or period: thus, in many concertos all the ripieno parts play in octaves or uniſons.

OCTAVE, concerning the règle de l'octave, ſee RÈGLE or RULE.

OCTAVE, *Diminiſhed*. See DIMINISHED *Octave*, and INTERVAL.

OCTAVE, or *Octabis*, in *Law*, denotes the eighth day after any feaſt, incluſively; which ſpace is alſo called *utas*.

OCTAVE, among the Romaniſts, is uſed for the ſpace or period of eight days allowed for the celebration of a feaſt, or ſervice, in commemoration of ſome ſaint, or on other ſolemn occaſions.

Eaſter, Whitſuntide, St. John Baptiſt, St. Laurence, Epiphany, the Dedication, &c. are celebrated with octaves. The office in the octave is ſemi-double.

OCTAVIA, in *Biography*, a Roman lady diſtinguiſhed for her virtues and accompliſhments, was the daughter of Caius Octavius, the father of the emperor Auguſtus. Suetonius indeed ſays, ſhe had the ſame mother with that emperor, but according to Plutarch, ſhe was the daughter of a former wife of Octavius. She was accordingly either ſiſter or half-ſiſter to the emperor. She was firſt married to Claudius Marcellus, by whom ſhe had two children before his death, which happened a little after the war of Perſia, when ſhe was pregnant of a third child. After this ſhe married the triumvir Mark Antony, as the medium of reconciliation between him and her brother. At this time ſhe was extremely beautiful, univerſally reſpected and eſteemed, and tenderly beloved by her brother. Antony had previouſly to this been captivated by the allurements of Cleopatra, but the merits of Octavia appeared to make a proper impreſſion upon him, and he paſſed ſome time in conjugal union with her, during which ſhe bore him two daughters. She accompanied him into Greece, and had a ſecond opportunity of reſtoring concord between her huſband and brother. She returned to Rome, while Antony went into the Eaſt; then it was, ſays Plutarch, "that the worſt of all diſeaſes, love, and the love of Cleopatra, which had lain ſo long dormant in his breaſt, and ſeemed to have given place to the temperate duties of life, upon his approach to Syria, gathered ſtrength, and broke out into a flame:" he had another interview with her, which rivetted his fetters, and ſealed his fate. Octavia was ſoon apprized of his infidelity, but determining he ſhould have no pretence for his miſconduct, reſolved to omit no duty that became her ſituation as his wife: ſhe collected conſiderable ſupplies for the war, in which he was engaged, and ſailed with them

them to Athens. Here ſhe received the mortifying and diſtreſſing orders to advance no farther. Deſpairing now of a renewal of his affection, ſhe returned to Rome. Auguſtus, extremely enraged at this treatment of a beloved ſiſter, wiſhed to perſuade her to retire from the world. But ſhe refuſed to quit her huſband's houſe, and preſerving the dignity of her ſtation, devoted herſelf to the education of her children, beſtowing no leſs care on thoſe of Antony by Fulvia, than ſhe did upon her own. She readily and liberally entertained all her huſband's friends who were ſent to Rome on buſineſs, and uſed her beſt endeavours to promote his intereſt. His attachment, however, to Cleopatra rendered him inſenſible to her kindneſs; he ſolemnly divorced her and married Cleopatra. The Roman people were not leſs indignant than her brother at this profligate conduct, which Octavia herſelf, we are informed, chiefly lamented on this account, that ſhe ſhould become one of the cauſes of a civil war. After the death of her unfeeling huſband, ſhe even undertook the care of his children by Cleopatra, and married the daughter to Juba, king of Mauritania. Her own ſon Marcellus lived to be the hope of the empire, and was conſidered as the heir of Auguſtus, but his untimely death threw the mother into a ſtate of dejection, bordering upon abſolute deſpair, from which ſhe never recovered. The effect upon her of Virgil's beautiful lines, in the ſixth Æneid, in commemoration of that lamented youth, is highly characteriſtic of a mother's feelings. When the poet, reciting them in her preſence, came to the name, of Marcellus, artfully ſuppreſſed, to make the cloſe and climax of the paſſage, Octavia fainted away. On her recovery, ſhe expreſſed her gratitude for ſo noble an effort of genius conſecrated to her ſorrow, by a moſt munificent recompence. Octavia ſurvived the loſs of her beloved ſon about twelve years, the whole of which ſhe ſpent in mourning, refuſing that conſolation which her other children were capable of affording, and remaining in darkneſs and ſolitude. She died in the year 11 before the birth of Chriſt, and very extraordinary honours were paid to her memory by her brother and the ſenate. See the article Antony. Suetonius. Plutarch.

OCTAVIER, Fr. in *Muſic*. When a wind inſtrument is over blown, the tone inſtantly breaks into the octave. This is what the French verb octavier implies. In thus forcing the inſpiration, the air incloſed in the tube, and conſtrained by the outward air, is obliged to give way to the velocity of the oſcillations, and to divide itſelf into two equal columns, having each half the length of the tube; and thus each of the halves ſounds the octave of the whole. A ſtring of a violoncello, upon the ſame principle, breaks into the octave, when the ſtroke of the bow is too violent, or too near the bridge. It is one of the defects of an organ, when a pipe has too much or too ſtrong a wind to give the octave inſtead of the real ſound.

OCTAVINA, in the *Italian Muſic*, a kind of ſmall ſpinet, eaſily moved, having only one row of keys, and thoſe not to the uſual number, perhaps not more than three, the common ones extending to five. See Spinet.

OCTELINE, another appellation for the ſame diminutive kind of inſtrument.

OCTEVILLE, in *Geography*, a town of France, in the department of the Channel, and chief place of a canton, in the diſtrict of Valognes. The place contains 850, and the canton 13,303 inhabitants, on a territory of 19 kiliometres, in 17 communes.

OCTILE, in *Aſtrology*. See Octant.

OCTO, *Ad* Octo. See Ad Octo.

Octo *Tales*. See Tales.

OCTOBER, the eighth month of the year in Romulus's calendar; though the tenth in that of Numa, Julius Cæſar, &c. conſiſting of thirty-one days.

October has ſtill retained its firſt name in ſpite of all the different names the ſenate and Roman emperors would have given it. The ſenate ordered it to be called Fauſtinus, in honour of Fauſtina, the wife of Antoninus the emperor: Commodus would have had it bear the name of Invictus: and Domitian made it be called Domitianus, after his own name.

OCTOBLEPHARUM, in *Botany*, ſo named from οκτω, *eight*, and βλεφαρον, *the eye-laſh*, a genus of Moſſes founded by Hedwig, upon the *Bryum albidum* of Linnæus, its only known ſpecies. The plan of Hedwig's ſyſtem required the eſtabliſhment of this genus, and it happens that nature here confirms his artificial principle. (See Fringe *of Moſſes*, and Hedwig.) Hedw. Sp. Muſc. 50. Crypt. v. 3. 15. Bridel. Muſc. v. 2. 50. (Octoblepharis; Schreb. 758.) Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Eſſ. Ch. Fringe of eight ſimple equidiſtant teeth. Capſule without an apophyſis.

1. O. *albidum*. Hedw. Crypt. faſc. 3. t. 6. f. A. (Bryum albidum; Linn. Sp. Pl 1583. Swartz Obſ. t. 11. B. nanum, larignis foliis albis; Dill. Muſc. 364. t. 46. f. 21.) —Dillenius received this moſs from "Providence iſland in America," but from which of the two iſlands ſo named does not appear. Dr. Swartz found it in Jamaica, and we have the ſame from the Eaſt Indies, gathered by Dr. F. Buchanan. The frequent coincidence between the cryptogamic vegetables of the two Indies, is a curious circumſtance in the philoſophy of botany; as well as that between the aquatic plants of widely diſtant, and even different, climates. This is a ſmall perennial moſs, forming tufts on the trunks of trees, and remarkable for its white, rather opaque, though glittering, colour, with ſcarcely a tinge of green, in which reſpects it agrees with our *Dicranum glaucum*, and the *Sphagnum*, or Bog-Moſs, abſorbing moiſture, like them, with the greateſt rapidity, though ever ſo long dried. The *leaves* are linear, ſomewhat ſpatulate, entire, ſpongy, without any rib, ſpreading in every direction, ſcarcely half an inch long. *Anthers* red, in axillary tufts, ſurrounded by four leaves. *Capſules* on the ſame plant, axillary, elliptical, ſmooth, pale brown, their ſtalks about half an inch long, erect. *Lid* conical, acute, ſhorter than the capſule. *Fringe* reddiſh-brown, its teeth broad at the baſe, ſhort, acute.

OCTOGON, or Octagon, in *Geometry*, a figure of eight ſides, and eight angles.

When all the ſides and angles are equal, it is called a *regular* octogon, or an octogon that may be inſcribed in a circle.

To make an octogon on a given line A B. Erect A F and B E (*Plate* X. *Geometry*, *fig.* 8.) perpendicular to A B: produce A B both ways, and biſect the angles *m* A F and *n* D E with the lines A H and B C, each equal to A B: draw C D and H G parallel to A F or B E, and each equal to A B: with the radius A B, and on the centres G and D, deſcribe arcs interſecting A F and D E in F and E: then join G F, F E, E D, and A H G F E D C B is the figure required. In or about a given circle, to deſcribe a ſquare, or an octogon; draw two diameters, A B, C D, perpendicular to each other; then connect their extremities, and we ſhall have the inſcribed ſquare A C B D: alſo through their extremities draw tangents parallel to them, and they will form the outer ſquare *m n o p*. If any quadrant, as A C, be biſected in *q*, it will give one-eighth of the circum-

circumference, or the ſide of the octogon. To find the area of an octogon, ſee POLYGON.

OCTOGON, in *Fortification*, denotes a place that has eight baſtions. See BASTION.

OCTOPHORUM, among the *Ancients*, a carriage with eight wheels.

It alſo ſignified a chair, or litter, *lectica*, carried by eight chairmen, which kind of chair was moſtly uſed by the women.

OCTOPITARUM, in *Ancient Geography*, a promontory of Albion, which is evidently St. David's Head in Pembrokeſhire.

OCTOSPORA, in *Botany*, from οκτω, *eight*, and σπορος, *a ſeed*, a genus of *fungi* eſtabliſhed by Hedwig, of which he gives the following character, in his Crypt. v. 2. 4.

"Trunk perfectly ſimple, terminated by a fertile ſurface, which is either concave, flat, or reflexed; and out of which proceed very numerous, elongated, delicately membranous ſeed-caſes, generally ſurrounded with a filamentous ſubſtance, not connected among themſelves, each of them producing eight ſeeds."

Schreber adopts this genus, in his Gen. 770, but the profeſſed writers on *Fungi*, though uſually ſo prolific in genera, entirely neglect this, retaining the plants which compoſe it in the eſtabliſhed genus of *Peziza*, to which they properly belong. Indeed the character of the ſeeds and their caſes is exactly the ſame as in the old genus *Lichen*, or rather in nearly the whole of the natural order of LICHENES; ſee that article. We do not mean that this would be any objection to its diſtinguiſhing a genus of *Fungi*, having no other character in common with the *Lichenes*, were it wanted for that purpoſe. See PEZIZA.

OCTOSTYLE, in the *Ancient Architecture*, the face of a building, or ordonnance, containing eight columns.

The eight columns of the octoſtyle may either be diſpoſed in a right line, as in the Pſeudodiptere temple of Vitruvius, and in the Pantheon; or in a circle, as in the round Monoptere temple of Apollo Pythius at Delphi, &c.

OCTUNX, a word uſed by ſome diſpenſatory writers to ſignify eight ounces.

OCULATA, in *Ichthyology*, a name given by many to the fiſh more uſually called *melanurus*. It has the name *oculata*, from the remarkable largeneſs and fine golden iris of its eye. See SPARUS *Melanurus*.

OCULATUS LAPIS, the *Eyed-ſtone*, in *Natural Hiſtory*, a name given by Mercatus, in his "Metallotheca Vaticana," and, by many other writers, to what we call the *pudding-ſtone*, a ſtone formed of a great number of pebbles, of a ſmall ſize, immerſed, and formerly bedded in a flinty cement, little leſs hard than the ſtones themſelves, and in ſome ſpecies not at all ſo. The reſemblance of theſe round pebbles, when the maſs was cut, to the eyes of animals, probably gave origin to this name.

OCULI, EYES, in *Botany*, the gemmæ or buds of a plant juſt putting forth, or the knots out of which thoſe buds ariſe.

OCULI, *Abductor*, *Depreſſor*, *Elevator*, and *Obliquus*, in *Anatomy*. See the reſpective articles.

OCULI *Speculum*. See SPECULUM.

OCULIST is a name appropriated to a ſurgeon, who applies himſelf particularly to the ſtudy and cure of diſeaſes of the eye.

OCULO-MUSCULARES, in *Anatomy*, the nerves of the third pair, which ſupply the muſcles of the eyes. (See NERVE.) It is alſo called motor oculi.

OCULUS. See EYE.

OCULUS *Beli*, in *Natural Hiſtory*, the name of one of the ſemi-pellucid gems of the genus of the Hydrophanæ, or the greyiſh-white hydrophanes variegated with yellow, and with a black central nucleus.

It is a very elegant and beautiful gem; its baſis, or ground, is a whitiſh-grey, variegated with yellow, and ſometimes with red, and a little black, but that more rarely, and is found in ſmall maſſes from half an inch to an inch in diameter; of a rounded figure, and thickeſt in the middle, tapering away gradually to the ſides; the outer part of the ſtone, or that towards the edges all round, is ever of a whitiſh-grey, more or leſs variegated with yellow, &c. and its central nucleus is always of a deep and fine black, ſurrounded by a broad circle, of a pale yellow, and repreſenting very beautifully the pupil and iris of the eye; theſe are encloſed in the matter of the ſtone, and are often ſurrounded by other very fine concentric circles, of a pale flame-colour; but more frequently there is only the black pupil, ſurrounded by the yellow iris, and that placed in the body of the ſtone which repreſents the white of the eye; the ſhape of the ſtone alſo favours its reſemblance of an eye, and the whole is very elegant. It is of the hardneſs of the agate, and takes a tolerable poliſh; when thrown into water, it has, in a great meaſure, the property of the oculus mundi, the whole ſtone becomes greatly more bright and lucid, and the grey part becomes of a plainly yellowiſh caſt.

There are many things improperly called oculus beli by our jewellers, but the genuine ſpecies is very rare. Nothing is more common than to find in the agates little circular veins of different colours round a central ſpot; theſe the lapidaries frequently cut out, with a proper quantity of the ſtone about them, and call them oculus beli. They are not peculiar to the agate, but are common alſo in the cornelian, and ſtand ſometimes ſingle, ſometimes two or three together, and according to the colours of the circles, repreſent the eyes of various animals. See GEM.

OCULI *Cancrorum*. See CRAB'S *Eyes*.

OCULUS *Cati*. See ASTERIA and GEM.

OCULUS *Chriſti*, in *Botany*, a name given to a ſpecies of clary, from the ſuppoſed virtues of its ſeeds in clearing the ſight, which it does by its viſcous covering; for when any thing happens to fall into the eye, if one of theſe ſeeds is put into one corner, and the eye-lid kept cloſe over it, moving the ſeed gently along the eye, whatever happens to be there will ſtick to the ſeed, and ſo be brought out.

OCULUS *Leporinus*, a diſtemperature of the eyes, called alſo *ectropium*.

OCULUS *Marinus*, the *ſea-eye*, a name given by ſome authors to the umbilicus marinus, from its reſemblance to the ſhape of an eye.

OCULUS *Mundi*, in *Natural Hiſtory*, the name of one of the ſemi-pellucid gems of the genus of the Hydrophanæ. It is of one plain and uniform colour, which is a whitiſh-grey, and has no veins, or other variegations. It is found in ſmall maſſes, of the ſhape of our common flints and pebbles; it has but a very obſcure degree of tranſparence, and is not capable of a fine poliſh. This ſtone, however, though of little beauty, has this very ſingular property, that, when thrown into a baſon of water, in the ſpace of half a minute it begins to change its appearance, and very ſoon, inſtead of a pale grey, becomes of a very bright, and conſiderably pellucid, pale yellow, like that of amber, or the yellow cornelian; this it retains as long as it remains in the water, but as ſoon as taken out and dried, it reſumes its grey colour, and becomes as opaque as before. It is found, ſo far as is yet known, only in China; but the ſhores of ſome of our own rivers afford us ſtones coming up to its qualities

in

in ſome degree, though not ſo beautifully tranſparent in water as the oriental. See GEM (*opal*).

OCULUS *Veneris*, a name given by ſome to the umbilicus marinus.

OCUMARA, *Bay of*, in *Geography*, a bay of the province of Caraccas, in Terra Firma, South America, 5 leagues E. of Porto-Cabello, which is a very good and well-ſheltered port. It has excellent moorings; and the port is defended, on the E., by a battery mounting eight pieces of cannon. The village of Ocumara is at the diſtance of one league from the port, and is watered by a river of the ſame name, which, after fertiliſing its vallies, diſcharges itſelf into the ſame bay at the bottom of the fort. Between the bay of Ocumara and that of Guayra, are ſeveral ſmall ports, where the inhabitants of that coaſt ſhip their commodities for Guayra, or Porto-Cabello; but none of them very important. Dupons's Travels, vol. i.

OCUNHAZARY, a town of Bengal; 20 miles N.N.W. of Ramgur.

OCYMOPHYLLON, in *Botany*. See ISNARDIA.

OCYMUM. See OCIMUM.

OCZE, in *Geography*, a town of European Turkey, in Moldavia; 44 miles W.N.W. of Birlat.

OCZYCE, a town of Lithuania; 40 miles S.E. of Minſk.

ODA, in the *Turkiſh Seraglio*, ſignifies a claſs, chamber, or order.

The grand ſignior's pages are divided into five claſſes, or chambers, called *odas*. See PAGE.

The firſt, which is the loweſt in dignity, is called the *great oda*, from the number of perſons that compoſe it.

Theſe are the juniors, who are taught to read, write, and ſpeak the languages; which are, the Turkiſh for this world; the Arabic for paradiſe; and the Perſian for hell, by reaſon of the hereſy of the people that ſpeak it.

The ſecond is called the *little oda*; where, from the age of fourteen or fifteen years, the youth are trained up to arms, and the ſtudy of ſuch polite learning as the Turks are acquainted with; *viz.* logic, arithmetic, geometry, and a little aſtrology.

In each of theſe chambers is a page of the privy-chamber, who ſuperintends them, as the prefects in the colleges of the Jeſuits.

The third chamber, called *kilar-oda*, comprehends two hundred pages; which, beſides their other exerciſes, are commanded by the kilerdgi-bachi, for the ſervice of the buttery and fruitery.

The fourth only conſiſts of twenty-four; theſe, under the khazineda-bachi, take care of the treaſure in the grand ſignior's apartment, where they never enter with any clothes on that have pockets.

The fifth is called *khas-oda*, *i. e.* privy chamber, and conſiſts of forty pages, which attend the emperor's bed-chamber. The firſt of this chamber is called *oda bachi*, the ſecond *ſiliktar*, &c.

Eight of theſe pages keep conſtant guard every night in the emperor's bed-chamber: they are poſted in ſeveral places, ſome nearer him, others farther off, according to their degrees in the chamber. They are to take care the lights, kept conſtantly in the chamber, do not glare in his eyes, and awake him; and if they find him diſturbed with any troubleſome dream, to take care he be awaked by one of the agas.

ODABACHI, or ODDABASSI, an officer in the Turkiſh ſoldiery, equivalent to a ſerjeant or corporal among us.

The common ſoldiers, and janizaries, called *oldachis*, after having ſerved a certain term of years, are always preferred, and made biquelairs; and of biquelairs, in time, become odabachis, *i. e.* corporals of companies, or chiefs of certain diviſions, whoſe number is not fixed; being ſometimes ten, and ſometimes twenty.

Their pay is ſix doubles *per* month, and they are diſtinguiſhed by a large felt, a foot broad, and above a foot long, hanging on the back, with two long oſtrich feathers.

ODALIKS, ſo called from the word *oda*, ſignifying chamber, a denomination given to ſlaves attached to the ſeraglio of the grand ſignior, in contradiſtinction to thoſe ſeven, who are ſelected as his favourites, who participate moſt commonly in his pleaſures, and who ſometimes acquire no ſmall degree of influence over public affairs. Theſe are diſtinguiſhed by the appellation of "Kadeun." If one of the odaliks be pregnant, ſhe is treated with great attention: the eunuchs ſerve her with the greateſt reſpect when the ſultan has no male children: on the contrary, ſhe finds herſelf in a very critical ſituation when he has any by a ſlave in favour. She is then fortunate if ſhe eſcape by miſcarrying, as the child is ſmothered at its birth. For one of theſe odaliks to become kadeun, an honour very ardently wiſhed by all, it is neceſſary that the grand ſignior ſhould ſend one of the ſeven favourites to the old ſeraglio, the place of exile for his women who have miſbehaved or have had the misfortune to diſpleaſe.

ODAVARA, in *Geography*, a town of Japan, in the iſland of Niphon, ſituated in the gulf of Jedo; 40 miles S.S.W. of Jedo.

ODD. See EVENLY, and FOOT.

ODDENA, in *Geography*, a town of Arabia, formerly a ſplendid city, now in ruins, near Taas.

ODDER, a town of Arabia, in the province of Yemen; 12 miles S. of Wadeij.

ODE, a Greek word implying a melody or ſong. Rouſſeau.

ODE, *Oda*, from the Greek ᾠδή, *cantus*, *ſong*, or *ſinging*, in the *Ancient Poetry*, a ſong or hymn; or a compoſition proper to be ſung, and compoſed for that purpoſe; the ſinging being uſually accompanied with ſome muſical inſtrument, chiefly the lyre. See LYRIC *Poetry*.

The peculiar and diſtinguiſhing character of the ode is, that it is intended to be ſung, or accompanied with muſic; and though this diſtinction was not peculiar to any one ſpecies of poetry, becauſe muſic and poetry were coeval and originally always joined together, yet after their ſeparation, and when bards produced compoſitions in verſe that were to be recited or read, not to be ſung, ſuch poems as were deſigned to be ſtill joined with muſic or ſong, are, by way of diſtinction, called odes. It is from this circumſtance of the ode's being ſuppoſed to retain its original union with muſic, that we are to deduce the peculiar and diſcriminating qualities of this kind of poetry. Muſic and ſong naturally add to the warmth of poetry; and they juſtify a bolder and more paſſionate ſtrain than can be ſupported in ſimple recitation. From this is formed the peculiar character of the ode. Hence, ſays Dr. Blair, proceed "the enthuſiaſm that belongs to it, and the liberties it is allowed to take beyond any other ſpecies of poetry. Hence, that neglect of regularity, thoſe digreſſions, and that diſorder, which it is ſuppoſed to admit; and which, indeed, moſt lyric poets have not failed ſufficiently to exemplify in their practice. The effects of muſic upon the mind are chiefly two; to raiſe it above its ordinary ſtate, and fill it with high enthuſiaſtic emotions; or to ſoothe, and melt it into the pleaſurable feelings. Hence, the ode may either aſpire to the former character of the ſublime and noble, or it may deſcend to the latter of the pleaſant and the gay; and between theſe there is, alſo, a middle region, of the

the mild and temperate emotions, which the ode may often occupy to advantage." The ode, ſays the learned biſhop Lowth,

"With thoughts that breathe, and words that burn,"

although inferior in ſome reſpects to the epic or what are called the higher ſpecies of poetry, yields to none in force, ardour, and ſometimes even in dignity and ſimplicity. Whilſt "the epic accompliſhes its deſign with more leiſure, with more conſideration and care, and therefore probably with greater certainty,"—"the ode, on the contrary, ſtrikes with an inſtantaneous effect, amazes, and, as it were, ſtorms the affections. The one may be compared to a flame, which, fanned by the winds, gradually ſpreads itſelf on all ſides, and at laſt involves every object in the conflagration; the other to a flaſh of lightning, which inſtantaneouſly burſts forth,

"With inſtant ruin threats great Nature's frame,
And ſhoots through every part the vivid flame."

"The amazing power of lyric poetry in directing the paſſions, in forming the manners, in maintaining civil life, and particularly in exciting and cheriſhing that generous elevation of ſentiment, on which the very exiſtence of public virtue ſeems to depend, will be ſufficiently apparent by only contemplating thoſe monuments of genius, which Greece has bequeathed to poſterity." Among them we may reckon firſt and principally, and almoſt ſolely, the poems of Pindar. The nature of the ode ſufficiently expreſſes its origin: it was the offspring of the moſt vivid and the moſt agreeable paſſions of the mind, of love, joy and admiration; and accordingly it muſt have been coeval with the firſt creation of man. Sentiments correſponding to ſuch a compoſition evidently dictated the hymn which occurs in the cxlviiith pſalm; and which is moſt elegantly imitated and put into the mouth of Adam by Milton (Parad. Loſt, b. v.), who is juſtly accounted, ſays the learned prelate now cited, the next in ſublimity to thoſe poets who wrote under the influence of divine inſpiration. If we appeal to the common teſtimony of hiſtory we ſhall find that, among every people not utterly barbarous, the uſe of muſic and poetry, in the celebration of their religious myſteries, has prevailed from the firſt periods of ſociety. Plato aſſigns the firſt rank to that ſacred melody which aſſumed the form of addreſſes to the Deity, and was diſtinguiſhed by the appellation of hymns. Accordingly the Salian poems of Numa, compoſed on the firſt inſtitution of the religious rites of that wiſe and learned monarch, are the moſt ancient of any that occur in the Latin poetry; and the moſt ancient poem extant, whoſe date is aſcertained, is the thankſgiving ode of Moſes on paſſing the Red ſea; the moſt perfect in its kind, and the true and genuine effuſion of the joyful affections. Thus the origin of the ode may be traced into that of poetry itſelf, and appears to be coeval with the commencement of religion, or more properly the creation of man. The Hebrews cultivated this kind of poetry more than any other, and are allowed to have excelled in it. Hence we have the triumphal odes of Moſes, of Deborah, and of David. Sacred poetry was a principal object of ſtudy in the ſchools of the prophets, which were antecedent to the monarchy for many years, if not coeval with the republic; and young perſons thus educated celebrated the praiſes of Almighty God in lyric compoſitions, accompanied with muſic. It was, however, under the government of David, that the arts of muſic and poetry were in their moſt flouriſhing ſtate. (See Hebrew *Muſic* and Hebrew *Poetry*.) "Of all the different forms of poetical compoſition," ſays the prelate, of whoſe admirable work we here avail ourſelves, "there is none more agreeable, harmonious, elegant, diverſified and ſublime, than the ode; and theſe qualities are diſplayed in the order, ſentiments, imagery, diction and verſification. The principal beauty of an ode conſiſts in the order and arrangement of the ſubject;" nevertheleſs, "the form of the ode is by no means confined to any certain rule for the exact and accurate diſtribution of the parts. It is lively and unconſtrained: when the ſubject is ſublime, it is impetuous, bold, and ſometimes might almoſt deſerve the epithet licentious as to ſymmetry and method; but even in this caſe, and uniformly in every other, a certain facility and eaſe muſt pervade the whole, which may afford at leaſt the appearance of unaffected elegance, and ſeem to prefer nature to art. This appearance is beſt preſerved by an exordium plain, ſimple, and expreſſive; by a diſplay and detail of incidents and ſentiments riſing delicately and artfully from each other, yet without any appearance of art; and by a concluſion not pointed or epigrammatic, but finiſhing by a gentle turn of the ſentiment where it is leaſt expected, and ſometimes as it were by chance," in which latter reſpect the beſt Arabic odes are entitled to peculiar commendation.

"It is not the metre or verſification which conſtitutes this ſpecies of compoſition; for unleſs all theſe circumſtances be adverted to, it is plain that whatever be the merit of the production, it cannot with any propriety be termed an ode. Many of the odes of Horace are entirely in this form, as well as almoſt all of thoſe few which our countryman Hanmer has left behind him." "The ſentiments and imagery muſt be ſuitable to the nature of the ſubject and the compoſition, which is varied and unconfined by ſtrict rule or method. On familiar ſubjects, they will be ſprightly, florid, and agreeable; on ſublime topics, ſolemn, bold, and vivid; on every ſubject highly elegant, expreſſive, and diverſified. Imagery from natural objects is peculiarly adapted to the ode; hiſtorical common-places may alſo be admitted, as well as deſcriptions lively but ſhort, and (when it riſes to any uncommon ſtrain of ſublimity) frequent perſonifications. The diction muſt be choice and elegant; it muſt be alſo luminous, clear, and animated; it muſt poſſeſs ſome elegancies peculiar to itſelf, and be as diſtinct from the common language of poetry, as the form and faſhion of the production is from the general caſt of poetical compoſition. In this that happineſs of expreſſion, for which Horace is ſo juſtly celebrated, wholly conſiſts. A ſweetneſs and variety in the verſification are indiſpenſible, according to the nature of the language, or as the infinite diverſity of ſubjects may require." In the Hebrew ode the numbers or verſification were probably accommodated to the muſic, and agreeable to the genius of the language; but this is a circumſtance concerning which we cannot form any deciſive judgment. In every other reſpect, ſuch as the force and elegance of the language, the beauty and dignity of the ſentiments and imagery, the different graces and excellencies of order and arrangement, biſhop Lowth does not heſitate in preferring the Hebrew writers to the lyric poets of every other nation. Our learned author diſtributes all the diverſities of this ſpecies of compoſition into three general claſſes. "Of the firſt claſs, the general characteriſtic will be ſweetneſs; of the laſt, ſublimity; and between theſe we may introduce one of a middle nature, as partaking of the properties of both. The qualities which may be accounted common to all the three claſſes, are variety and elegance." To the firſt of theſe claſſes Michaelis refers the Pſalms of David. See Psalms.

"The ſweetneſs of the Hebrew ode conſiſts in the gentle and tender paſſions which it excites; in the gay and florid imagery, and in the chaſte and unoſtentatious diction which

it employs. The paſſions which it generally affects are thoſe of love, tenderneſs, hope, cheerfulneſs, and penſive ſorrow. In the 63d pſalm, the royal prophet, ſuppoſed to be then an exile in the wilderneſs, expreſſes moſt elegantly the ſentiments of tenderneſs and love. The voice of grief and complaint is tempered with the conſolations of hope in the 80th pſalm; and the 92d conſiſts wholly of joy, which is not the leſs ſincere, becauſe it is not exceſſive. The ſweetneſs of all theſe, in compoſition, ſentiment, diction, and arrangement, has never been equalled by the fineſt productions of all the Heathen muſes and graces united." Other pſalms particularly entitled to notice and commendation for their peculiar and diſcriminating excellencies, are the 23d, the 65th, the 72d, and the 133d. This latter is produced by our author as a ſpecimen, expreſſive of the true lyric form and character, and compreſſing in a ſmall compaſs all the merits and elegance incidental to that ſpecies of compoſition. "It is," he ſays, "if I may be allowed the expreſſion of a very polite writer,

> "A drop of Helicon, a flower
> Cull'd from the Muſe's favourite bower."
> Callimach. Hymn. in Apoll. v. 112.

This pſalm is one of the fifteen which are entitled "Odes of the Aſcenſions;" that is, which were ſung when the people *came* up either to worſhip in Jeruſalem at the annual feſtivals, or perhaps from the Babyloniſh captivity. The *return* is certainly called "the *aſcenſion* or *coming up* from Babylon." Ezr. vii. 9.

One of the grand diviſions of the order of poems now under conſideration, which is conſtituted by that middle ſtyle of compoſition, to which we have above referred, may include both thoſe lyric compoſitions, in which ſweetneſs and ſublimity are ſo uniformly blended, that every part of the poem may be ſaid to partake equally of both; and thoſe, in which theſe qualities ſeparately occur in ſuch a manner that the complexion of the poem is altogether changed and diverſified. As examples of each ſpecies we may refer to the 91ſt pſalm, which is ſuppoſed to excel the third ode of the fourth book of Horace (though juſtly celebrated), as well in grace and elegance, as in force and dignity; and the 81ſt pſalm, which affords a correct idea of this kind of poem, ſo that any one who makes himſelf maſter of its general character, genius and arrangement, will feel perfectly ſatisfied concerning the nature and form of a perfect ode. "In both theſe ſpecimens, the ſtyle and cadence of the whole poem flow in one equal and uniform tenour: but there are others, which are more changeable and diverſified, more unequal both in ſtyle and ſentiment. Theſe, though they occaſionally incline to the character of ſweetneſs, and occaſionally to that of ſublimity, may nevertheleſs, (though upon a different principle,) be properly claſſed among the odes of this intermediate ſtyle. Such are thoſe which, from a mild and gentle exordium, riſe gradually to ſublimity, both in the ſubject and ſentiments; ſuch alſo are thoſe which commence in a mournful ſtrain, and conclude with exultation and triumph. Such, in fine, are all thoſe in which the ſtyle or matter is in any reſpect diverſified and unequal. This inequality of ſtyle is perfectly conſiſtent with the nature of lyric compoſition, for variety is one of the greateſt ornaments, if not eſſentials, of the ode." (See HEBREW *Poetry*.) "The 77th pſalm will afford ſome illuſtration of what has been remarked concerning the nature and economy of the Hebrew ode. This pſalm is compoſed in what I call the intermediate ſtyle, and is of that diverſified and unequal kind, which aſcends from a cool and temperate exordium, to a high degree of ſublimity." On the other hand, the 19th pſalm is compoſed upon a different plan; "for it declines gradually from an exordium uncommonly ſplendid and ſublime, to a gentler and more moderate ſtrain, to the ſofteſt expreſſions of piety and devotion. The whole compoſition abounds with great variety, both of ſentiment and imagery."

Of the ſublimity which is characteriſtic of a third ſpecies of the Hebrew ode, and which reſults either from the plan, the order and arrangement of the poem, or from the ſentiments and the ſtyle, or from an union of all, when an aggregate perfection is produced from the beauty of the arrangement, the dignity of the ſentiments, and the ſplendour of the diction, we have examples in the 50th pſalm, the 24th pſalm, and the thankſgiving ode of Moſes, compoſed after paſſing the Red ſea (Exod. xv.) already mentioned, and the 29th pſalm. As ſpecimens of that kind of ode which derives ſublimity from ſeveral united cauſes, from the diction, the ſentiments, the form and conduct of the poem, and which accumulates, or in a manner condenſes and combines all the beauties and elegancies of this ſtyle of compoſition, we may mention the prophetic ode of Moſes (Deut. xxxii.), the triumphal ode of Deborah, the prayer of Habakkuk (ch. iii.), and the triumphal ſong of the Iſraelites on the deſtruction of Babylon (Iſaiah, xiv.)

"All odes," ſays Dr. Blair, "may be compriſed under four denominations. 1. Sacred odes; hymns addreſſed to God, or compoſed on religious ſubjects. Of this nature are the Pſalms of David, which exhibit to us this ſpecies of lyric poetry in its higheſt degree of perfection. 2. Heroic odes, which are employed in the praiſe of heroes, and in the celebration of martial exploits and great actions. Of this kind are all Pindar's odes, and ſome few of Horace's. Theſe two kinds ought to have ſublimity and elevation for their reigning character. 3. Moral and philoſophical odes, where the ſentiments are chiefly inſpired by virtue, friendſhip, and humanity. Of this kind are ſeveral of Horace's odes, and ſeveral of our beſt modern lyric productions; and here the ode poſſeſſes that middle region which it ſometimes occupies. 4. Feſtive and amorous odes, calculated merely for pleaſure and amuſement. Of this nature are all Anacreon's; ſome of Horace's; and a great number of ſongs and modern productions, that claim to be of the lyric ſpecies. The reigning character of theſe ought to be elegance, ſmoothneſs, and gaiety." Lowth's Lectures on the Sacred Poetry of the Hebrews by Gregory, vol. ii. Blair's Lectures, vol. iii.

ODE, in the *Modern Poetry*, is a lyric poem, conſiſting of long and ſhort verſes, diſtinguiſhed into ſtanzas, or ſtrophes, wherein the ſame meaſure is preſerved throughout.

The ancient ode had originally but one ſtanza, or ſtrophe; but was at laſt divided into three parts; *ſtrophe*, *antiſtrophe*, and *epode*. The prieſts going round the altar, ſinging the praiſe of the gods, called their firſt entrance *ſtrophe*, *i. e.* turning to the left; the ſecond, turning to the right, they call *antiſtrophe*, *q. d.* returning: laſtly, ſtanding ſtill before the altar, they ſung the remainder; which they called *epode*.

The odes of the ancients, Voſſius obſerves, had a regular return of the ſame kind of verſe, and the ſame quantity of ſyllables, in the ſame place of every ſimilar verſe: "But there is nothing (ſays he) but confuſion of quantities in the modern odes; ſo that, to follow the natural quantity of our ſyllables, every ſtanza will be a different ſong.

He ſhould have obſerved, however, that all the ancient odes were not of ſuch kind. But he proceeds: "The moderns have no regard to the natural quantity of the ſyllables, and have introduced an unnatural and barbarous variety

riety of long and ſhort notes, which they apply without any regard to the natural quantity of ſyllables: ſo that it is no wonder our vocal muſic has no effect." De Poem. Cantu.

Among the ancients, ode ſignified no more than a ſong; with us, they are different things. The ancient odes were generally in honour of their gods, as are many of thoſe of Pindar and Horace; ſometimes on other ſubjects, as thoſe of Anacreon, Sappho, &c. The Engliſh odes are generally compoſed in praiſe of heroes, and great exploits; as thoſe of Dryden, Prior, &c.

The diſtinguiſhing character of the ode, as we have obſerved in the preceding article, is *ſweetneſs*; the poet is to ſooth the minds of his readers by the variety of verſe, and the delicacy of words; the beauty of numbers, and the deſcription of things moſt delightful in themſelves. Variety of numbers is eſſential to the ode. At firſt, indeed, the verſe of the ode was but of one kind; but for the ſake of pleaſure, and the muſic to which they were ſung, they by degrees ſo varied the numbers and feet, that their kinds are now almoſt innumerable.

Modern lyric writers aſſume to themſelves an extravagant liberty in their verſification; they prolong their periods to ſuch a degree, they wander through ſo many different meaſures, and employ ſuch a variety of long and ſhort lines, correſponding in rhyme at ſo great a diſtance from each other, that all ſenſe of melody is utterly loſt. Whereas lyric compoſition ought, more than any other ſpecies of poetry, to pay attention to melody and beauty of ſound; and the verſification of thoſe odes may be juſtly accounted the beſt, which renders the harmony of the meaſure moſt ſenſible to every common ear.

Pindar, the great father of lyric poetry, by the boldneſs and rapidity of his flights, has been the occaſion of leading his imitators into ſome of the defects, with which they are chargeable. His genius was ſublime; his expreſſions are beautiful and happy; his deſcriptions pictureſque. Finding it, however, a very barren ſubject to ſing the praiſes of thoſe who had gained the prize in the public games, he is perpetually digreſſive, and fills up his poems with fables of the gods and heroes, that have little connection either with his ſubject, or with one another. Although he was greatly admired by the ancients, he is now ſo obſcure, partly from his ſubjects in a great degree unknown to us, and partly from his rapid and abrupt manner of treating them, that, notwithſtanding the beauty of his expreſſions, our pleaſure in reading his poems is much diminiſhed. Many of his imitators ſeem to have thought that the reſemblance of his diſorder and obſcurity was the beſt method of imbibing and indicating his ſpirit. Euripides and Sophocles, in ſeveral of their choruſes, have the ſame kind of lyric poetry with Pindar, carried on with more clearneſs and connection, and at the ſame time with much ſublimity.

"Of all the writers of odes," ſays Dr. Blair, "ancient or modern, there is none that, in point of correctneſs, harmony, and happy expreſſion, can vie with Horace. He has deſcended from the Pindaric raptures, to a more moderate degree of elevation; and joins connected thought and good ſenſe with the higheſt beauties of poetry. He does not often aſpire beyond that middle region, 'which belongs to the ode;' and thoſe odes, in which he attempts the ſublime, are not always his beſt. The peculiar character, in which he excels, is grace and elegance; and in this ſtyle of compoſition, no poet has ever attained to a greater perfection than Horace. No poet ſupports a moral ſentiment with more dignity, touches a gay one more happily, or poſſeſſes the art of trifling more agreeably, when he chuſes to trifle. His language is ſo fortunate, that with a ſingle word or epithet, he often conveys a whole deſcription to the fancy. Hence he ever has been, and ever will continue to be, a favourite with all perſons of taſte. Among the poets of later days, there have been many imitators of Horace." The moſt diſtinguiſhed is Caſimir, who wrote four books of odes; but in graceful eaſe of expreſſion, he is far inferior to the Roman: he more frequently affects the ſublime, and in the attempt, like other lyric writers, often becomes harſh and unnatural. On ſeveral occaſions, however, he manifeſts much original genius and poetical fire. Buchanan, in ſome of his lyric compoſitions, is very elegant and claſſical. "Among the French, the odes of Jean Baptiſte Rouſſeau have been much and juſtly celebrated. They poſſeſs great beauty both of ſentiment and expreſſion. They are animated, without being rhapſodical; and are not inferior to any poetical productions in the French language. In our own language we have ſeveral lyric compoſitions of conſiderable merit. Dryden's ode on St. Cecilia is well known. Mr. Gray is diſtinguiſhed in ſome of his odes, both for tenderneſs and ſublimity; and in Dodſley's Miſcellanies, ſeveral very beautiful lyric poems are to be found. As to profeſſed Pindaric odes, they are, with a few exceptions, ſo incoherent as to be ſeldom intelligible. Cowley, at all times harſh, is doubly ſo in his Pindaric compoſitions. In his Anacreontic odes he is much happier: they are ſmooth and elegant, and, indeed, the moſt agreeable, and the moſt perfect, in their kind, of all Mr. Cowley's poems." In thoſe odes, ſays Dr. Johnſon, where Cowley chooſes his own ſubjects, he ſometimes riſes to dignity truly Pindaric.

Ode, *Alcaic*. See Alcaic.

ODEH, in *Geography*, a town of Hindooſtan, in the ſubah of Agimere; 14 miles E. of Rantampour.

ODEIDA, a town of Arabia, in the province of Yemen; 80 miles N.E. of Aden.

ODEMIRA, a town of Portugal, in Alentejo; 24 miles S.W. of Ourique.

ODENATUS, in *Biography*, king of Palmyra, was originally a native and leading inhabitant of that commercial city; though ſome make him a prince of a tribe of Saracens, who dwelt in the neighbourhood of the Euphrates. After Sapor, king of Perſia, had rendered himſelf formidable throughout the Eaſt, by the defeat of the Roman emperor Valerian, A.D. 260, he received from Odenatus a preſent of ſeveral camels laden with rich merchandize, accompanied with a ſubmiſſive letter, proteſting that he had never borne arms againſt the Perſians. Sapor was enraged that he ſhould preſume to write to him, and threatened to deſtroy him, and exterminate his whole family, unleſs he came, and, with his hands tied behind him, ſolicited forgiveneſs. Odenatus ſpurned the conditions, and collecting an army, declared for the Romans. To him is aſcribed the ſucceſs of an expedition, in which Sapor's treaſure, and ſeveral of his wives and children, were captured; and ſo cloſely did he preſs upon the Perſian, that he forced him to retreat, and cut off his rear in paſſing the Euphrates. After theſe exploits, Odenatus aſſumed the title of king of Palmyra, and elevated his wife, the celebrated Zenobia, to the rank of queen. Gallienus, the ſon and colleague of Valerian, entruſted Odenatus with the chief command of the Roman army in the Eaſt. In this quality he entered Meſopotamia, defeated Sapor in his own country, and laid ſiege to Cteſiphon. Thus he had ample opportunity of making the haughty Perſian repent of the indignity with which he had treated him. In the following diſtracted ſtate of the Roman empire, when ſuch a number of rivals to Gallienus aroſe, that the period is called that of the thirty tyrants, Odenatus

preſerved his fidelity, and kept the Eaſt in a ſtate of tranquillity. On this account he was created Auguſtus, and partner in the empire, by Gallienus, in the year 264. Zenobia was dignified with the title of Auguſta, and their children with that of Cæſar. In a ſecond incurſion into the territories of Sapor, he ravaged the country, and took the city of Cteſiphon. On his return from this expedition, he marched againſt the Goths or Scythians, who had invaded Aſia, and obliged them to make to a haſty retreat. Shortly after this he fell a victim to domeſtic treaſon, and his favourite amuſement of hunting was the occaſion of his death. His nephew, Mæonius, preſumed to throw his javelin before that of his uncle; and though admoniſhed of his error, repeated the ſame. Odenatus was provoked at this ſhow of inſolence, took away his horſe, a mark of infamy among the barbarians, and ordered the youth into confinement for a ſhort time. The offence was ſoon forgotten, but the puniſhment was remembered, and Mæonius cauſed his uncle to be aſſaſſinated in the midſt of a great entertainment. Herod, the ſon of Odenatus by a former wife, was killed with his father. This tragedy is ſaid to have been acted at Emeſſa, in the year 267. Odenatus was a prince of great qualities, and one who well merited the high rank to which he had raiſed himſelf. Univer. Hiſt. Gibbon.

ODEN-HOTUN, in *Geography*, a town of Aſia, in the kingdom of Corea. N. lat. 40° 15′. E. long. 124° 53′.

ODENKIRCHEN, a town of France, in the department of the Roer, and chief place of a canton, in the diſtrict of Crèveldt. The place contains 1627, and the canton 16,295 inhabitants, in 22 communes.

ODENSALA, a town of Sweden, in the province of Upland; 14 miles S.E. of Upſal.

ODENSEE, a town of Denmark, and capital of the iſland of Funen, ſituated on a river which runs into a large bay of the Cattegat, about a mile from the town. It is the ſee of a biſhop, and contains three churches, beſides the cathedral, and a town-houſe. A conſiderable number of ſhips trade to and from this town. The king has a palace, and in 1621 Chriſtian IV. erected a college, and liberally endowed it for four profeſſors. Odenſee ſupplies the greateſt part of the army, and eſpecially the cavalry, with all their leather accoutrements, and is particularly famous for gloves. Here are a conſiderable cloth-manufactory, a ſugar-houſe, a manufactory for ſoap, ſeveral large breweries, corn-mills, and printing-houſes. The Daniſh language is thought to be ſpoken here in its greateſt purity. The number of inhabitants is about 5000; 17 miles from Nyeborg. N. lat. 55 4′. E. long. 10° 24′.

ODENSHOLM, a ſmall iſland in the gulf of Finland, near the coaſt of Ruſſia. N. lat. 59° 15′. E. long. 23° 15′.

ODENSWI, a town of Sweden, in Smaland; 72 miles N. of Calmar.

ODER, a river, which riſes in Moravia, about 18 miles N.E. from Olmutz, enters Sileſia and the New Mark of Brandenburg; and after paſſing by ſeveral towns, forms a large lake, called the "Friſch Haff," and ſeparating into ſeveral branches, diſcharges itſelf into the Baltic. At its mouth are two conſiderable iſlands, called Uſedom and Woldin. This river is navigable beyond Ratibor.—Alſo, a river of France, which runs into the ſea, nine miles below Quimper, in the department of the Finiſterre.

ODERBERG, a town of Brandenburg, in the Middle Mark, on the Oder; 25 miles N.W. of Cuſtrin. N. lat. 52° 56′. E. long. 14° 5′.

ODERBERG, or *Bogumin*, a town of Sileſia, in the principality of Teſchen, on the Oder; 15 miles N.W. of Teſchen. N. lat. 49° 50′. E. long. 18° 18′.

ODERLIUNGA, a town of Sweden, in the province of Schonen; 19 miles E. of Engelholm.

ODERNHEIM, a town of France, in the department of Mont Tonnerre, formerly imperial; 13 miles N.W. by W. of Worms. N. lat. 49° 45′. E. long. 8° 10′.—Alſo, a town of France, in the department of Mont Tonnerre, late in the duchy of Deux Ponts; 25 miles S.W. of Mentz. N. lat. 49° 44′. E. long. 7° 37′.

ODERQUAT, a town of the duchy of Bremen; 15 miles N. of Stade.

ODER SEIFF, a lake of Sileſia, in the principality of Breſlaw; 2 miles S. of Dyherrenfurth.

ODERZO, a town of Italy, in the Treviſan, formerly epiſcopal, the ſee of which was removed to Ceneda. It was anciently a Roman colony, called "Opiturgium," and had a port on the Adriatic, with which it communicated by the lagunes. It contains about 3400 inhabitants; 13 miles N.E. of Trevigio.

ODESCALCHI, Marc-Antonio, in *Biography*, a gentleman of Como, in the Milaneſe, embraced the eccleſiaſtical profeſſion, and was ordained prieſt. His relation, cardinal Odeſcalchi, afterwards pope Innocent XI., perſuaded him to come to Rome; but he refuſed all the honours which his own merit and family connection might have obtained for him, and devoted himſelf entirely to works of humanity. He ſought out and relieved poor families, who were aſhamed to beg; found employment for thoſe who were able to work; and took care of the ſick and infirm. He turned his own houſe into an hoſpital, for the reception of deſtitute foreigners of every nation indiſcriminately, and of the poor from the adjacent country. He himſelf waited upon, and inſtructed the objects of his charity, and not only lodged but clothed them. In theſe and ſuch like generous offices he employed himſelf till his death in 1670, and he bequeathed all his property for the maintenance of his hoſpital. The cardinal, his relation, took the inſtitution under his particular care; and when he became pope, rebuilt it magnificently, and enlarged it ſo as to contain 3000 beds. Moreri.

ODESPUN, or Odespunck, de la Mechiniere, a French prieſt, and conſiderable collector of eccleſiaſtical documents of the 17th century, was a native of Chinon in the Touraine, of the time of whoſe birth and death nothing is known. He was employed by the French clergy in forming a collection of their memoirs, which was publiſhed in two volumes, folio, in the year 1646. He alſo publiſhed "A Collection of the Councils of France, held after that of Trent," which is regarded as a decent continuation of the "Collections" of father Sirmond, in three volumes, folio; and it was ſucceeded by the "Supplement" of La Lande, in 1666. Odeſpun publiſhed alſo a work "On the Orders of Chivalry," in ſeveral volumes.

ODESSA, in *Geography*, a ſea-port town of Ruſſia, in the government of Ekaterinoſlav, on the coaſt of the Black ſea, pleaſantly ſituated near the head of a bay between the rivers Dneiper and Dneiſter, which is rendered a ſafe and convenient port, and where is formed a harbour, in which ſhips of no ſmall burden may ride ſecure from every ſtorm. A mole has been lately conſtructed, which runs nearly half a verſt into the ſea: here are other ſmaller moles, a lazaretto, &c. The roads without the port are ſafe in ſummer, and the anchorage is good. This town has ſcarcely exiſted ten years, but the population is already upwards of 10,000 perſons, and is daily increaſing. The houſes and magazines are good, and built of free-ſtone; and the ſtreets are wide, though hitherto unpaved. This place is the ſummer reſidence of the Poliſh nobility, who repair hither for the pleaſure of ſea-

bathing.

bathing. The deputy-governor of the town is an Engliſhman, formerly a merchant at Naples; and the reſident merchants are reſpectable and hoſpitable. They conſiſt of perſons from various countries. Two Engliſh houſes are eſtabliſhed here, but the principal are Germans and Italians. They carry on a very conſiderable trade. In the year 1808, it is ſaid that 1000 ſhips were loaded in this port. Wheat is the only export article, but the imports are trifling. Beſides Chriſtians, the Jews form a large part of the population. N. lat. 46° 32′. E. long. 30° 38′.

ODESTAGU, a town of Sweden, in the province of Smaland; 13 miles S.S.E. of Jonkioping.

ODEUM, ᾠδειον, among the *Ancients*, was a place deſtined for the rehearſal of the muſic to be ſung on the theatre.

Odeum was ſometimes alſo extended to buildings that had no relation to the theatre. Pericles built an odeum at Athens, where muſical prizes were contended for: Pauſanias ſays, that Herod the Athenian built a magnificent odeum for the ſepulchre of his wife.

Eccleſiaſtical writers alſo uſe odeum for the choir of a church.

ODEYGUNGE, in *Geography*, a town of Bengal; three miles N.E. of Toree. N. lat. 23° 39′. E. long. 84° 35′.

ODEYPOUR, a town of Bengal; 13 miles W. of Palamow.—Alſo, a town of Hindooſtan, capital of Juſhpour, in the ſubah of Oriſſa; 52 miles S. of Surgooja. N. lat. 22° 36′. E. long. 83° 35′.

ODHAL, or Odel's, *Right*. Pontoppidan, in his Hiſtory of Norway, p. 290, obſerves, that in the northern languages, *odh* ſignifies *proprietas*, and *all*, *totum*. Hence he derives the *odhal* right in thoſe countries, and hence perhaps is derived the *udal* right in Finland. Now the tranſpoſition of theſe northern ſyllables *allhodh*, will give us the true etymology of the *allodium*, or abſolute property of the feudiſts; as by a ſimilar combination of the latter ſyllable with *fee*, which ſignifies a conditional reward or ſtipend, *feeodh*, or *feudum*, will denote ſtipendiary property. This cuſtom, prevalent in Norway, is a right of inheritance, by which the proprietor of freeholds may repurchaſe an eſtate which either he or any of his anceſtors have ſold, provided he can prove the title of his family. In order to enforce this right, his anceſtors, and he, muſt have declared every tenth year, at the ſeſſions, that they lay claim to the eſtate, but are unable to redeem it; and whenever he, or his heirs, acquire a ſufficient ſum, then the poſſeſſor muſt, on receiving the money, relinquiſh the eſtate to the "Odel's-man." For this reaſon, the peaſants who are freeholders keep a ſtrict account of their pedigree. This cuſtom is attended with advantages and diſadvantages. It fixes the affections of the peaſant on his native place, and he improves with pleaſure thoſe poſſeſſions which are ſo ſtrongly ſecured to him, while it increaſes the conſequence and excites the induſtry of his family. On the contrary, the eſtate loſes its value when ſold to another perſon, becauſe, as the purchaſer poſſeſſes only a precarious tenure, he is not diſpoſed to improve the lands, as if he poſſeſſed the freehold. Coxe's Travels in Norway, &c. vol. v.

ODI, in *Geography*, a town of Africa, on the Slave coaſt.

ODIHAM, a ſmall market town in the hundred of the ſame name, in the Baſingſtoke diviſion of Hampſhire, England, is ſituated 24 miles from Wincheſter, and 42 miles from London. It was formerly a free borough, belonging to the biſhops of Wincheſter. The church is an ancient and ſpacious ſtructure, built of brick: and near it is an old alms-houſe. In the population ſurvey of the year 1811, Odiham is ſtated to contain 262 houſes, occupied by 1104 perſons. The poorer claſs of inhabitants are chiefly employed in ſpinning worſted and winding ſilk. At one extremity of the town is a convenient wharf, on the Baſingſtoke canal, by which all kinds of goods are conveyed to and from London. A market is held on Fridays; and here are two annual fairs. The pariſh is very extenſive, and includes ſome of the beſt arable land in this part of the county.

At North-Warnborough, about a mile from the town, are the remains of Odiham Caſtle, the origin of which was anterior to the reign of king John, when it belonged to the ſee of Wincheſter, and became celebrated for its reſiſtance againſt the army of Lewis, dauphin of France. Here David Bruce, king of Scotland, who was made priſoner at the battle of Neville's Croſs, was confined for eleven years, and then releaſed on paying 100,000 marks, and giving hoſtages for his future conduct. The original extent and form of the caſtle cannot now be aſcertained; the fragments that remain are parts of the keep, which was an octagonal building: ſome of the ditches may yet be traced.

Nearly two miles from Odiham is Dogmersfield Park, the ſeat and property of ſir H. Mildmay, bart. The manſion is an extenſive brick building, and contains ſeveral ſpacious and elegant apartments, decorated with paintings of the Italian, Venetian, and Flemiſh ſchools. In the library is a very valuable collection of books, amounting to upwards of 5000 volumes, among which is a choice ſelection of topographical works. The park includes ſeven hundred acres of diverſified ground, and is embelliſhed with ſeveral new plantations, in addition to its woods of ancient growth. Near the houſe is a piece of water of about forty-four acres. Adjoining to the park is an extenſive common, covered with oak-trees and hollies, and in many parts bearing a ſtriking reſemblance to the New Foreſt. The archbiſhops of Canterbury had a palace at Dogmersfield as early as the twelfth century. Jocelyn Fitz-Jocelyn, who was tranſlated to that ſee in 1190, died here the following year. Some extenſive foundations, ſuppoſed to belong to this building, were recently diſcovered near the preſent manſion. Beauties of England, vol. vi. by J. Britton and E. W. Brayley.

ODILO, in *Biography*, a ſaint in the Roman calendar, a celebrated abbot of Clugny in Burgundy, was the ſon of Berault, ſurnamed the *Great*, and was born at Auvergne in the year 962. When very young he was diſtinguiſhed as well by his progreſs in learning, as by his virtuous manners. Aſpiring after a life of perfection, he determined to devote himſelf to the monaſtic profeſſion; and in the year 991, after renouncing his country and relations, he took the habit in the Benedictine abbey of Clugny. Here he quickly recommended himſelf by his literary acquirements, his exact obſervance of the inſtitutions of the order, his extraordinary piety, and the ſuperiority of his mental endowments, ſo that before he had completed his probation, the abbot deſigned him for his ſucceſſor. In the year 994 this charge devolved on him, when he was only thirty-two years of age, and he performed its duties in a manner worthy of the important truſt committed to him, and that reflected the higheſt credit on his own character and the monaſtery. The whole of the time which the duties of his ſtation did not demand, he employed in devotion and ſtudy, and from what he left behind him it appears that the ſacred ſcriptures occupied a due ſhare of his attention. The reputation which the monaſtery of Clugny acquired by his diſcipline, doctrine,

doctrine, and the ſanctity of his manners, rendered it the moſt celebrated of any one in France, or any of the adjoining countries, and induced the moſt exalted perſonages to cultivate the acquaintance of the abbot. The emperor Henry, in particular, uſed frequently to ſend for him to court, in order that he and his empreſs Adelaide might be delighted and benefited by his converſation. Hugh Capet, Robert, and Henry, kings of France, ſeveral of the kings of Burgundy and Navarre, and Caſimir, king of Poland, kept up a correſpondence with Odilo, to whom they ſent frequent preſents in teſtimony of their veneration for his character. The emperor, in token of his high regard, even ſent him his crown of gold, which he ſold in a time of general and very great ſcarcity, in order to provide for the deſtitute poor. His ſpirit was, however, ſo thoroughly diſciplined to habits of virtue, that the flattering attentions of the great did not at all miniſter to his pride. On the contrary, ſo great were his modeſty and humility, that he declined accepting the archbiſhopric of Lyons, when offered him in the handſomeſt way, and preſſed upon him by pope John XIX. He died at Souvigny in 1048, in the eighty-ſeventh year of his age. This abbot was the founder of the annual ſervice of the church of Rome in commemoration of the dead. He was author of ſeveral works, particularly of the Lives of St. Mayeul; St. Adelaide the empreſs, conſort to the emperor Otho I.; Sermons; Letters, &c. His works were collected together and publiſhed by Ducheſne, in his "Bibliotheca Cluniacenſis," and thence copied into the 17th volume of the Bibliotheca Patrum. Moreri.

ODIN, in *Mythology*, called alſo in the dialect of the Anglo-Saxons *Woden*, or *Wodan*, a name given by the ancient Scythians to their ſupreme god, and aſſumed, about 70 years before the Chriſtian era, by Sigge, a Scythian prince, who conquered the northern nations, made great changes in their government, manners, and religion, enjoyed great honours, and had even divine honours paid him. According to the account given of this conqueror by Snorro, the ancient hiſtorian of Norway, and his commentator Torſæus, Odin was a Scythian, who withdrew himſelf, with many others in his train, by flight, from the vengeance of the Romans, under the conduct of Pompey: and having officiated as prieſt in his own country, he aſſumed the direction of the religious worſhip, as well as the civil government, of the nations which he conquered. Having ſubdued Denmark, Sweden, and Norway, he retired to Sweden, where he died. There is nothing certain in this account; but it is probable, that the god, whoſe prophet or prieſt this Scythian pretended to be, was named Odin, and that the ignorance of ſucceeding ages confounded the deity with his prieſt, compoſing out of the attributes of the one, and the hiſtory of the other, the character of the northern conqueror. He deluded the people by his enchantments and ſkill in magic: having cut off the head of one Mimer, who in his life-time was in great reputation for wiſdom, he cauſed it to be embalmed, and perſuaded the Scandinavians that he had reſtored it to the uſe of ſpeech; and he cauſed it to pronounce whatever oracles he wanted. The Icelandic chronicles repreſent Odin as the moſt eloquent and perſuaſive of men: they aſcribe to him the introduction of the art of poetry among the Scandinavians, and likewiſe the invention of the Runic characters. He had alſo the addreſs to perſuade his followers, that he could run over the world in the twinkling of an eye; that he had the direction of the air and tempeſts; that he could transform himſelf into all ſorts of ſhapes, could raiſe the dead, could foretell things to come, deprive his enemies, by enchantment, of health and vigour, and diſcover all the treaſures concealed in the earth. They add, that by his tender and melodious airs, he could make the plains and mountains open and expand with delight; and that the ghoſts, thus attracted, would leave their infernal caverns, and ſtand motionleſs about him. Nor was he leſs dreadful and furious in battle; charging himſelf into the ſhape of a bear, a wild bull, or a lion, and amidſt ranks of enemies committing the moſt horrible devaſtation, without receiving any wound himſelf. The era of Odin has never been ſatisfactorily aſcertained: nor is it eaſy to decide which is the moſt probable of the three ſuppoſitions reſpecting it that are extant. Gräter, with ingenious raſhneſs, ſuppoſes the iſland Sams mentioned in the Edda to be the Samos of the Archipelago; and, from ſome faint reſemblance between the Gothic coſmogony and that of a Samian philoſopher, he infers Odin to have been a pupil of Meliſſus; and thus he throws back his antiquity to a period, which would make it probable that the Scythian kings of Herodotus are the heroes deified in Gothic ſong. Mallet defends the wilder becauſe wholly baſeleſs conjecture, that the arms of Pompey occaſioned Odin to migrate from the Euxine to the Baltic. In this caſe, Pliny and Tacitus would have met with traces of his progreſs among the nations whom they deſcribe. Extenſive recent conqueſts, terminating in the impoſition of a new religion, could not but live in the memory even of barbarians. It is therefore moſt probable that Odin is poſterior to theſe writers, and that the Anglo-Saxon hiſtorians are correct, who deſcribe Hengiſt as fifth in deſcent from Odin, and who have preſerved the intervening pedigree. As in paſtoral nations marriages take place early, it is unlikely that any progenitor of Hengiſt ſhould have paſſed in celibacy his twenty-fifth year. An interval of 125 years is enough to allow between Odin himſelf and his grandſon Vecta's great-grandſon, Hengiſt. This would place Odin in the year of Chriſt 325, about 70 years before Alaric, and would plauſibly account for the momentous impulſe which, about that time, propelled the Gothic multitudes againſt all the provinces of the Roman empire.

Odin is called, in the Edda, and by Snorro, *Runhofdi* and *Runomfauthr*, father of letters, king of ſpells, as the poets phraſe it; which favours the opinion that he introduced the art of writing among the Goths. Now Tacitus expreſsly pronounces the alphabet to have been unknown to the Germans; *literarum ſecreta viri pariter ac fœminæ ignorant*: Odin, then, muſt have lived ſubſequently to this period. The oldeſt Runic inſcriptions on ſtone commemorate the fortunes of ſoldiers who had ſerved at Conſtantinople in the corps of Varangi; and the art of ſtone-cutting in the North is therefore poſterior to the transfer of the ſeat of empire from Rome to Conſtantinople. Now Odin, according to Snorro, firſt introduced the practice of uſing grave-ſtones: in his time, no doubt, they were ſimply inſcribed, not engraved: but theſe cannot long have preceded the more permanent memorials. This circumſtance, again, tends to corroborate a chronology which places Odin at the beginning of the fourth century.

There exiſts a Ruſſian map of the year 949, (the fac ſimile may be found in Schlötzer's Northern Hiſtory, p. 490.) in which the coaſt of Eſthonia is called Oſtrogard, or the *Eaſt garden*. If the oppoſite coaſt of Courland was called Aſgard, or the *Weſt garden*, the river Duna which ſeparates them may well have borne the name Mitgard. In Samo-getia, various etymological notices unite to indicate the original dwelling-place of Odin; it was natural, after his ſettlement in Upland, to ſing the "glad home" which he had forſaken; to promiſe a return thither to the ſpirits of ſuch as fell in battle; and to indicate the rainbow, which is uſually ſeen in the eaſt, as the

bridge which was to direct their path. Monthly Review, vol. xxvii. p. 382. See EDDA, and Mallet's North. Antiq. vol. i. ch. iv. and v.

ODINGTON, WALTER, in *Biography*, a monk of Eveſham, in Worceſterſhire, of whoſe writing a treatiſe is preſerved in the library of Bene't college, Cambridge, that is ſo copious and complete, with reſpect to every part of muſic when it was written; that if all other muſical tracts, from the time of Boethius to Franco and John Cotton, were loſt, our knowledge would not be much diminiſhed, if this MS. was acceſſible.

The ingenious author of this work was eminent in the early part of the thirteenth century, during the reign of Henry III. not only for his profound knowledge in muſic, but aſtronomy, and mathematics in general. The tranſlator and continuator of Dugdale's Monaſticon, ſpeaks of him among learned Engliſhmen of the order of St. Benedict in the following manner:

"Walter, monk of Eveſham, a man of a facetious wit, who applying himſelf to literature, leſt he ſhould ſink under the labour of the day, the watching at night, and continual obſervance of regular diſcipline, uſed at ſpare hours to divert himſelf with the decent and commendable diverſion of muſic, to render himſelf the more chearful for other duties." This apology, however, for the time he beſtowed on muſic, was needleſs; for it was, and is ſtill, ſo much the buſineſs of a Romiſh prieſt, that to be ignorant of it diſqualifies him for his profeſſion. And at all times, where an eccleſiaſtic thought it neceſſary to trace the whole circle of the ſciences, muſic having the ſecond or third rank, could not be neglected. But what this author adds farther concerning Odington is ſtill leſs defenſible: "Whether," ſays he, "this application to muſic drew him off from other ſtudies I know not, but there appears no other work of his than a piece entitled "Of the Speculation of Muſick." Yet we are told by Pits, Bale, Tanner, Moreri, and all his biographers, that he wrote "De Motibus Planetarum, et de Mutatione Aëris," as well as on other learned ſubjects. As Walter of Eveſham lived at a period which furniſhes but few records concerning the ſtate of muſic in England; and as we are acquainted with no other copy of his MS. than that which is preſerved at Cambridge, we ſhall be ſomewhat the more minute in deſcribing its contents, and pointing out its peculiarities.

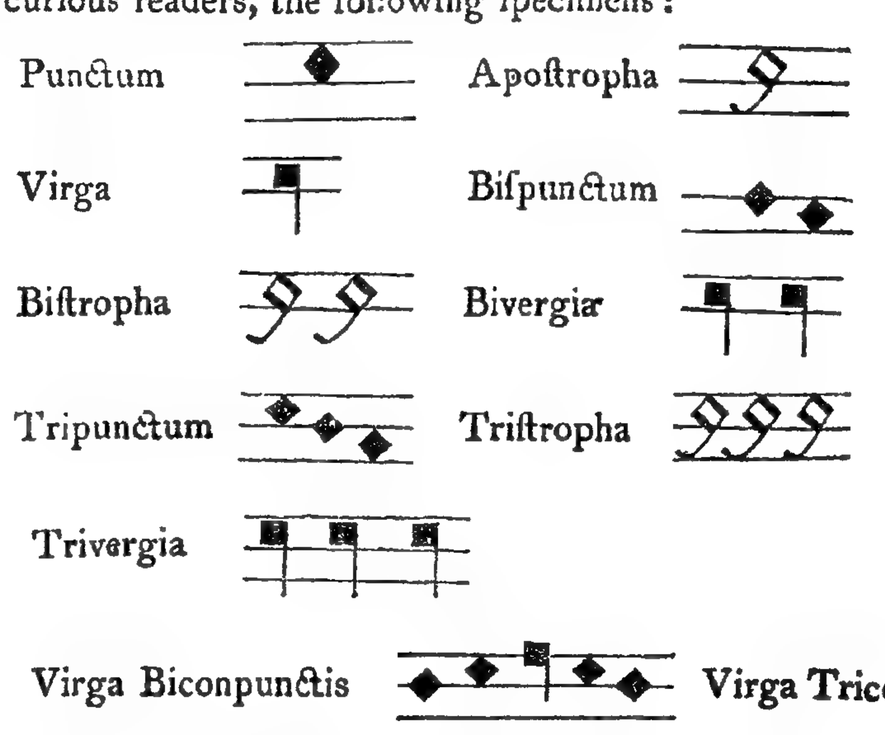
The firſt page, only, has been injured by time, and ſome vacuities have been left by the ſcribe, which ſeem intended to have been filled up with red ink. The work is divided into ſix parts, or books.

The firſt, "De Inequalitate Numerorum et eorum habitudine," contains ten chapters, on the diviſion of the ſcale, and harmonical proportions.

The ſecond part conſiſts of eighteen chapters. In the introduction to this part he calls the concords *ſymphonies*, which is frequently the language of Hubald, Odo, and Guido. The firſt chapter is an "Eulogium upon Muſic," in which he enumerates the nine Muſes and their attributes; ſpeaks of David's power over the evil ſpirit of Saul, by means of his harp; quotes Clemens Alexandrinus, but not in Greek; and after giving the invention of inſtruments to Tubal, relates the manner in which Pythagoras diſcovered harmonical proportions by the weights of a blackſmith's hammers. Speaks of major and minor ſemitones, and of the comma. He has a long chapter on the proportions of the major and minor thirds: here he takes occaſion to deſcribe the different kinds of human voices, from the ſhrill cries of the infant to the deep and dying groans of an old man; but mentions not thoſe of the *evirati*. Accounts for the thirds having been regarded as diſcords by the ancients who adhered to the proportions of Pythagoras; and ſays, that to pleaſe in harmony they muſt neceſſarily be altered, or, as it was afterwards called, *tempered*. In his ſeventeenth chapter he gives a liſt of concordant diſcords, *concordes diſcordiæ*, or the leſs perfect double ſounds; and theſe he ſays are ſix: the minor and major third; the *diapente cum tono*, or major ſixth; the two tenths, or octaves of the thirds; and the diapaſon and diateſſaron, or eleventh.

The third part is chiefly ſpeculative, and confined to harmonics: forming the ſcale, and dividing the monochord, by numbers, and giving rules for the proportions of organ pipes, and the caſting of bells. He ſpeaks of the three kinds of melody, "De tribus generibus Cantilenæ;" and after deſcribing the diatonic, chromatic, and enharmonic of the ancients, he ſupports his opinions by the authority of Nicomachus. Greek muſical authors, or at leaſt their doctrines and technical terms, ſeem familiar to Odington, who quoted the firſt book of Euclid at the beginning of his work, and in this third part he gives the characters and names of the notes in the Greek ſcale, and tranſlates them into the ſame language as Martianus Capella and Boethius. In his chapter "De Organis componendi," he gives a diagram of numbers and intervals, in naming which by the letters of the alphabet he begins with the Greek Γ, and goes on from A to S. At the ſide of the diagram he mentions the Greek names of the ſeveral tetrachords and conſonances; with the numbers, tones, and ſemitones. All this is manifeſtly for the proportions of pipes in the inſtrument called an *organ*, not the *organum*, or ſecond voice part in diſcant, of which he treats in his laſt book, as will appear farther on. This, and his chapter "De Cymbalis faciendis," or caſting of bells, are curious, and the firſt inſtructions of the kind that we have ever ſeen among the MSS of the middle ages.

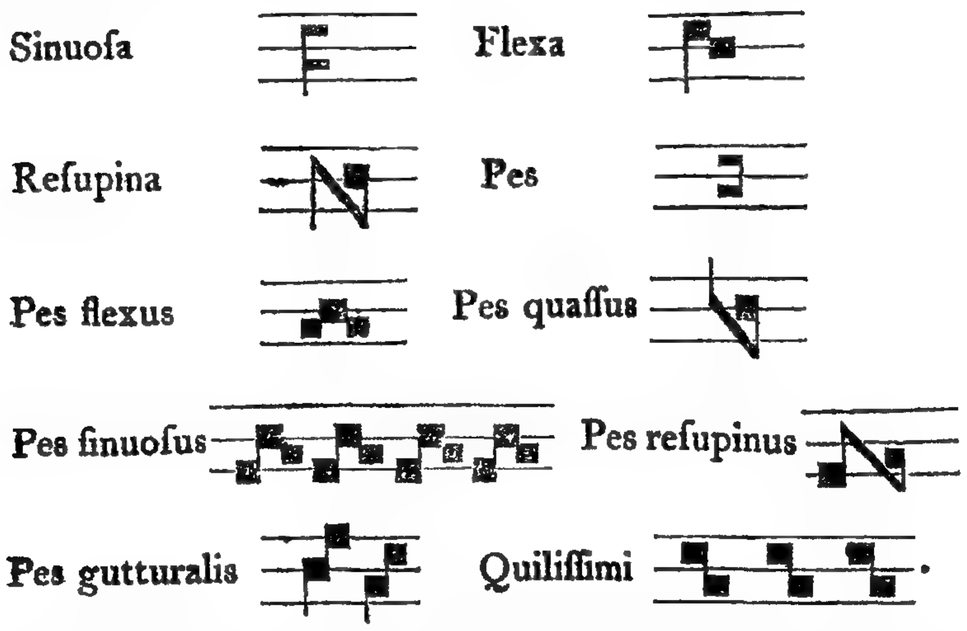
Names and figures occur in this work of ſuch notes as were in uſe in the Weſtern church before the invention of lines, many of which were not merely characters to expreſs the elevation and depreſſion of ſounds, but, according to Odington, theſe characters extended their import to the inflections of the voice in almoſt every ſpecies of interval, while groups of notes were expreſſed by a ſingle term of art; and as but few ſuch characters and technical terms occur in any other author, we ſhall inſert, for the ſatisfaction of curious readers, the following ſpecimens:



punctis—condiateſſaries, condiapentis, &c. &c. He gives examples of all theſe in ſimilar characters; that is, in breves with a long, as far as ſix notes, or a hexachord aſcending and deſcending, but without calling them by thoſe names.

The

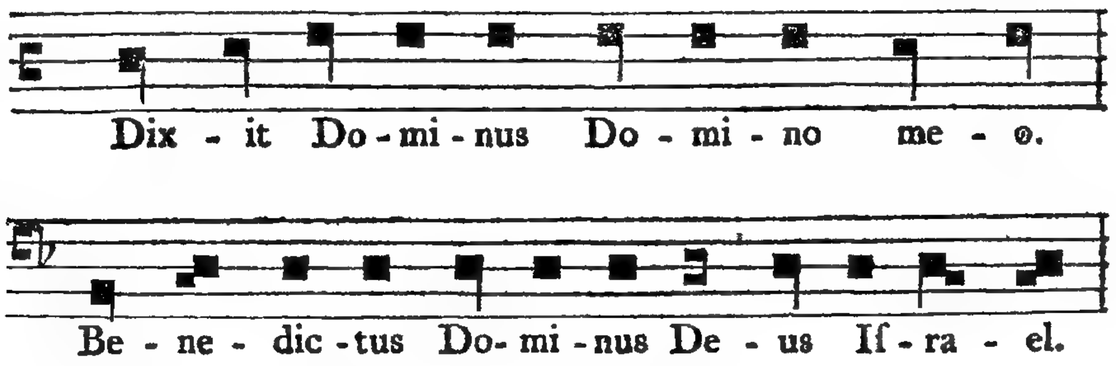
The following are characters to expreſs wider intervals, and ſhort paſſages:



He has many more, which ſeem never to have been adopted by ſucceeding writers.

After explaining theſe characters, he ſpeaks of the modern expedient of naming the ſounds from the ſyllables of the hymn "Ut queant laxis," &c. but without mentioning Guido. Then gives the great ſyſtem or ſcale in ſeptenaries, after Guido's manner, in capital, ſmall, and double letters. Here he ſpeaks of *voces mobiles* in the ancient manner, and of F quadrata, as uſed in *muſica falſa*, or tranſpoſitions, not, ſays he, "per diſſonem, ſed extranea et apud antiquos inuſitata." Then he has a chapter "De Mutationibus," in which he explains the change of names in ſolmiſation in the ſame manner as was done by ſucceeding writers long after his time.

The reſt of this book is employed in deſcribing different kinds of eccleſiaſtical chants, and in giving rules for compoſing them. Then dividing the modes into authentic and plagal, he gives examples of canto fermo, which ſeem more florid than appear in miſſals of the ſame period. The two following intonations, which he gives upon five lines, will ſerve as ſpecimens:



The *euouae*, initials, and finals of all the modes, are given in this kind of notation very amply, and always on five lines, and ſpaces. At the beginning of the laſt chapter of this book the words *Ananes*, *Neanes*, *Nana*, &c. uſed by Odo and the modern Greeks in their intonations, occur. This ſeems the moſt complete deſcription and notation of the eccleſiaſtical chant that we have found in any author of equal antiquity.

In the ſixth and laſt part, beſides the "Cantus Menſurabilis," he treats "De Generibus Cantuum Organorum, et de Compoſitione Cantuum Organorum," of organizing chants, or the compoſition of organic or ſecond parts to chants: and firſt, "De Organo Puro." Here we meet with all the technica of later times, as tenor, motetus, coloratus, cantilena, and rondellus. The muſical examples, however, as uſual in old manuſcripts, are incorrect, and frequently inexplicable, owing to the ignorance of muſic in the tranſcribers; but if this tract were corrected, and ſuch of the examples as are recoverable, regulated and reſtored, it would be the moſt ample, ſatisfactory, and valuable, which the middle ages can boaſt; as the curious enquirer into the ſtate of muſic at this early period may diſcover in it not only what progreſs our countrymen had made in the art themſelves, but the chief part of what was then known elſewhere.

ODIO *& Atia*, anciently called *breve de bono & malo*, in *Law*, is a writ directed to the ſheriff, to enquire whether a man, being committed to priſon on ſuſpicion of murder, be committed on juſt ſuſpicion, or only malice, and ill will.

ODIR, in *Geography*, a ſmall iſland in the Eaſt Indian ſea, near the W. coaſt of Aroo. S. lat. 5° 23′. E. long. 134° 58′.

ODNESS, a cape of Scotland, on the E. coaſt of the iſland of Stronſa. N. lat. 58° 59′. W. long. 2° 26′.

ODO, in *Biography*, a Romiſh ſaint and abbot of Clugny in the 10th century, was of noble deſcent, and born in the country of Maine, in the year 879. At the age of nineteen he was made canon of St. Martin's, at Tours, after which he went to Paris, and became a diſciple of St. Remi of Auxerre. Having reſolved to embrace the monaſtic life, he, in 912, took the habit in the monaſtery of Baume, in the dioceſe of Beſançon, where he was diſtinguiſhed by the practice of the moſt auſtere exerciſes of the cloiſter, and applied very earneſtly to the acquiſition of ſuch learning as the ignorance of the times permitted. He was appointed to preſide over the ſchool of the monaſtery, and in 926 he received prieſts' orders, and in the following year, upon the death of Berno, firſt abbot of Clugny, he was elected ſucceſſor in that dignity. At this period the Latin monks had loſt ſight of all ſubordination and diſcipline, and Odo ſet himſelf to correct abuſes. He not only obliged the monks to live in the regular obſervance of their rules, but alſo added to their diſcipline new rites and ceremonies, which were attended with an air of ſanctity, and which were ſevere and burthenſome. The fame of this new rule of diſcipline ſoon ſpread over Europe, and it was adopted in the greateſt part of the ancient monaſteries which had been founded in France, Germany, Italy, Britain, and Spain, as well as in the convents which had been newly eſtabliſhed. So high was Odo's reputation for wiſdom and ſanctity, that the popes, the biſhops, and the ſecular princes, paid the utmoſt deference to his counſels, and frequently conſtituted him arbiter of their diſputes. In 936 he took a journey, and was ſucceſsful in mediating a peace between Alberic, prince of Rome, and Hugh, king of Italy. Two years after this he went, a ſecond time, to Rome, and by his influence with Hugh, prevailed upon him to withdraw from the ſiege of the city. In 942 he made a third viſit to Rome, purely on religious motives, and while he was in that city he was attacked by a ſevere diſorder, which obliged him to haſten back to France. He died at Rheims, in the

ſixty

ſixty-fourth year of his age. He was author of ſeveral works, which are collected in the 17th volume of the Bibl. Patrum. Moreri.

Mabillon (Acta Sanct. ord. 5. Bened. tom. vii. p. 126.) ranks Odo at the head of literature and the polite arts at the beginning of the tenth century. He ſtudied under St. Remi, at Paris, and, among other ſciences, applied himſelf ſo ſucceſsfully to muſic, that he was afterwards regarded as the moſt learned muſician of his time. He made three ſeveral voyages to Rome, in 936, 938, and 942, where, it is natural to ſuppoſe, he acquired a perfect knowledge of the Gregorian chant, and was initiated in all the refinements that were then practiſed in St. Peter's church and the pontifical chapel.

Some of his hymns, chants, and anthems, are ſtill preſerved in the Romiſh church; and there are two copies of a MS. tract upon muſic, of his writing, in the king of France's library at Paris. They are in ſeparate volumes, and both bound up with many other ancient muſical treatiſes. There is a tract of great antiquity in the library of Baliol college, Oxford, which, by the initial ſentence "Quid eſt muſica?" we once imagined to have been written by Odo; but are now convinced that it is the work of Guido himſelf: for, in carefully peruſing, and collating it with the extracts we had made from the Enchiridion of Odo, in the libraries of the late king of France, and elſewhere, as well as with the quotations from it in the Muſical Hiſtories of P. Martini, and the prince Abbot Gerbert, we find it to be totally a different work, agreeing in nothing but the initial queſtion. But the moſt beautiful and perfect copy which we have ſeen, and which perhaps can now be found of the ſcarce and curious tracts upon muſic, by the venerable monk Hubald, of St. Amand, and St. Odo, abbot of Cluny, ſubſiſt in the library of Bene't college, Cambridge.

We come now to the celebrated Enchiridion of Odo, which is written in dialogue, and mentioned with reſpect, even by Guido himſelf. "Incipit Scholium Enchiridij de Arte Muſica." The dialogue is between a maſter and his diſciple.

The diagrams and muſical examples are all given in the ſame characters as thoſe of Hubald. His doctrine of the tones, or eccleſiaſtical modes, is illuſtrated by innumerable ſpecimens in this kind of notation.

In this treatiſe, the barbarous and unmeaning words, in Gothic letters, occur, which the Greek church uſed during the ninth, tenth, and eleventh centuries, to characteriſe the modes or tones: *Nonanoeane*, *Noeane*, *Noioeane*, *Anoais*. The terms like theſe are ſtill retained by the modern Greeks in their eccleſiaſtical muſic, as we find by Leo Allatius, and by the Abate Martini's papers.

The entablature, or notation of Hubald and Odo, very much reſemble each other, as does their counterpoint; indeed theſe eccleſiaſtics were not only contemporaries and friends, but diſciples of Remi, monk of St. German d'Auxerre; and Odo, the youngeſt of the two, ſurvived Hubald but twelve years.

The firſt part of this tract ends thus: "Præterea et grata ſymphoniarum commixtio maximam ſuavitatem cantilenis adjicet."

And in the ſecond part he proceeds to the explanation of this extraordinary ſymphonic ſweetneſs; which, he tells his diſciple, conſiſts in the pleaſing mixture of certain ſounds, ſuch as the octave, 5th, 4th, &c.

Then follow examples of organizing in all his ſix concords, which are only thoſe of the ancients, 4th, 5th, 8th, 11th, 12th, and 15th; and in giving an example in four parts, where he doubles the organum and principal part to theſe words, *Nos qui vivimus*, they move conſtantly in theſe intervals, uniſon, 4th, 8th, and 11th.

The author next proceeds to give the ratio of ſounds, and to ſhew the alliance between muſic and mathematics, calling arithmetic the mother of muſical tones.

He afterwards treats of the proportions of flutes or muſical pipes, to which he applies his harmonics.

The laſt chapter is a ſummary of the tones or modes of canto fermo; and here, as elſewhere, his examples are always in the ſame hieroglyphic notation: NO *J* A *F* NO *If* E *F* A *If* NE—&c.

This laſt chapter is not quite perfect; the tranſcriber having omitted ſome of the muſical examples and diagrams. Only ſix of the eight modes are finiſhed. The ſeventh, however, is begun, and not more than one, or two pages at moſt, can be wanting to complete theſe two ſcarce and valuable relics of the firſt eſſays at modern harmony; which, however rude, uncouth, and barbarous, continued in the church, without offending Chriſtian ears, for more than three centuries: for the monk Engelbert, who, in the latter end of the thirteenth century, at the inſtigation of his friends, wrote a treatiſe on muſic, tells us, that all regular diſcant conſiſts of the union of 4ths, 5ths, and 8ths.

It has already been ſhewn that this kind of harmony, miſerable and nauſeous as it would be to our palates, did not offend Guido; on the contrary, he recommends the regular ſucceſſion of fourths above all other concords, to excite and expreſs pleaſure and jubilation. Nor do any advances or attempts at variety ſeem to have been made in counterpoint from the time of Hubald to that of Guido: a period of more than a hundred years.

Indeed it is hardly poſſible to examine the laſt ſpecimen of Hubald's counterpoint, without being aſtoniſhed that no advances had been made in the art for a whole century; for, with all its faults and crudities, it is at leaſt equal to the beſt combinations of Guido. But perhaps Hubald's inventions or improvements never eſcaped the confines of his convent, or at moſt, were only publiſhed in his own dioceſe; and, like the propoſals of other ingenious men, whoſe views are extenſive, and who anticipate future diſcoveries, they were not adopted or reduced to practice in his life-time. His idea that one voice might wander at pleaſure through the ſcale, while the other remains fixed, ſhews him to have been a man of genius and enlarged views, who diſregarding rules, could penetrate beyond the miſerable practice of his time into our *points d'orgue*, *pedalè*, and multifarious harmony upon a holding note or ſingle baſe, and ſuggeſt the principle, at leaſt, of the boldeſt modern harmony. Odo is the only one of his contemporaries, or ſucceſſors, whoſe writings have come to our knowledge, that has imitated his notation.

ODOACER, firſt barbarian king of Italy, was the ſon of Edecon, a chieftain of the tribe of the Scyrri, who had been in the ſervice of Attila, king of the Huns. After the death of his father, and the diſperſion of his nation, Odoacer for ſome time led a wandering life among the barbarians of Noricum, with a mind and fortune ſuited to the moſt deſperate adventures; and when he had fixed his choice, he viſited the cell of Severinus, the popular ſaint of the country, to ſolicit his approbation and bleſſing. The lowneſs of the door would not admit the lofty ſtature of Odoacer: he was obliged to ſtoop, but in that attitude the ſaint could diſcern the ſymptoms of his future greatneſs, and addreſſing him in a prophetic tone, he ſaid, "Purſue your deſign; proceed to Italy; you will ſoon caſt away this coarſe garment of ſkins,

and your wealth will be adequate to the liberality of your mind." He accepted and ratified the prediction, was admitted into the ſervice of the weſtern empire, and ſoon obtained an honourable rank in the guards. In the year 476, the barbarian mercenaries in the Roman army demanded a third part of the lands of Italy as a reward for their ſervices, which the patrician Oreſtes refuſing to grant, they unanimouſly placed at their head Odoacer, and proclaimed him their king. He marched againſt Oreſtes, took him priſoner, and put him to death: he next depoſed Auguſtulus, the ſon of Oreſtes, who had been placed on the imperial throne of the weſt by his father, and who was the laſt that poſſeſſed that title. Odoacer ſpared him on account of his youth, but aſſumed the government of Italy with the title of king; he abſtained during his whole reign from the uſe of the purple and the diadem, leſt he ſhould give offence to thoſe princes, whoſe ſubjects, by their accidental mixture, had formed the victorious army, which time and policy might inſenſibly unite into a great nation. "Royalty," ſays the hiſtorian, "was familiar to the barbarians, and the ſubmiſſive people of Italy were prepared to obey, without a murmur, the authority which he ſhould condeſcend to exerciſe as vicegerent of the emperor of the weſt. But Odoacer had reſolved to aboliſh that uſeleſs and expenſive office, and ſuch is the weight of antique prejudice, that it required ſome boldneſs and penetration to diſcover the extreme facility of the enterprize. The unfortunate Auguſtulus was made the inſtrument of his own diſgrace; he ſignified his reſignation to the ſenate, and that aſſembly, in their laſt act of obedience to a Roman prince, ſtill affected the ſpirit of freedom, and the forms of the conſtitution." The preciſe year in which this event of the extinction of the weſtern empire took place is not aſcertained, but it was ſome time between the years 476 and 479. Odoacer appears to have conducted himſelf in the exerciſe of his authority with more juſtice and moderation, than might have been expected from one who roſe to power by ſuch means as he had adopted. He reſpected the ancient laws and inſtitutions of the country, and cauſed juſtice to be ſtrictly adminiſtered. After an interval of ſeven years he reſtored the conſulſhip of the weſt. He protected the confines of Italy by his arms, croſſed the Adriatic to take poſſeſſion of Dalmatia, and conquered the king of the Rugians in the province of Noricum. Notwithſtanding the prudence and ſucceſs of Odoacer, his kingdom exhibited the melancholy proſpect of miſery and deſolation. Since the age of Tiberius, the decay of agriculture had been felt in Italy, and it was a ſubject of juſt complaint, that the exiſtence of the Roman people depended on the accidents of the winds and waves. The number of the inhabitants continually diminiſhed with the means of ſubſiſtence, and the country was exhauſted by the irretrievable loſſes of war, famine, and peſtilence. In this ſtate of things, the famous Theodoric, king of the Oſtrogoths, was perſuaded, by the emperor Zeno, to turn his arms againſt the king of Italy: he ſucceeded in his attempt, and overcame him in three obſtinate engagements; and in the laſt he was obliged to make propoſals for accommodation, which were readily liſtened to. This was at Ravenna, the biſhop of which city negociated a peace between the two kings, and it was agreed, under the ſanction of an oath, that they ſhould rule with equal and undivided authority the provinces of Italy. After ſome days had been devoted to the ſemblance of joy and friendſhip, Odoacer, in the midſt of a ſolemn banquet, was ſtabbed by the hand, or at leaſt by the command, of his rival, and at the ſame time all his officers and mercenaries were maſſacred. This event happened in March 493. Univer. Hiſt. Gibbon.

ODOEV, in *Geography*, a town of Ruſſia, in the government of Tula, on the Upha; 52 miles W. of Tula. N. lat. 53° 50′. E. long. 36° 14′.

ODOLI-HOTUN, a town of Chineſe Tartary. N. lat. 43° 32′. E. long. 127° 38′.

ODONTAGNATHUS, in *Ichthyology*, a genus of fiſhes of the order Apodes. The generic character is as follows: mouth furniſhed with ſtrong, moveable laminæ, or proceſſes on each ſide the upper jaw; the gill-membrane is five-rayed. There is but a ſingle

Species.

ACULEATED. This derives its ſpecific name from the aculeated abdomen. The genus was inſtituted by La Cépéde, whoſe deſcription is as follows. The head, the body, and tail, are very compreſſed; the lower jaw is longer than the upper, and is much elevated towards the other when the mouth is cloſed, ſo as to appear almoſt vertical, and is lowered ſomewhat in the manner of a drawbridge, when the mouth is opened; it then appears like a ſmall ſcaly boat very tranſparent, furrowed beneath, and finely denticulated on the margins. This lower jaw, in the act of depreſſion, draws forwards two flat, irregular laminæ of a ſcaly ſubſtance, a little bent at their poſterior end, and larger at their origin than at the tips, denticulated on their anterior margin, and attached, one on one ſide, and the other on the oppoſite, to the moſt prominent part of the upper jaw; in the middle of the jaws is placed the tongue, which is pointed and free in its movements: the gill-covers, which are compoſed of ſeveral pieces, are very tranſparent at the hind part, but ſcaly, and of a bright ſilver-colour in front; the gill-membrane is alſo ſilvery, and has five rays; the breaſt is terminated below by a ſharp carina, furniſhed with twenty-eight ſpines, diſpoſed in two longitudinal ranges; the anal-fin is very long, and extends almoſt as far as the baſe of the tail-fin, which is of a forked ſhape; the dorſal-fin is placed on the tail, properly ſpeaking, at about three quarters of the whole length of the animal, but it is extremely ſmall. The colour is ſuppoſed to be of a bright ſilver, from the ſpecimens preſerved ſome time in ſpirits. It is a native of the American ſeas, and is common about the coaſts of Cayenne, where it is ranked as a ſpecies of food.

ODONTAGOGOS, from οδους, *a tooth*, and αγω, *to draw*, in *Surgery*, an inſtrument for drawing teeth.

ODONTAGRA, from οδους, *a tooth*, and αγρευω, *to ſeize*, an inſtrument for drawing teeth. Alſo gouty pain in the teeth.

ODONTALGIA, from οδους, *a tooth*, and αλγος, *pain*, the tooth-ache. See TOOTH-ACHE.

ODONTIASIS, from οδοντιαω, *to cut the teeth*; dentition.

ODONTICA, from οδους, remedies for the tooth-ache.

ODONTIRRHŒA, from οδους and ῥεω, *to flow*, bleeding from the ſocket, after the extraction of a tooth.

ODONTISME, in the *Muſic of the Ancients*, made, according to Jul. Pollux, a part of the Iambic and a third part of the Pythian nome.

ODONTITES, in *Botany*, ſo called from οδους, οδοντος, *a tooth*, a plant mentioned by Pliny as "a ſort of hay, with ſmall denſe, or crowded, ſtems from the ſame root, which are jointed, triangular, and black. It has ſmall leaves at the joints, but longer than thoſe of *Polygonum*. Seeds axillary, reſembling barley. Flower purple, ſmall. It grows in meadows. A decoction of a handful of the ſtalks in wine of a rough flavour, held in the mouth, cures the tooth-ache." Botaniſts have preſumed the above deſcription to apply to the *Lychnis Flos Cuculi*, ſome latitude being allowed for what concerns the ſeeds. Linnæus has followed

Tabernæ-

Tabernæmontanus, in taking a ſpecies of *Euphraſia*, or *Bartſia* of *Fl. Brit.*, for the *Odontites*, and has retained this word as its ſpecific name. Pliny's deſcription, ſuch as it is, agrees beſt with the above *Lychnis*, whoſe very remarkably toothed petals, might almoſt induce a ſuppoſition that the ancients were led in this inſtance, as in ſome others, to judge of the virtues of plants by their ſhape or ſtructure. On this ground the Orchis roots have been thought aphrodiſiac, and plants with oblong tuberous roots, good for the piles! We know not that any particle of truth has been ſtumbled upon by this ſagacious mode of inveſtigation; for where there may happen to be any ſuch coincidence, the qualities of the plants were all, if we miſtake not, previouſly known. The only famous writer on this ſubject, and one is ſurely enough, is Giovanni Baptiſta Porta, a Neapolitan, who in the latter part of the ſixteenth century collected all that can be ſaid about it, and certainly much more than is worth reading.

ODONTOGLYPHON, from οδους, and γλυφω, *to ſcrape*, in *Surgery*, an inſtrument for ſcraping the tartar off the teeth.

ODONTOIDES, in *Anatomy*, from οδους, οδοντος, *a tooth*, and ειδος, *form*, a name given to a proceſs of the ſecond vertebra of the neck. See SPINE.

ODONTOPHYIA, from οδους and φυω, *to grow*, in *Surgery*, the proceſs by which the teeth are firſt formed: dentition.

ODONTOTRIMMA, from οδους, and τριβω, *to wear away*, a dentrifice, or application for cleaning the teeth.

ODOR, or ODOUR. See SMELL, and NOSE.

ODORAMENTUM, in *Pharmacy*, a medicine applied for the benefit of its ſmell, whether it be fetid, or agreeable.

Such are frequently uſed in hyſteric and hypochondriac diſorders; *e. gr.* aſſafœtida, camphor, &c.

ODORIFERÆ, in *Anatomy*, certain glands belonging to the male organs of generation. See GENERATION.

ODOROUS, or ODORIFEROUS *Things*, are ſuch as exhale a briſk, agreeable ſmell, ſenſible at a diſtance.

Such are the jeſſamin, roſe, tuberoſe, &c.

ODOVARA, in *Geography*, a ſea-port town of Japan, in the iſland of Niphon; 120 miles E.N.E. of Meaco.

ODRAU, a town of Sileſia, in the principality of Oppau, near the Oder; 32 miles W.S.W. of Teſchen.

ODYSSEY, ODYSSEA, formed from Οδυσεια, which ſignifies the ſame with Οδυσσευς, *Ulyſſes*, an *epic* poem of Homer, wherein he relates the adventures that befel Ulyſſes in his return to Ithaca from the ſiege of Troy.

The deſign of the Iliad, F. Boſſu obſerves, is to inſtruct the ſtates of Greece, conſidered as united in one body, or as parts of the whole; and that of the Odyſſey, to inſtruct thoſe ſame ſtates, conſidered in their private capacities.

A ſtate conſiſts of two parts: the head, which commands, is the firſt; and the members, that obey, the ſecond. Now, inſtructions are required both for the one and the other; but it is poſſible to have them both conveyed under the ſame perſon.

The fable, then, of the Odyſſey is as follows. A prince had been obliged to quit his country, and lead an army of his ſubjects upon a foreign expedition. After having glorioufly executed this, he was upon his return home; but in ſpite of all his endeavours, was detained for ſeveral years by tempeſts, which threw him on ſeveral countries very different from one another as to manners, cuſtoms, polity, &c.

In the dangers he had to ſtruggle with, his companions, neglecting his advice, all periſhed through their own default. In the mean time, the great men of his country, abuſing his abſence, commit ſtrange diſorders in his palace, ſquander his treaſure, lay ſnares for his ſon, and would force his wife to chooſe a huſband among them; all this from an opinion, that he was entirely loſt. But at length he returns; and having diſcovered himſelf to his ſon, and ſome others of his friends who had perſiſted in their allegiance, he becomes an eye-witneſs of the inſolence of his courtiers; puniſhes them as they deſerved; and reſtores that peace and tranquillity to his iſland, which had been baniſhed during his abſence.

The truth or model on which this fable is founded is, that a perſon's abſence from home, ſo that he cannot have an eye to his affairs, occaſions great diſorders. Accordingly, the hero's abſence is the principal and moſt eſſential part of the action, and takes up the greateſt part of the poem.

This poem, Boſſu adds, is more calculated for the people than the Iliad is, where the ſubjects ſuffer rather from the ill conduct of their princes than by their own faults. The great names of heroes, Ulyſſes, &c. do not here repreſent the pooreſt peaſants leſs than princes, Cæſars, Alexanders, &c. The meaneſt people are as liable to ruin their eſtates and families by negligence, &c. as the greateſt; and accordingly have as much need of Homer's lectures, and are as capable of profiting by them, as kings themſelves.

Dr. Blair obſerves, that Longinus's criticiſm on the Odyſſey is not unfounded; *viz.* that Homer may in this poem be compared to the ſetting ſun, whoſe grandeur ſtill remains, without the heat of his meridian beams. It wants the vigour and ſublimity of the Iliad; and yet poſſeſſes ſo many beauties as juſtly to entitle it to high praiſe. It is a very amuſing poem, and has much greater variety than the Iliad: its numerous ſtories are intereſting, and its deſcriptions are beautiful. The ſame deſcriptive and dramatic genius, and the ſame facility of invention that appear in the Iliad, are manifeſt in the Odyſſey. Although it deſcends from the dignity of gods and heroes, and warlike achievements, it nevertheleſs affords more pleaſing pictures of ancient manners. Inſtead of the ferocity that reigns in the Iliad, the Odyſſey preſents us with the moſt amiable images of hoſpitality and humanity, entertains us with many wonderful adventures, and inſtructs us by a conſtant vein of morality and virtue, which runs through the poem. The Odyſſey, however, has acknowledged defects. Many of its ſcenes fall below the majeſty expected in an epic poem. The laſt 12 books, after Ulyſſes is landed in Ithaca, are, in ſeveral parts, tedious and languid; and though the diſcovery which Ulyſſes makes of himſelf to his nurſe Euryclea, and his interview with Penelope before ſhe knew him, in the 29th book, are tender and affecting, yet the poet does not ſeem happy in the anagnoriſis or the diſcovery of Ulyſſes to Penelope; ſhe is too cautious and diſtruſtful, and we are diſappointed of the ſurpriſe of joy, which we expected on that high occaſion. Blair's Lect. vol. iii.

Gerard Croes, a Dutchman, in a book entititled Ομηρος Εβραιος, printed at Dort, in 1704, endeavours to prove, that the ſubject of Homer's two poems are taken from the Scriptures; that the action of the Odyſſey, in particular, is nothing elſe but the adventures of the Iſraelites till the death of Moſes; and that the Odyſſey was compoſed before the Iliad, the ſubject whereof is the taking of Jericho. What fancies!

OE, in *Geography*, a ſmall iſland of Denmark, N. of Laland. N. lat. 54° 58′. E. long. 11° 31′.

OEBSFELD, a town of Weſtphalia, in the duchy of Magdeburg, on the Aller; 30 miles N.W. of Magdeburg.

ŒCOLAMPADIUS, called in his own country HAUKSCHEIN, JOHN, in *Biography*, one of the moſt learned German reformers in the 16th century, was born at Winſperg, a village in Franconia, in the year 1482. He was educated with a view to ſome learned profeſſion, and was, when he had made conſiderable progreſs in grammar-learning, ſent to the univerſity of Heidelberg, where he was admitted to the degree of bachelor of philoſophy when only fourteen years of age. As ſoon as he had taken the degree of M. A. his parents ſent him to Bologna in Italy, with a view to his ſtudying the law under the celebrated profeſſors of juriſprudence, for whom that univerſity was in high repute. After the end of ſix months he returned to Heidelberg, where he gave up all thoughts of ſtudying the law as a profeſſion, and applied himſelf to theology. His object was very different from the uſual courſe purſued at that period; inſtead of aiming at the glory of excelling as a diſputant in the public exerciſes of the univerſity, his chief ambition was to ſtore his mind with valuable and uſeful knowledge. One of his earlieſt ſteps in life was that of becoming tutor to the children of Philip, elector palatine, but Œcolampadius ſoon became diſguſted with the manners of the court, relinquiſhed his charge, and reſumed with freſh ardour his theological ſtudies. Having finiſhed the uſual academical ſtudies, he quitted the univerſity, and having received prieſt's orders, he entered upon a living at Winſperg, his native place, which had been endowed by his father. He had not officiated many weeks, when a diffidence in his own talents and qualifications led him to obtain leave to go to Stutgard for further improvement, where he attended the lectures of the learned Reuchlin, and perfected himſelf in the Greek and Hebrew languages. After this he returned to his benefice, and was diſtinguiſhed by the great zeal and diligence with which he performed the ſeveral duties attached to the paſtoral offices. During the reſidence of Œcolampadius at the univerſity of Heidelberg, he had contracted an intimacy with Wolfgang Capito, who was now ſettled at Baſil, and who obtained for his friend an invitation from the biſhop of Baſil to become a preacher in that city, and upon his arrival the prelate appointed him to the duties of the principal church. This was in the year 1515, and in the following year, when Œcolampadius was about thirty-four years of age, he took his degree of D. D. At this period Eraſmus came to Baſil to print his "Annotations on the New Teſtament," in which work he was aſſiſted by Œcolampadius, who, in a ſhort time, was invited to ſettle at Augſburg, where he preached in the great church, but finding a ſtrong leaning towards the principles of the reformation, and not having courage to riſk the conſequences of ſuch a change in his opinions, he entered the monaſtery of Alton, in the neighbourhood of Augſburg, to avoid being queſtioned on the ſubject. His friends greatly diſapproved of this ſtep, urged him to quit the monaſtery, and a regard to his private ſafety led him, at length, to comply with their ſolicitations. He had already given his private opinion in favour of the reformers, and had by his publications, particularly one on "Confeſſion," given a ſtrong handle to his enemies, of whom John Glaſſio, a Franciſcan, and chaplain to Charles V., projected the deſign of taking him into cuſtody, and holding him up as an example of ſignal puniſhment; he had, however, information of their deſign three days before it was to be put into execution, and by this he was enabled to retire out of the reach of his enemies. Having arrived in ſafety at Baſil in 1522, he applied himſelf to the tranſlation into Latin of St. Chryſoſtom's "Commentary upon the Book of Geneſis." He was almoſt immediately appointed profeſſor of divinity by the ſenate, and in the following year was nominated miniſter of St. Martin's pariſh. Theſe inſtances of preferment he refuſed to accept, but upon the expreſs conditions that he ſhould be at perfect liberty to teach whatever was clearly warranted, according to his own opinions, by the ſacred Scriptures, and that he ſhould not be obliged to retain ſuch popiſh ceremonies as he conſidered to be uſeleſs. He now felt his mind at liberty, and openly preached againſt the leading tenets of the church of Rome, and was attended by very crowded auditories, who readily embraced the ſentiments of the reformers. One of the firſt alterations which he introduced, under the ſanction of public authority, was that of adopting the vulgar tongue at the baptiſm of infants. Afterwards the ſacrifice of the maſs was aboliſhed, and the ſacrament of the Lord's Supper was ordered to be adminiſtered in both kinds. Our reformer went ſtill further, and held up to contempt, as ſuperſtitious ceremonies, the uſe of holy water, conſecrated palms, tapers, &c. While the reformation was taking deep root at Baſil, the diſpute took place between Luther and Zuingle concerning the manner of Chriſt's preſence in the Euchariſt: in this controverſy Œcolampadius embarked on the ſide of Zuingle, and in 1525 publiſhed a Latin treatiſe in defence of his opinion, entitled "De vero intellectu verborum Domini, *hoc eſt corpus meum*," which was pronounced by the learned Eraſmus to be drawn up with ſo much ſkill and ingenuity, that even the elect were in danger of being ſeduced by it. In the year 1527, the reformers having been challenged by the Catholics to a public diſpute at Baden, Œcolampadius entered the liſts againſt Eckius, on the ſubjects of tranſubſtantiation, &c. the reformer declaring that he would not ſubmit to have the points at iſſue determined by any other rule of judgment than the word of God, and that none ſhould be acknowledged as judges who would not decide according to the canon of Scripture. After the diſcuſſions were ended, the Swiſs who were preſent formed themſelves into two parties, of which one awarded the victory to Eckius, and the other to Œcolampadius; and even the deputies from Baſil, where Œcolampadius was held in the higheſt eſtimation, were divided upon the ſubject. That the peace of the republic might not be diſturbed by the conteſts of their reſpective partizans for ſuperiority, the ſenate very judiciouſly and wiſely paſſed a law, confirming both to the Catholics and the reformed the equal enjoyment of religious liberty. In 1528 our reformer married, and having completed the reformation of the church at Baſil, he was called to Ulm, where, in conjunction with Martin Bucer, and others, he eſtabliſhed the church of that city upon the ſame plan of doctrine and diſcipline which had been adopted by the reformed Swiſs churches. In 1531, while he was diligently employed in the diſcharge of his office as miniſter of the church of Baſil, and zealouſly ſerving the intereſts of the reformed religion by his advice and writings, he was attacked by the plague, to which he fell a ſacrifice in the forty-ninth year of his age. To the excellence of his character, both Catholics and Proteſtants have borne ample teſtimony, and of his talents and learning his works afford ſufficient evidence; theſe, which are numerous, conſiſt of Annotations and Commentaries on the books of Geneſis, Job, and the Pſalms, and upon the prophecies, alſo on ſeveral books of the New Teſtament. He tranſlated into Latin various pieces of the fathers; wrote numerous controverſial treatiſes; and after his death an intereſting volume of "Letters" between him and Zuingle was publiſhed at Baſil in 1536. Moreri. Bayle. MS. Life of Luther.

ŒCONOMICS, ŒCONOMICA, that part of moral philoſophy

loſophy which teaches how to manage the affairs of a family, or houſhold.

ŒCONOMUS, οικονομος, a perſon appointed to direct and manage a vacant church revenue, or that of a hoſpital, or other community.

ŒCONOMUS was alſo anciently uſed for a protector, or advocate, who defended the rights and effects of churches, monaſteries, &c.

ŒCONOMUS was alſo an appellation given to a church-office, who took care of the buildings and repairs of the church, and received and diſtributed alms according to the directions of the biſhop.

In this ſenſe it is that the ſixth council appoints, that every church have its œconomus.

ŒCONOMY, οικονομια, the prudent conduct, or diſcrete and frugal management of a man's eſtate, or that of another.

ŒCONOMY, *Political*. See POLITICAL *Economy*.

ŒCONOMY, *Public*. See *Public* POLICE.

ŒCONOMY, *Animal*, the firſt branch of the theory of medicine; or that which explains the parts of the human body; their ſtructure and uſe; the nature and cauſes of life and health, and the effects or phenomena ariſing from them.

This is otherwiſe called *phyſiology*; and its objects juſt enumerated are called the *naturals*, or *res ſecundum naturam*.

ŒCONOMY, *Legal*, or *Jewiſh*, or *Diſpenſation*, is the manner wherein God thought good to guide and govern his people under the miniſtry of Moſes. See JUDAISM.

This included not only the political and ceremonial laws, but alſo the moral law, inaſmuch as it pronounced a curſe on all thoſe who did not fulfil it perfectly.

ŒCONOMY, *Evangelical*, or *Chriſtian*, or *Diſpenſation*, is uſed in oppoſition to the *legal*; and comprehends all that relates to the covenant of grace, which God has made with men by Jeſus Chriſt.

ŒCONOMY *of the Parts of Plants*. See PLANT.

ŒCUMENICAL, formed of the Greek οικουμενικος, of οικουμενη, the *habitable earth*, or the *whole earth*, ſignifies as much as *general* or *univerſal*.

In this ſenſe we ſay an œcumenical council or ſynod; meaning one at which the whole Chriſtian church aſſiſted, or to which they were invited.

Du-Cange obſerves, that many of the patriarchs of Conſtantinople aſſumed to themſelves the quality and denomination of œcumenical patriarchs; particularly John the Faſter in 590, and Cyril, his ſucceſſor. Gregory the Great of Rome was exceedingly enraged at it; pretending it was a title of pride, and the character of antichriſt; as ſuppoſing the title of œcumenical to imply univerſal biſhop, or biſhop of all the world: whereas, in effect, it implied no more than the quality of chief of the Eaſtern church; in like manner as the firſt doctor of the church of Conſtantinople was called *doctor œcumenicus*.

The title œcumenical biſhop was firſt offered to Leo I., but he refuſed it: nor did his ſucceſſors accept of it for a long time. The fifth council of Conſtantinople gave it to John, patriarch of that city; though ſome of the Romaniſts pretend, that the emperor Phocas gave it, by way of preference, to the biſhop of Rome. (See POPE.) But thoſe of Conſtantinople have preſerved it; and ſo late as the council of Baſil, that patriarch uſed the title. But œcumenical here is only to be underſtood as of the extent of each patriarchate.

ŒCUMENIUS, in *Biography*, an ancient Greek commentator upon the Scriptures, who is ſuppoſed to have flouriſhed in the 10th century, was biſhop of Trica in Theſſaly. He was author of Commentaries upon the Acts of the Apoſtles, and the fourteen epiſtles of St. Paul, and the ſeven Catholic epiſtles, which contain a conciſe and a perſpicuous illuſtration of thoſe parts of the New Teſtament. Beſides his own remarks and notes, they conſiſt of a compilation of the notes and obſervations of Chryſoſtom, Cyril of Alexandria, Gregory Nazianzen, Theodoret, and others. He is thought alſo to have written a commentary upon the four goſpels, compiled from the writings of the ancient Greek fathers, which is not now extant. The works of Œcumenius were firſt publiſhed in Greek at Verona in 1532, and in Greek and Latin at Paris in 1631, in two volumes folio. To the ſecond volume of the Paris edition is added the "Commentary" of Arethas upon the book of Revelation. Moreri. Lardner.

OEDA, in *Geography*, a town of Perſia, in Farſiſtan; 50 miles W. of Yezd. N. lat. 52° 25′. E. long. 11° 10′.

ŒDEMA, from οιδεω, *to ſwell*. The term œdema, as a modern ſurgical writer has obſerved, was employed by ſome of the ancient authors in a ſenſe ſynonimous with eminence, extuberance, or tumour; but, ſince the time of Galen, it has been more ſtrictly confined to thoſe tumefactions, which are derived from the effuſion of a fluid into the cells of the reticular membrane of a particular part. The fluid is of the watery or ſerous kind. When the cellular membrane is extenſively filled in this manner, the diſeaſe is not uſually called *œdema*, but *anaſarca*.

Mr. Pearſon has diſtinguiſhed ſix ſpecies of œdema; *viz.*

1. } Œdema { flaccidum.
2. } { durius.
3. Œdema ſymptomaticum, vel tumor œdematoſus.
4. Œdema deuteropathicum.
5. Œdema cum erythemate.
6. Œdema purulentum.

Of the Œdema Simplex Flaccidum.—This form of the œdema, ſays Mr. Pearſon, is characteriſed by a tumefaction of the integuments, commonly about the feet, ankles, and anterior ſurface of the tibia. There is no particular diſcolouration of the parts. It is unattended with pain; but there is uſually a ſenſe of weight and tightneſs, and the freedom of motion is more or leſs impaired. Firm preſſure upon the tumefied part produces a little cavity, which is not very quickly effaced, and the feet are generally ſomewhat colder than natural. The œdema uſually increaſes towards the evening, but, in conſequence of reſt and a horizontal poſition, it generally ſubſides during the night.

According to Mr. Pearſon, the remote cauſes are of the following deſcriptions.

1. Compreſſion of the larger veins, or of the trunks of the abſorbent veſſels.

Obeſity. Gravid uterus. Tumours within the abdomen. Sitting long on a hard ſeat. Riding long in a carriage, or on horſeback. Tight bandages. Unequal preſſure from ſplints, &c.

2. Whatever diminiſhes the powers which propel the returning blood.

A ſedentary life. Long expoſure to cold, without exerciſe, and in perſons of advanced age. Expoſure to cold and damp. Old age in ſubjects who have led inactive lives.

3. Injurious effects produced on the ſtomach.

Drinking exceſſively of diluting liquids, ſpirits, or fermented beverages. Intemperancce in eating.

4. Profuſe hemorrhages. Hypercatharſis.

5. Thoſe diſeaſes of the heart and lungs, which obſtruct the due tranſmiſſion of the blood through the pulmonary veſſels.

6. Local

6. Local injuries, as blows, ſprains; alſo inflammation, or eryſipelas of the lower extremities.

With regard to the prognoſis, the danger, or unimportance of this ſpecies of œdema, muſt principally depend upon the difficulty, or eaſe, with which the remote cauſe may be obviated.

In the treatment of the œdema ſimplex flaccidum, the indications are, to remove, if poſſible, the remote cauſe; to alter that ſtate of the ſyſtem, by which the diſeaſe is ſupported; and to promote the abſorption of the fluid diſtending the cellular membrane by means of purgatives and diuretic medicines. In the local treatment, the main objects are to facilitate the return of the blood by a horizontal poſture; to ſupport the parts, and promote abſorption, by the application of a flannel bandage; and to ſtrengthen the parts by friction, and the uſe of liniments. Bathing the parts in hot ſalt brine, or ſea-water, and the uſe of a laced ſtocking, will ſometimes both aſſiſt the cure, and prevent a relapſe.

Œdema Simplex Durius.—Mr. Pearſon obſerves, that this form of the diſeaſe appears in one, or both of the lower extremities; it is accompanied with pain, and ſome degree of lameneſs; but there is no diſcolouration of the ſkin, nor preternatural increaſe of temperature. The ſwelling is nearly uniform, and extends from a little below the knee to the ankle, ſeldom affecting the foot. The diſeaſed part is firmer than in the œdema ſimplex flaccidum, and yields very little to preſſure.

Mr. Pearſon conceives, that this diſeaſe is connected with a morbid ſtate of the deeply-ſeated abſorbents of the leg. It is ſaid to occur more frequently in women than men, and as often in young adults as in older perſons.

The remote cauſes are not always manifeſt. Amenorrhœa in plethoric habits; inactivity in corpulent perſons; and ſtanding a long while every day; are mentioned as circumſtances by which this ſpecies of œdema has been induced.

The treatment adviſed by the preceding gentleman, conſiſts in purging the patient every four or five days; giving ſmall doſes of calomel, with alkaline ſalt, on the intermediate days, enjoining reſt and a recumbent poſture, until the pain abates; and applying the vapour of ſpirit of wine and volatile alkali. When the hardneſs and extraordinary tenderneſs of the abſorbent veſſels are diminiſhed, he recommends the uſe of the linimentum ammoniæ, and the employment of a flannel bandage for a few weeks after the cure.

Œdema Symptomaticum.—This is ſtated to be not different from the œdema ſimplex flaccidum, and it is arranged under a ſeparate head, becauſe it occurs as a ſign of ſome other diſeaſe, without abſolutely conſtituting a part of it. Amongſt other caſes, the following are ſome, which this kind of œdema indicates the exiſtence of; ſimple fracture; fracture of the cranium; empyema; blood effuſed in natural cavities; deeply-ſeated abſceſſes; gangrene; diſeaſes of the perioſteum and bone; general debility, &c.

The cure of this complaint evidently depends upon the removal of the cauſe.

Œdema Deuteropathicum ſeu Puerperarum.—This form of œdema moſtly occurs about twelve or fifteen days after parturition; but it has ſometimes come on as early as the following day. In other inſtances, however, three or four weeks have elapſed before the attack. It uſually commences (ſays Mr. Pearſon) with pain about the calf of the leg, ſucceeded by tumefaction in the labium pudendi and groin, which gradually deſcends down the thigh, leg, and foot, ſo that, in the courſe of two or three days, the whole of the lower extremity acquires a very conſiderable increaſe of bulk. The limb is painful, preternaturally warm, and admits of no motion without great uneaſineſs being excited; but the colour of the ſkin is either unaltered, or whiter than natural. The integuments are firm, elaſtic, and do not yield to preſſure, as in the œdema ſimplex flaccidum. No water is uſually diſcharged on ſcarifying the part, nor is the ſwelling at all reduced by a horizontal poſition.

The diſeaſe never ſuppurates, nor does it leave any permanent induration, or lameneſs, although, in ſome caſes, ſeveral weeks elapſe before the patient recovers entirely the uſe of the limb.

The remote cauſes of this ſpecies of œdema do not appear to be underſtood with any degree of certainty.

The ſymptomatic inflammation may be relieved by ſuch medicines as promote a diaphoreſis; James's powder; ſaline draught with volatile alkali; liquor ammoniæ acetatis; ſmall doſes of the pulvis ipecacuanhæ compoſitus; camphor with opium, &c.

When the violence of the firſt ſymptoms has ſubſided, Mr. Pearſon adviſes the free exhibition of purgatives, eſpecially ſuch as are combined with calomel and alkaline ſalt, and they ſhould be repeated as frequently as the ſtrength of the ſyſtem will permit.

On the intermediate days, when the purgatives are not exhibited, Mr. Pearſon recommends bark, caſcarilla, myrrh, ſulphuric acid, and ſimilar tonics.

With reſpect to the local treatment, when the pain is very ſevere, the ſame gentleman thinks the application of leeches to the upper part of the thigh beneficial.

Anodyne fomentations; camphorated oil, with tincture of opium; and other liniments, are mentioned as uſeful; and a flannel bandage is to be applied as ſoon as the limb will bear it.

Other ſerviceable means are ſmall bliſtering plaſters; moderate exerciſe; and friction.

Œdema cum Erythemate.—This ſpecies of œdema is deſcribed by Mr. Pearſon as coming on ſuddenly; the patient complains of ſhivering, pain in the loins, nauſea, head-ache, &c. Theſe febrile ſymptoms ſeldom continue with violence more than twelve hours; but when they remit, a ſenſe of tingling is experienced in the foot and calf of the leg, extending to the groin. The whole of the lower extremity ſwells, becomes painful, and is almoſt univerſally red; the ſkin is very tender, and all motion gives great uneaſineſs. The abſorbent glands in the groin and upper part of the thigh alſo become conſiderably enlarged. The redneſs and ſwelling commonly begin to ſubſide in three or four days, the leg and foot remaining in a very œdematous ſtate.

This diſeaſe ſometimes attacks young women, whoſe menſes are not regular; but females, not at all affected with chloroſis, may have the complaint. Men are alſo occaſionally the ſubjects of the diſorder. The perſons moſt liable to be attacked, are thoſe who are corpulent; whoſe fibres are flaccid; whoſe occupations require much ſtanding; more eſpecially when thoſe perſons drink immoderately of ſpirituous liquors.

This diſeaſe is treated in the ſame manner as the œdema puerperarum.

Œdema Purulentum.—This form of œdema is leſs frequent than any of the former kinds, though as ſevere as the worſt of them. It uſually begins with ſhivering, increaſed heat, accelerated pulſe, debility, and other febrile ſymptoms. Soon after this attack, the patient complains of pain in his groin; the inguinal glands are enlarged and tender; and the thigh is hot, but not at all ſwelled or diſcoloured. In a few days the knee inflames, while the leg and foot become affected with the œdema ſimplex flaccidum. In about ten or fourteen days from the commencement of the diſeaſe,

two

two or three indurated parts, of ſmall dimenſions, may be diſcovered in the ham and inner part of the thigh, and now the whole limb is in general highly œdematous. When one of the indurations burſts, a large quantity of pus is diſcharged.

According to Mr. Pearſon, the œdema purulentum comes on without any evident cauſe. This gentleman has hitherto ſeen it only in young perſons, who were under the age of twenty years, and of a ſcrofulous habit.

During the firſt ſtage of this complaint, diaphoretics, combined with opium, are recommended. As ſoon as ſuppuration has occurred, Peruvian bark muſt be given with opium. This medicine muſt be continued after the abſceſs has burſt, and be aſſiſted with a generous diet, and country or ſea-air. The ſulphuric acid is alſo an eligible remedy.

When the abſceſs has burſt, Mr. Pearſon recommends applying dry lint and common digeſtive, care being taken to waſh the part, at each time of dreſſing it, with Bates's camphorated lotion. A roller will alſo do good.

ŒDEMOSARCA, from οιδημα and σαρξ, *fleſh*, an œdematous ſwelling, attended with a firm, fleſhy feel.

ŒDERA, in *Botany*, named by Linnæus in honour of George Chriſtian Oeder, once profeſſor of Botany at Copenhagen, to whom the *Flora Danica* was, at its beginning, entruſted. Having completed three volumes, containing 540 plates, he reſigned the botanical chair for another appointment under the Daniſh government, when the above work was conſigned to the care of Muller, and afterwards to Vahl. The other botanical publications of this gentleman are, *Elementa Botanicæ*, publiſhed at Copenhagen, in two parts, in 1764 and 1766; *Nomenclator Botanicus*, printed in 1769; and *Enumeratio Plantarum Floræ Danicæ*, printed in 1770. Oeder was born at Anſpach in 1728, and died at the age of 63 years. Linn. Mant. 159. Schreb. 590. Willd. Sp. Pl. v. 3. 2392. Mart. Mill. Dict. v. 3. Juſſ. 189. Lamarck Illuſtr. t. 720. Gærtn. t. 172.—Claſs and order, *Syngeneſia Polygamia Segregata*. Nat. Ord. *Compoſitæ Oppoſitifoliæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* many-flowered, ſquarroſe, of ſeveral, lanceolate leaves, longer than the flower; the lower ones larger; containing numerous *partial calyxes* of many, chaffy, lanceolate leaves, the length of the florets. *Cor. common* radiated, of many partial flowers which are alſo radiated though placed in the common diſk. Florets of each partial diſk perfect, funnel-ſhaped, five-cleft, erect: thoſe of the radius female, ligulate, lanceolate, the length of the common calyx. *Stam.* (in the perfect florets) Filaments five, very ſhort; anthers in a cylindrical tube. *Piſt.* (in the perfect florets) Germen oblong; ſtyle thread-ſhaped; ſtigmas two, thread-ſhaped, obtuſe; in the female florets the ſtigma is longer. *Peric.* none, except the unchanged calyx. *Seeds* oblong, crowned with many ſcales; pointed and ſhorter in the perfect florets. *Recept.* Common and partial, ſcaly; the ſcales of the latter linear, deciduous.

Eſſ. Ch. Partial calyx many-flowered. Florets tubular, perfect, with one or two female, ligulate. Receptacle chaffy. Down of ſeveral ſcales.

1. O. *prolifera*. Linn. Mant. 291. Suppl. 391. Thunb. Prodr. 169. (Bupthalmum capenſe; Linn. Sp. Pl. 1274. Amœn. Acad. v. 6. 104. Berg. Cap. 297.)—Leaves oppoſite, lanceolate, fringed, ſmooth on both ſides.—Found in ſandy ſituations at the Cape of Good Hope. *Stem* ſhrubby, compound, with aſcending *branches*, covered at the lower part with ſcars from fallen *leaves*. *Leaves* oppoſite ſeſſile, narrow, acute, channelled, chiefly abounding towards the end of the branches, green. *Flowers* terminal, ſolitary, yellow. *Seeds* compreſſed, ſlightly furrowed, ſmooth, light brown.

2. O. *aliena*. Linn. Suppl. 390. Jacq. Hort. Schoenb. v. 2. 14. t. 154. Frag. Bot. 5. t. 2. f. 9. (Arnica inuloides; Vahl. Symb. 91. Banks. MSS.)—Leaves linear, downy beneath. A native alſo of the Cape, where it flowers in July and Auguſt. *Stems* two or three feet high, very leafy, round, glaucous, branched. *Leaves* numerous but ſcattered, nearly ſeſſile, acute, much ſpreading, an inch and half long, reſembling thoſe of roſemary. *Flowers* almoſt ſeſſile, terminal, ſolitary, erect, of a very ſhowy yellow, as large as thoſe of the Marigold. *Seeds* white; their down ſtraw-coloured. The whole *ſhrub* is ſcentleſs, and has rather a bitter flavour.

Linnæus remarked that this plant might poſſibly belong to ſome other genus, for that it had the appearance of *Staehelina* or *Gnaphalium* with the flowers of *Calendula*. Vahl makes it an *Arnica*, under which name it appears in the herbarium of ſir Joſeph Banks.

3. O. *hirta*. Thunb. Prod. 169. Willd. n. 3.—Leaves ovate, entire, hairy.—This is alſo a Cape plant; but we know not that it is any where deſcribed or even noticed except by the authors above quoted.

OEDERAU, or Odern, in *Geography*, a town of Saxony, in the circle of Erzgebirg; 9 miles E.N.E. of Chemnitz. N. lat. 50° 48′. E. long. 13° 7′.

ŒDICNEMUS, in *Ornithology*, the name of a bird called alſo *charadrius* by Geſner and Aldrovand, and in Engliſh the *Stone* Curlew; which ſee.

OEDJONG Paca, in *Geography*, a town on the N. coaſt of the iſland of Java.

ŒDIPUS, in *Biography*, one of the ſemi-fabulous heroes of Greece, whoſe tragical adventures have been a favourite ſubject of the Grecian poets and dramatiſts; was the ſon of Laius, king of Thebes, in Bœotia, and Jocaſta, the daughter of Creon. The oracle of Apollo, according to the ancient tradition, having foretold that the ſon of Laius would be his father's murderer, he was given immediately after his birth to a ſhepherd, in order to be expoſed to wild beaſts. In this ſituation he was found by the herdſman of Polybius, king of Corinth, who brought him to his maſter: that prince educated him as his own ſon, and gave him the name of Œdipus, which referred to the ſwelling of his feet, occaſioned by their having been bored in order to hang him on the branch of a tree. When he came to adult age, he diſcovered that he was not the ſon of his reputed father, and went to the oracle of Delphos to enquire after his real parents. By the way he met with Laius at Phocis, and a quarrel ariſing between their attendants, in which the maſters took part, he had the misfortune to kill his unknown father. Another account relates that their encounter was owing to a ſedition in Phocis, in which Œdipus took a part againſt his father. He proceeded to Thebes, where his ſucceſs in expounding the enigma of the ſphinx, who is repreſented as the monſter that laid waſte the country, raiſed him to the throne and to the bed of the widow, his own mother Jocaſta. By her he had two ſons, Eteocles and Polynices. A train of circumſtances at length diſcloſed to him the parricide and inceſt of which he had been unknowingly guilty. Struck with horror at the unintentional criminality in which he had been involved, he tore out his eyes, as unworthy to behold the light, and taking ſanctuary in the grove of the furies in Attica, there ended his miſerable life. Jocaſta alſo put an end to her life, and to complete the tragedy, their ſons were diſtinguiſhed by the inveteracy of their mutual hatred. The death of Œdipus is placed by chronologiſts about the year 1228. B.C. Univer. Hiſt.

OEDMANNIA, in *Botany*, ſo called by Thunberg, in honour

honour of his countryman, the Rev. Samuel Oedmann, author of various treatiſes relating to natural hiſtory, publiſhed in Swediſh, in the Stockholm Tranſactions. Thunb. Prodr. præf. n. 46. Stockh. Tranſ. for 1800. 278. Willd. Sp. Pl. v. 3. 925. —Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-ſhaped, tapering at the baſe, ſmooth and even, two-lipped. Upper lip largeſt, deeply cloven; lower ſimple, awl-ſhaped, taper-pointed. *Cor.* papilionaceous, twice the length of the calyx. Standard large, ſtalked, elliptical; heart-ſhaped at the baſe; notched, with a ſmall point, at the tip; concave, ſmooth. Wings ſtalked, half-heart-ſhaped, oblong, obtuſe, undivided, half the breadth of the ſtandard, but of the ſame length. Keel of two ſtalked, half-heart-ſhaped, acute, boat-like petals, the length of the wings. *Stam.* Filaments ten, all united into a compreſſed tube, ſeparate and curved at the top, the length of the corolla; anthers oblong. *Piſt.* Germen ſuperior, linear-lanceolate; ſtyle thread-ſhaped, curved, rather longer than the ſtamens; ſtigma ſimple. *Peric.* Legume elliptical, ſmooth. *Seeds* . . . .

Eſſ. Ch. Calyx two-lipped; upper lip cloven; lower briſtle-ſhaped. Corolla papilionaceous; petals ſtalked. Legume elliptical.

1. O. *lancea.* Thunb. Prodr. 122. Stockh. Tranſ. for 1800. 281. t. 4.—Native of the Cape of Good Hope. The *ſtem* is about a foot high, rather herbaceous than ſhrubby, aſcending, ſimple, round, brown, leafy, quite ſmooth. *Leaves* alternate, ſeſſile, lanceolate, entire, ſmooth, an inch and half long, numerous, rather crowded, and nearly erect; their baſe tapering; their point acute. *Flowers* at the top of the ſtem, axillary, ſolitary, ſtalked, ſcarcely projecting beyond the leaves. Of their colour nothing is ſaid; their ſize is about that of a Lupine. This genus ranges next after *Borbonia*, with which it altogether accords in habit. The character of the calyx is very peculiar. Thunberg makes the legume elliptical, in his full deſcription of the genus, but lanceolate in his ſhort eſſential character. The figure of the germen renders the former moſt probable. We have ſeen no ſpecimen, but the plant is very likely to be confounded in our collections amongſt *Borboniæ* or *Lipariæ*.

OEGWA, or AGUA, in *Geography*, a town of Africa, on the Gold Coaſt, ſituated, between Elmina and Cape Coaſt, on the brow of an eminence, and defended by rocks, againſt which the waves beat with the utmoſt violence, and with a noiſe that is heard at a great diſtance; or, as others ſay, entirely commanded by the cannon of Elmina. Oegwa is ſaid by Barbot to contain about 500 houſes, disjoined by narrow crooked ſtreets; and from the ſea to have the appearance of an amphitheatre. Des Marchais reduces the number of houſes to 200, in the centre of which ſtands a large ſquare building, the repoſitory of their gold duſt and other commodities. The houſes are built of earth and clay, but convenient and well furniſhed. No part of the coaſt is better provided with articles of ſubſiſtence, which are brought from the adjacent cantons, and ſold in public markets. Every thing is bought and ſold with gold duſt, which is the ſtandard of all other commodities, and brought hither in great abundance from all quarters of Fetu, Abrambo, Aſſiento, and Mandingo. Next to gold, the chief commerce of the place conſiſts in the ſale of fiſh, of which great quantities are caught on the coaſt; in which operation the inhabitants are very ſkilful. The natives, though brave and warlike, are very induſtrious in time of peace, employing their whole time in catching fiſh, or cultivating the fruits of the earth. Every day in the week, except Wedneſday, which is ſacred to the fetiche, they employ in their ſeveral occupations. Their canoes weather ſtorms which would endanger the largeſt ſhipping; and the Negroes are dextrous in availing themſelves of thoſe ſeaſons, which oblige others to diſcontinue their labours, by throwing their fiſhing-lines with the ſame ſucceſs in tempeſtuous as in calm weather.

OEI, a river of China, which diſcharges itſelf into the grand canal, in the province of Chang-tong, at Li-tchin, or Lin-tcin.—Alſo, a city of China, of the ſecond rank, in the province of Chen-ſi. N. lat. 33° 48′. E. long. 105° 39′.

OELAMPANG, a town on the E. coaſt of the iſland of Java. S. lat. 8°.

OELAND, an iſland in the Baltic, belonging to Sweden, oppoſite to Calmar, about 70 miles long and 6 broad. In the north part are ſeveral fine foreſts and ſtone quarries; but in the ſouth part the ground is more level, and adapted both to tillage and paſture. This iſland affords plenty of butter, honey, wax, and nuts. The horſes, called "klappers," are ſmall, but ſtrong and mettleſome. The king's foreſt extends over the whole iſland; and here are numbers of various kinds of deer, with hares and wild boars. Both the N. and S. parts of the iſland abound in alum-mines. The Oeland ſand-ſtein, or free-ſtone, which is harder than that of Gothland, is ſupplied by this iſland; and alſo black marble or touch-ſtone. The ſea-weed is uſed here for manure. The inhabitants, amounting to the number of 7000 at leaſt, are employed in agriculture, working in the quarries, cutting of ſtones, burning of lime, fiſhing, and navigation. The ſailors belonging to the crown are generally quartered in this iſland. The four provoſtſhips into which Oeland is divided are in the dioceſe of Calmar. N. lat. 56° 45′. E. long. 16° 20′.—Alſo, an iſland of Denmark, in the Lymfiord gulf, about five miles long, and from 1 to 2½ broad; containing three or four villages. N. lat. 57° 4′. E. long. 9° 36′.

OELETS. See KALMUCKS.

OELLINGEN, or ELLINGEN, a town of Germany, in the circle of Franconia, which has a fine citadel belonging to the Teutonic knights, and is the uſual reſidence of the provincial commander; 20 miles S.E. of Anſpach. N. lat. 48° 59′. E. long. 10° 55′.

OELPE, a town of the duchy of Stiria; 4 miles S. of Wipperfurt.

OELS, a city of Sileſia, and capital of a principality of the ſame name. This town contains a reſidentiary palace of the prince, two Lutheran churches, a free-ſchool, and a Popiſh church. It has ſuffered much at different times by fire. The principality is bounded N. and E. by Poland, S. by the principalities of Oppeln, Brieg, and Breſlau, and W. by the principality of Wohlau. The ſoil is ſandy, and not very fertile; 14 miles E.N.E. of Breſlau. N. lat. 51° 10′. E. long. 17° 28′.

OELSEN, a town of Saxony, in the margraviate of Meiſſen; 6 miles N.E. of Launſtein.

OELSNITZ, a town of Saxony, in the Vogtland; 70 miles S.W. of Dreſden. N. lat. 50° 19′. E. long. 12° 15′.

ŒNANTHE, in *Botany*, a name adopted by old authors, which occurs in Theophraſtus and Dioſcorides, ſignifying the flower of the vine, derived from *οινη*, *the vine*, and *ανθος*, *a flower*. Tournefort applied it to the preſent genus, becauſe, he ſays, it bloſſoms at the ſame time with the vine, and becauſe its flowers reminded him of the ſmell and colour of the flowers of that plant.—Tourn. Inſt. 312. t. 166. Linn. Gen. 140. Schreb. 189. Willd. Sp. Pl. v. 1. 1440. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 317. Ait. Hort. Kew. ed. 2. v. 2. 147. Juſſ. Gen. 221. Lamarck Dict.

v. 4. 526. Illuſtr. t. 203. Gærtn. t. 22.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*.

Gen. Ch. *General umbel* of not many rays; *partial* denſe, of numerous, very ſhort, or no rays. *General involucrum* ſimple, ſhorter than the umbel; *partial* ſmall, both of many leaves. *Perianth* of five, awl-ſhaped, permanent teeth. *Cor. Univerſal* unequal, radiated. Florets of the diſk perfect, with five, inflexed, heart-ſhaped, nearly equal petals; of the radius, male, with five very large, unequal, inflexed, cloven petals. *Stam.* Filaments five, ſimple; anthers roundiſh. *Piſt.* Germen inferior, oblong, furrowed; ſtyles two, awl-ſhaped, permanent; ſtigmas obtuſe. *Peric.* none, except the nearly ovate fruit, diviſible into two parts, and crowned with the perianth and ſtyles. *Seeds* two, nearly ovate, convex on one ſide and ſtriated, flat on the other, toothed at the top.

Obſ. The perianth of *Œnanthe* is more conſpicuous than in any other umbelliferous genus.

Eſſ. Ch. Flowers irregular: thoſe of the radius ſeſſile and abortive. Fruit crowned with the calyx and ſtyles; its bark corky.

1. O. *fiſtuloſa*. Common Water Dropwort. Linn. Sp. Pl. 365. Engl. Bot. t. 363. Fl. Dan. t. 846.—Root ſending forth runners. Stem-leaves pinnated, cylindrical, tubular. General involucrum, for the moſt part, wanting. —Very common in wet ditches, pools, and marſhes, flowering in July and Auguſt.—*Root* perennial, tuberous, creeping. *Stems* erect, two or three feet high, branched, round, hollow like a pipe, inflated, furrowed, ſmooth, leafy, glaucous. *Radical-leaves* immerſed, bipinnate; leaflets flat, wedge-ſhaped, and lobed: *ſtem-leaves* alternate, pinnate; leaflets and ſtalks cylindrical and hollow. *General umbel* compoſed of from three to eight partial umbels, each furniſhed with numerous, fleſh-coloured *flowers*. *Calyx-teeth* ſharp and always ſpreading.

2. O. *crocata*. Hemlock Water Dropwort. Linn. Sp. Pl. 365. Engl. Bot. t. 2313. Jacq. Hort. Vind. v. 3. 32. t. 55.—All the leaflets wedge-ſhaped, cut, nearly equal.—"Happily (ſays Dr. Smith) this very noxious plant is of rare occurrence." It grows in moiſt places about the brinks of great rivers, as the Thames and others, flowering in July.—*Root* perennial, compoſed of numerous, ovate, fleſhy knobs. *Stems* erect, from two to five feet high, branched, ſomewhat forked, leafy, round, furrowed. *Leaves* dark-green, bipinnate; leaflets all nearly ſimilar, moſtly oppoſite, ſeſſile, veiny, ſmooth. *Umbels* terminal, large, convex, of many general and partial rays. *Flowers* white, often with purpliſh ſtyles and anthers, ſlightly radiant. *Calyx* incurved.

The whole herb abounds with a fetid, yellow juice, which is extremely virulent and poiſonous, eſpecially about the root. Ehret mentions that he was affected with a giddineſs only from drawing the plant. Sir Thomas Frankland informed Dr. Smith that, to his knowledge, brood mares have died in conſequence of eating the root.

3. O. *prolifera*. Proliferous Water Dropwort. Linn. Sp. Pl. 365. Jacq. Hort. Vind. v. 3. 35. t. 62.—The marginal, partial umbels male, on elongated, branched ſtalks.—Native of Italy and Sicily. It flowers in June and July.—*Root* perennial, tuberous. *Stem* herbaceous, nearly two feet in height, upright, ſlightly branched, green, purpliſh at the baſe, angular and ſtriated. *Leaves* triply pinnate; leaflets blunt, ſubovate or roundiſh. *General umbel* conſiſting of from five to eight convex rays of white or yellowiſh *flowers*, the central partial umbel very denſe, and much larger than the reſt. *Fruit* a compact, hard, hemiſpherical head.

4. O. *globuloſa*. Globular-headed Water Dropwort. Linn. Sp. Pl. 365. Gouan. Illuſtr. 18. t. 9.—Fruit globular.—Native of Portugal, and flowering in June and July.—*Root* perennial, branched. *Stem* a foot high or more, angulated and generally purpliſh at the baſe. *Radical-leaves* ternate or quinate, ſome of the leaflets lanceolate, ſome wedge-ſhaped, veiny, ſmooth. *Stem-leaves* pinnate; leaflets ſimple, narrow, long. *Umbel* of three or four unequal rays, each compoſed of twelve or fifteen *flowers*. *Fruit* globular, ſmooth, larger than that of coriander.—Gouan obſerves that this ſpecies has a great reſemblance to *O. pimpinelloides*, but is eaſily diſtinguiſhed by not having a lanceolate, triangular outline to its leaves, nor ſo branched a ſtem.

5. O. *peucedanifolia*. Sulphur-wort Water Dropwort. Pollich. Palat. v. 1. 289. t. 3. Engl. Bot. t. 348.—Leaflets all linear. General involucrum none. Knobs of the root ſeſſile, elliptical. Found in freſh inland waters, but by no means a common plant.—It was ſent from the neighbourhood of Bedford, and Bury, to Dr. Smith, who obſerves that no other Britiſh author except Dr. Sibthorp has noticed this ſpecies, probably from having confounded it with the following *O. pimpinelloides*. The flowers appear in June.—*Root* perennial, compoſed of elliptical, ſeſſile tubers, which are much crowded together. *Stem* thickiſh, rather firm, erect, angular, round, ſtriated, leafy, not much branched. *Radical-leaves* bipinnate; *ſtem-leaves* pinnate: all the leaflets linear, acute. *General umbel* conſiſting of five or ſeven rays, of denſe, yellow or often reddiſh, *flowers*.

6. O. *pimpinelloides*. Parſley Water Dropwort. Linn. Sp. Pl. 366. Engl. Bot. t. 347.—Leaflets of the radical leaves wedge-ſhaped, cloven; thoſe on the ſtem entire, linear, very long. General involucrum of ſeveral linear leaves.—Native of ſalt marſhes in various parts of Great Britain. It flowers in July.—*Root* perennial, compoſed of many ſpindle-ſhaped, ſlender, fleſhy tubers intermixed with fibres. *Stem* erect, or aſcending, nearly cylindrical, ſtriated, ſmooth leafy. *Radical-leaves* bipinnate; thoſe of the *ſtem* pinnate. *General umbel* terminal, compoſed of ten or twelve nearly equal rays. *Flowers* white, reddiſh at the back.—This ſpecies is completely a maritime one, and though no noxious properties are attributed to it, yet the very dangerous *O. crocata* cannot fail of making the whole genus ſuſpected of being poiſonous.

Thunberg in his Prodromus, 49, and 50, enumerates five additional ſpecies of *Œnanthe*, natives of the Cape of Good Hope.—They are *O. inebrians*, *tenuifolia*, *ferrulacea*, *interrupta*, and *exaltata*. Theſe are all adopted by Willdenow.

ŒNANTHE, in *Ornithology*, a name given to ſeveral ſpecies of *Motacilla*, as the *ſtapazina*, *œnanthe*, *rubetra*, *rubicola*, *trochilus*; which ſee. See alſo FRINGILLA *Petronia*.

ŒNARIA, a name given by the ancients to aſhes prepared from the leaves, tendrils, and young ſtalks of the vine. They were accounted highly diuretic.

ŒNAS, in *Ornithology*, the name uſed by authors for the ſtock-dove, or wood-pigeon, called alſo by ſome *vinago*, ſomewhat larger than the common pigeon, but of the ſame ſhape and general colour. Its neck is of a fine changeable hue, as differently oppoſed to the light; and its breaſt, ſhoulders, and wings, are of a fine purpliſh hue, or red wine colour, from whence it has its name *vinago*. Its legs are red, and feathered a little below the joint. See COLUMBA *Œnas* and *Migratoria*.

ŒNELÆUM, οινελαιον, formed of οινος, *wine*, and ελαιον, *oil*, in *Pharmacy*, a mixture of wine and oil; uſually of thick black wine, and oil of roſes.

In fractures with wounds, where the bone is not bare,

Scultetus orders that the compreſſes, to make them ſtick, be drenched with œnelæum, to ſooth the pain, and prevent an inflammation; and the bandage to be every day moiſtened with the ſame, till the inflammation be out of all danger.

ŒNISTERIA, in *Antiquity*, ſacrifices held by the youth of Athens, before the firſt time of cutting the hair, and ſhaving the beard.

The etymology of the word, which comes from οινος, *wine*, ſhews, that the matter here offered was wine.

Theſe ſacrifices were offered to Hercules; and the quantity of what was offered was regulated by law.

ŒNOGALA, a word uſed by Hippocrates, and other of the Greek authors, to expreſs a mixture of milk and wine for immediate drinking. Others have uſed it to expreſs wine alone heated, ſo as to be juſt as warm as new milk.

ŒNOMANTIA, οινομαντεια, in *Antiquity*, a ſpecies of divination by wine, which is done by making conjectures from the colour, motion, noiſe, and other accidents of the wine of libations.

ŒNOMAUS, in *Biography*, a Greek philoſopher, who flouriſhed in the ſecond century, uſually claſſed with the Cynics, was a native of Gadara, and flouriſhed in the reign of the emperor Adrian. He wrote a treatiſe to expoſe the frauds and impoſtures of oracles, which was very ably executed, and with a degree of freedom which would not have been permitted in a Chriſtian. He wrote another treatiſe, to cenſure the degeneracy of the latter Cynics; and Suidas aſcribes to him certain treatiſes on government, and the philoſophy of Homer, as well as the biographies of Crates, Diogenes, and other Cynic philoſophers. None of his pieces have reached our times; but fragments of his work againſt oracles are preſerved in the fifth and ſixth books of Euſebius's "Evangelical Preparation." Moreri. Brucker by Enfield.

ŒNOPTÆ, a kind of officers, or cenſors, at Athens, who attended at their feaſts, regulated the number of cups each was to drink, and took care that none drank too much or too little.

Thoſe who would not be kept within the bounds of temperance, were preſented by the œnoptæ to the areopagus. The œnoptæ were alſo called *eyes*, *oculi*.

ŒNOTHERA, in *Botany*, from οινος, *wine*, and θηρα, a *ſearching* or *catching*; a name, as we learn from Theophraſtus, beſtowed upon the plant on account of its root having caught the perfume of wine from being dried; but whether our *Œnothera* be the ſame as that of Theophraſtus we are at a loſs to determine. Linn. Gen. 187. Schreb. 250. Willd. Sp. Pl. v. 2. 306. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 341. Michaux. Boreal-Amer. v. 1. 224. Juſſ. 319. Lamarck Dict. v. 4. 550. Illuſtr. t. 279. (Onagra; Tournef. t. 156. Gærtn. t. 32.)—Claſs and order, *Octandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, deciduous; tube cylindrical, erect, long; limb cloven into four, oblong, acute, deflexed ſegments. *Cor.* Petals four, obcordate, flat, placed at the diviſions of the calyx, and as long as its ſegments. *Stam.* Filaments eight, awl-ſhaped, incurved, inſerted into the throat of the calyx, ſhorter than the corolla; anthers oblong, incumbent. *Piſt.* Germen inferior, cylindrical; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma four-cleft, thick, obtuſe, reflexed. *Peric.* Capſule cylindrical, ſquare, of four cells, and four valves; partitions contrary. *Seeds* numerous, angular, naked. *Recept.* columnar, unconnected, ſquare, its angles meeting the edges of the partition.

Eſſ. Ch. Calyx four-cleft. Petals four. Capſule of four cells and four valves, cylindrical, inferior. Seeds naked.

This is an ornamental genus of herbaceous plants, chiefly American. In the 14th edition of *Syſtema Vegetabilium* are enumerated ten ſpecies. Willdenow has fifteen, all of which may be found in the ſecond edition of the *Hortus Kewenſis*. We ſhall firſt give a few examples of theſe ſpecies.

O. *biennis*. Common Evening Primroſe. Linn. Sp. Pl. 492. Engl. Bot. t. 1534. Fl. Dan. t. 446.—Leaves ovato-lanceolate, flat. Stem rough, ſomewhat hairy. Stamens regular. Petals undivided.—This is the only Britiſh ſpecies of *Œnothera*, nor was it till very lately admitted as ſuch. It grows on the extenſive and dreary ſand-banks to the north of Liverpool, flowering from July to September. It was originally diſcovered in America, but is now naturalized almoſt throughout Europe, and is frequent in gardens. *Stem* two or three feet high, ſometimes branched, leafy, angular, rough with minute tubercles, hairy. *Leaves* alternate, ovate or lanceolate, toothed, downy; the loweſt ſtalked, longer and ſomewhat waved. *Flowers* ſeſſile in the boſoms of the upper leaves, ſo as to form a large ſpike. They are of a fine pale yellow colour, expand in the evening, and are delicately fragrant. The unfolding of the petals is ſo ſudden, that a ſort of exploſion has been heard, by ſome curious obſervers, in the ſeparation of the calyx-leaves.

O. *fruticoſa*. Shrubby Œnothera. Linn. Sp. Pl. 492. Curt. Mag. t. 332.—Leaves lanceolate, ſomewhat toothed, acute. Capſules ſtalked, oblong-club-ſhaped, angular.—Native of Virginia; flowering from June to Auguſt. *Root* perennial. *Stem* herbaceous, not really ſhrubby, three or four feet high, round, hairy, pale red. *Leaves* green on the upper ſide, glaucous beneath, tinged with red at their tips and edges. *Flowers* in cluſters, very large and ſhowy, bright yellow, expanding in the evening, but unlike moſt of the genus remaining open during the greater part of the following day. Curtis ſays "the flower-buds, the germen and the ſtalk are enlivened by a richneſs of colour, which contributes to render the ſpecies one of the moſt ornamental and deſirable of the tribe."

O. *pumila*. Dwarf Œnothera. Linn. Sp. Pl. 493. Curt. Mag. t. 355.—Leaves lanceolate, entire, obtuſe. Capſules on ſhort ſtalks, elliptically obovate, angular.—Native of North America. It flowers from May to September. *Root* perennial. *Stems* aſcending, ſcarcely a foot in height, ſmooth, reddiſh. *Leaves* ſeſſile, light green, tinged with red at their points, rather blunt. *Flowers* ſeſſile, ſpiked, ſmall, yellow, and like the laſt they remain expanded in the day as well as in the evening. This is by far ſmaller than any other Linnæan ſpecies of *Œnothera*.

O. *roſea*. Roſy-flowered Œnothera. Willd. n. 14. Curt. Mag. t. 347.—Leaves ovate, toothed; lower ones lyrate. Capſules club-ſhaped.—Native of Peru, and introduced into Europe in 1783. It flowers throughout the greater part of the ſummer. *Root* ſcarcely perennial. *Stem* about a foot in height, upright, ſmooth. *Leaves* nearly ſeſſile, pointed and tipped with red. *Flowers* ſolitary, on long ſtalks, of a bright roſe colour.

O. *purpurea*. Purple-flowered Œnothera. Willd. n. 15. Curt. Mag. t. 352.—Leaves glaucous, ſmooth, lanceolate, entire, attenuated at each end, obtuſe. Capſules ſeſſile, ovate, angular.—Native of North America, where it was diſcovered by A. Menzies, eſq. in 1794. A very ornamental ſpecies, and chiefly diſtinguiſhed by the ſoft and glaucous appearance of its foliage, the purple hue of its bloſſoms,

bloſſoms, and the dark colour of its ſtigma. *Root* annual. *Stem* about two feet high, rather waved, ſmooth. *Flowers* ſeſſile, ſpiked, very abundant, of a rich lilac or purple colour.

The other ſpecies of *Willdenow* and the *Hortus Kewenſis* are *O. grandiflora*, *parviflora*, *muricata*, *longiflora*, *molliſſima*, *undulata*; *nocturna*, *villoſa*, *ſinuata*, aud *tetraptera*.

Michaux divides the genus into two ſections; the firſt with *elongated fruit*; and the ſecond with *ſhort acutely quadrangular fruit*. In his ſecond ſection we find the following ſpecies, which are met with in no other author. *O. glauca*, *hybrida*, *linearis*, *chryſantha*, and *puſilla*.

The following South American ſpecies of this beautiful genus are deſcribed and figured in the fourth volume of *Cavanille's Icones*.

O. *tenella*. Cavan. Ic. t. 396. f. 2.—Stem herbaceous, erect. Leaves ovate-oblong. Four of the anthers nearly ſeſſile.—Found near Chili, flowering in November. *Stem* ſix or eight inches high, generally ſimple. *Leaves* alternate, the lower ones ſmaller, rather hairy. *Flowers* axillary, ſolitary, ſeſſile, violet-coloured.

O. *tenuifolia*. Cavan. Ic. t. 397.—Leaves linear, very narrow, elongated. Petals notched.—Native country, and time of flowering, as in the laſt. *Stems* round, a foot and half high. *Branches* numerous, ſlender, ſomewhat hairy, ſmooth when old. *Leaves* alternate, longiſh, ſeſſile. *Flowers* axillary, ſolitary, nearly ſeſſile, yellowiſh-red, with dark veins.

O. *dentata*. Cavan. Ic. t. 398.—Leaves linear, toothed. Capſules very ſlender, ſquare.—Found alſo in Chili and flowering in November. *Stem* a foot or more in height, round, with alternate branches. *Leaves* alternate, ſeſſile, thickly though minutely toothed. *Flowers* axillary, ſolitary, ſeſſile, yellow, with dark veins.

O. *acaulis*. Cavan. Ic. t. 399.—Leaves pinnatifid; the terminal lobe larger, toothed.—Found alſo near Chili, flowering in November and December. *Root* thick and fibrous, from whence ſpring the ſeſſile *flowers*, and all radical *leaves*, which are ſprinkled with white hairs. *Flowers* ſeveral, very large and ſhowy, of a white or fleſh colour beautifully variegated with veins.

O. *rubra*. Cavan. Ic. t. 400.—Stem herbaceous, erect, branched. Leaves ovato-acute, ſerrulated.—The country of this ſpecies is uncertain. It was cultivated in the Royal Garden of Madrid, where it flowered in July and Auguſt 1796. *Root* annual. *Stem* a foot high, round, branched. *Leaves* alternate, ſtalked. *Flowers* axillary, ſolitary, ſtalked, of a light red colour.

This laſt appears to us, notwithſtanding the author's remarks, to be but too near akin to the *roſea* above deſcribed.

ŒNOTHERA, in *Gardening*, compriſes plants of the herbaceous, biennial, perennial, and under-ſhrubby perennial kinds; of which the ſpecies cultivated are, the broad-leaved tree-primroſe (O. biennis); the long-flowered tree-primroſe (O. longiflora); the ſoft tree-primroſe (O. molliſſima); the ſhrubby tree-primroſe (O. fruticoſa); and the dwarf tree-primroſe (O. pumila).

Method of Culture.—Theſe plants are all capable of being raiſed from ſeeds, and ſome of them by parting the roots and cuttings.

The ſeed ſhould be ſown either in the autumn or early ſpring, in the firſt and third ſorts, upon a bed or border in the open ground, thinning and watering the plants properly, and keeping them free from weeds till the following autumn, when they may be removed, with balls of earth about their roots, to the places where they are to remain: or ſome may be ſet out, at the time of thinning, in nurſery-rows, ſix inches apart.

They alſo riſe without trouble, from the ſcattering of the ſeeds.

But in the ſecond ſort, the ſeed ſhould be put into the ground in the open borders, or other parts, about the latter end of March, where the plants are to remain. One plant is ſufficient in a place, which ſhould have a ſtick ſet to ſupport its branches, when they have advanced a little.

The fourth ſort may be readily increaſed by ſowing the ſeeds as above, and by parting the roots and cuttings of the young branches, planting them out in the open borders, or other places where they are to grow, in the autumn, for the firſt method, and the ſpring for the latter, giving water as there may be occaſion.

And in the fifth ſort, the ſeeds ſhould be ſown in pots of light earth in the autumn, plunging them in a hot-bed frame during the winter. When the plants have attained proper growth in the ſpring, they ſhould be removed into ſeparate pots, which ſhould be protected in the following winter under a garden-frame; and ſome may be planted out in the open ground, where they often ſucceed in mild winters.

The parted roots ſhould be planted out in the ſpring, either in pots or the open ground.

The plants raiſed from ſeed are in general the beſt, as flowering more ſtrongly.

By cutting down the ſtems of the plants in the firſt year of their flowering, before they perfect their ſeeds, the plants may ſometimes be rendered more durable.

The firſt two ſorts, as has been ſeen, are biennial, and the others perennial; the former ſhould, of courſe, be raiſed annually.

They are all proper for affording ornament and variety, either in the open ground, or among other potted plants. The ſecond and third ſorts are often conſidered as greenhouſe plants, but they ſucceed well in the open ground.

ŒPATA, in *Botany*, a name by which ſome authors have called the tree which produces the fruit called *anacardium Orientale*, or the Malacca bean.

OEPEN, in *Geography*. See EUPEN.

OERI. See AWERRI.

OERL, a town of France, in the department of the Roer; 10 miles N.W. of Venloo.

OERNETZ, a town of Sweden, in Dalecarlia, where Guſtavus Vaſa found refuge, and was prevented from being betrayed, by the wife of his hoſt; 5 miles S. of Fahlun.

OERNHIELM, CLAUDIUS, frequently called *Arrhenius*, in *Biography*, hiſtoriographer to the king of Sweden, was born at Linköping in the year 1627. Having been educated in his native place, he went for farther improvement to the academy at Upſal, where he applied himſelf very diligently to polite literature, making hiſtory the principal object of his purſuit. In 1657 he was invited to accompany the count Oxenſtierna in a tour to foreign countries; and on his return to Sweden, he became teacher in the academy of Upſal, and afterwards profeſſor of logic and metaphyſics. In 1668 he was choſen profeſſor of hiſtory; and in this ſituation he exerted his talents to throw light on the hiſtory of his own country, which till that period had been involved in great obſcurity. It was at this time that government eſtabliſhed an inſtitution, denominated the College of Antiquities, of which our author was appointed a member. This afforded him an opportunity to examine all the ancient records of the kingdom; and by theſe means he collected a moſt extenſive fund of materials for the favourite object of his purſuit. In 1687 he reſigned his profeſſorſhip, and was choſen librarian to the academy,

after having been ennobled by the name of Oernhielm. In 1689 he was made "Cenſor librorum regius," and died at Stockholm in 1695. The titles of his works are given in the General Biography: of theſe the principal are, "Hiſtoriæ Suecorum Gothorumque Eccleſiaſticæ Libri iv. priores;" "Vita Illuſt. Herois Ponti de la Gardie;" "Muſarum Upſalienſium Pietas in Carolum XI. Regem Sueciæ," 1673. Oernhielm had, previouſly to his deceaſe, been appointed by the government of his country to draw up a deſcription of all the towns, pariſhes, churches, &c. in Sweden, adapted to count Dahlberg's views of them; but this work was ſuſpended by his death.

OESCH, or Oex, in *Geography*, a town of Switzerland, in the canton of Berne; 19 miles S. of Friburg.

OESEL, a rocky iſland of the Baltic, or Eaſt ſea, called in Eſthnic *Kurraſaar*, *i. e.* Crane iſland, but by the inhabitants Sarema, *i. e.* the iſland. The former name is conjectured to have been formed from the Kures, who frequently made common cauſe with the Oeſelians; and the Lettiſh denominated this iſland Sahma femme, which might be changed into Sahna femme, *i. e.* Side-land. The length of the iſland, from Palmarort to the point lying ſouth-eaſt of the light-houſe of Soarverort, is about 11½ Swediſh miles, or nearly 118 verſts. In breadth it greatly varies: its largeſt being 9½ miles, or 99 verſts; and its ſmalleſt at the iſthmus, north-eaſt of the creek of Kylla, is about 2½ verſts. The temperature of the air is moderate and ſalubrious; the ſoil being in moſt parts ſand, loam, and clay, is therefore poor; but after good manuring with cow-dung or ſea-weed, and proper culture, it produces good corn, particularly wheat, rye, and barley; in favourable ſeaſons, likewiſe oats and peaſe. In dry ſummers, the parts that are quite ſandy ſeldom yield good barley, as it then runs altogether to ſtraw. On this iſland are many beautiful flowers; and the ſtone quarries are fine, and very productive. Many large blocks of limeſtone, which have been formed into ſtatues, and ſlabs for table-monuments, &c. as well as beautiful and rare ſtones, and marble, have been obtained from this iſland. The character of the Oeſel peaſantry much reſembles that of their brethren the Eſthonians; except that the former are more cleanly and orderly, and are generally not addicted to drinking; but if they indulge to exceſs, they prefer beer to brandy. In muſic and dancing, the Oeſelians manifeſt ſuperior taſte to that of the inhabitants of the adjacent continent; tolerable airs being produced by the boors from their favourite inſtrument, the bagpipe: they have likewiſe two ſorts of dances, one called the great or high dance, and the other the little dance. Their houſes are more commodious and better adapted to health than thoſe of the Eſthonians: they have windows, and ſome begin to have chimnies. In ſome few of the rooms they have deal-floors; and thoſe of the wealthier claſs no longer burn laths for light, but uſe tallow candles; and the opulent boors along the coaſt have iron lamps with ſea-dog oil. Theſe elegancies, however, are rare. The Eſthonians and Lettiſh are furniſhed annually with an almanac in their own language; but the boors of Oeſel make their own kalendar: for which purpoſe, as they cannot write, they have ſelected certain ſigns, which they mark in an artleſs manner on ſeven narrow flat ſticks tied together by a thong, or more properly on thirteen ſides. On each ſide is a month, conſiſting of 28 days. By this kalendar they learn at once every week-day, every immoveable feſtival, and every day that is memorable among them on account of any ſuperſtitious rites; for each has its peculiar ſign. They begin to reckon every ſucceſſive year one day later than the laſt; and in the uſe of the kalendar, they follow the practice of the Hebrews, and other Oriental nations, who begin their books at that part which we deem the end, and read from right to left. Tooke's Ruſſia, vol. i.

ŒSOPHAGEUS, in *Anatomy*, an epithet applied to the arteries, &c. of the œſophagus.

ŒSOPHAGOTOMY, in *Surgery*, from οισοφαγος, *the gullet*, and τεμνω, *to cut*, the operation of making an inciſion into the œſophagus, or gullet. The circumſtances under which ſuch a meaſure ſeems neceſſary, as well as the mode of operating, are detailed in the article ŒSOPHAGUS, *Removal of foreign Bodies from*.

ŒSOPHAGUS, in *Anatomy*, from φερω, οισω, *to carry*, and φαγω, *to eat*, the membranous and muſcular tube which conveys the food from the throat to the ſtomach. See DEGLUTITION.

ŒSOPHAGUS, *Removal of foreign Bodies from*, in *Surgery*. When an extraneous body lodges in the œſophagus, it ought either to be taken out, or forced down into the ſtomach.

1. The moſt ſimple method of executing the firſt of theſe operations, conſiſts in extracting the foreign body with the fingers, if it ſhould lie within their reach, or with forceps, the ſize and ſhape of which muſt vary according to circumſtances. If it ſhould be ſituated far down the paſſage, common forceps will not anſwer. They muſt then be made of a longer and ſtronger conſtruction, and curved like thoſe which are uſed for extracting polypi from the noſtrils. Such forceps, as well as other inſtruments, which will be preſently noticed, ſhould be carefully introduced. The patient being ſeated on a chair, with his head reſting upon the breaſt of an aſſiſtant, who is to keep it ſteady by applying his hands to the forehead, and hold it moderately back, the ſurgeon is to convey the index finger of his left hand over the baſe of the tongue, which muſt be depreſſed, and on this finger he is to conduct the forceps, obſerving to make them glide along the poſterior parietes of the œſophagus, in order that the larynx may not be at all touched, for when this happens, the latter part is irritated in a degree that always adds ſeriouſly to the patient's ſuffering.

When the foreign body has deſcended too far to be reached by the fingers or forceps, it may ſometimes be extracted with a long piece of ſtrong double wire, the extremity of which is ſhaped like a hook. This ſort of inſtrument would tear the internal membrane of the œſophagus, if it were not employed with the utmoſt caution. It has been recommended for the extraction of angular bodies. Theſe might be equally well removed, and without any riſk, by means of a flexible ſilver wire, doubled into a nooſe, and having its two ends twiſted one over the other. Some ſurgeons have made uſe of common catheters, into the eyes of which are introduced ſeveral looſe pieces of packthread. M. J. L. Petit ſuggeſted uſing, in this caſe, a whalebone probang, or long ſilver probe, at the end of which ſmall rings were placed, connected together like thoſe of a watch chain.

It was cuſtomary with the ancients to make the patient ſwallow a bit of ſponge dipped in oil, and attached to ſome thread, which paſſed through the middle of it. Fabricius Hildanus afterwards fixed the ſponge upon the end of a hollow ſilver, or copper-probe, perforated with apertures. Others conceived that the ſponge might be more conveniently introduced if it were fixed on ſomething flexible, like a long piece of whalebone. At length J. L. Petit rendered this inſtrument as ſafe as it could be made, by including the whalebone in a tube of flexible ſilver, which was conſtructed of ſpiral ſilver wire, while the ſponge was alſo faſtened by means of a wire of the ſame metal.

It may readily be conceived how bodies, whoſe form is angular, and ſubſtance ſolid, will follow the ſponge, in which their

their aſperities become engaged. Thoſe which are ſoft will not ſo eaſily do ſo, though ſome have occaſionally been drawn out, which, it was ſuppoſed, would never have been got hold of in this way. Dr. Cleghorn, a phyſician at Dublin, has related to the medical ſociety of London, an inſtance, in which he thus drew out of the œſophagus a quill, that a girl, deprived of her ſenſes, had let ſlip down this canal, in endeavouring to excite vomiting with it. One of Dr Cleghorn's friends, apprehenſive that the quill might, from its ſize, occaſion bad conſequences, if introduced into the ſtomach, was averſe to its being forced downward; and this phyſician conceived that if the ſponge could be got far enough down the œſophagus, the moiſture would make it expand, and that the feather of the quill might get entangled in it, and ſo admit of being extracted. For greater ſafety, he paſſed two ſtrings through the ſponge, in order that he might be able to pull it out in caſe it ſhould ſlip off the whalebone.

The inſtrument was introduced twice without ſucceſs; it was then turned round with a view of making the ſponge and ſtring take better hold of the feather. The plan did not ſucceed till the third attempt, when the extraneous ſubſtance was brought up high enough to admit of being taken hold of with the fingers, after it had remained in the throat two hours. Although the patient was bled the ſame evening, inflammation took place. Hence a ſecond bleeding became neceſſary; this gave relief, and the girl recovered. If the quill had paſſed into the ſtomach, it might have occaſioned acute pains in this organ, as the author of the "Zodiacus Medico-Gallicus" obſerved in a ſinging maſter, who was troubled for two years after ſwallowing ſuch an extraneous ſubſtance. The pain was violent for ſix months; no veſtiges of the quill were noticed in the ſtools. Another perſon at Dublin informed Dr. Cleghorn that a pen had been drawn out of the œſophagus in another inſtance by the preceding means. The pen was not extracted till the third attempt; the patient afterwards felt no inconvenience, and, the next day, called upon the gentleman who had relieved him, for the purpoſe of returning thanks.

2. When the foreign body, lodged in the œſophagus, cannot be removed by the means above explained, the only plan is either to promote its deſcent into the ſtomach, or elſe to force it down into this viſcus. The firſt of theſe indications is ſaid to have been ſometimes fulfilled by giving the patient a few gentle blows on the back with the palm of the hand, and alſo by making him laugh. When he can ſwallow liquids, we are likewiſe adviſed to direct him to drink a large quantity of water at a time. Sharp bodies of ſmall ſize have occaſionally been either carried downward, or rendered eaſy of deglutition, by means of pulpy food, ſuch as pap, bouillie, peaſe ſoup, French plums peeled, freſh figs, or dried ones turned inſide out. When theſe ſimple means do not anſwer, the foreign body muſt be puſhed down into the ſtomach. Anciently, a long metallic inſtrument was employed for this purpoſe; its end was the largeſt part of it, and rounded into the ſhape of an olive, or little ball. Its uſe was continued until the end of the 17th century, and Verduc recommended it at a ſtill later period. Paré, however, made uſe of a leek, the flexible ſtalk of which allowed it to adapt itſelf to the curvature of the parts through which it had to paſs. Fabricius ab Aquapendente preferred a large ſort of wax candle, which was oiled and ſoftened by being warmed. From an apprehenſion that the leek might break in the œſophagus, and thinking that the wax candle was likely to be either too hard, or too much ſoftened, M. J. L. Petit gave up theſe means, and propoſed the employment of ſponge fixed on a piece of whalebone, which was itſelf included in a ſilver cannula as already deſcribed. At the preſent day, the ſilver tube is not uſed, and the inſtrument, in its more ſimple form, is termed by ſurgeons a *probang*.

In the foregoing obſervations, it has been ſuppoſed that the ſuffocation produced by the foreign body in the œſophagus is not extremely urgent, and that the foreign body itſelf, the angular ſhape of which is known, admits of being diſplaced, and makes no external projection. Should it be of large ſize, and ſhould the preſſure, which it makes upon the trachea, interrupt reſpiration, as happened in the caſe recorded by M. Habicot in the Mém. de l'Acad. de Chirurgie, bronchotomy is indiſpenſably requiſite, after which the means calculated for the extraction of the foreign body, or for the promotion of its paſſage down into the ſtomach, muſt be practiſed. If the extraneous ſubſtance, though of ſmaller ſize, ſhould be firmly fixed, and project outwardly, there is a poſſibility of relieving the patient by making ſuch an opening into the œſophagus as will allow the foreign body to be extracted. Verduc, to whom we are indebted for the firſt ſuggeſtion of this operation, now termed *œſophagotomy*, aſſerts that its difficulties are amply counterbalanced by the danger in which the patient is of dying in the event of its not being performed. Guattani afterwards took up the ſubject, to which his attention was excited by an occurrence which he had an opportunity of witneſſing at Rome. A man, playing with a cheſnut, threw it up into the air, and caught it in his mouth. He ſoon complained of inability to ſwallow, and was conveyed to the hoſpital of the Santo Spirito. As he could ſpeak and breathe eaſily, had vomited ſince the accident, and was intoxicated when it happened, it was not ſuppoſed that the cheſnut had been ſwallowed. Very bad ſymptoms, however, came on, and he died on the nineteenth day. Guattani opened the left ſide of the neck, below the larynx and thyroid gland, which was conſiderably ſwelled. He ſoon came to the cavity of a large abſceſs, in which the entire cheſnut was ſituated. The œſophagus was much contracted both above and below this body, and the abſceſs which it had cauſed communicated with the trachea by a gangrenous aperture in the membranous parietes of the latter tube.

The obſervations of Euſtachius, Winſlow, Haller, and Morgagni, had apprized Guattani that the œſophagus, inſtead of deſcending in a ſtraight line along the back of the trachea, inclines a little to the left, and hence the latter ſurgeon propoſed opening the neck on that ſide in the operation of œſophagotomy. The patient being ſeated on a chair, with his head carried backward, and reſting on the breaſt of an aſſiſtant, the ſurgeon is to divide the integuments, the ſubcutaneous cellular ſubſtance, and that which lies betwixt the ſterno-hyoidei and thyro-hyoidei muſcles. Theſe muſcles and the trachea are then to be ſeparated from the œſophagus by drawing the ſides of the wound away from each other by means of blunt hooks. If any large veſſel ſhould bleed, it muſt either be ſecured with a ligature, or compreſſed with the finger of an aſſiſtant. Laſtly, an opening is to be made into the œſophagus over the foreign body, which is to be extracted with the fingers, or forceps. The wound requires only ſimple dreſſings, and from ſome experiments upon dogs, it is concluded that it will readily heal. Theſe experiments were attended with no difficulty, and that which Guattani performed in the preſence of M. Faget, upon the human dead ſubject, was done with equal facility.

The French academy of ſurgery, to which Guattani preſented his reflections, had annexed to an extract from his memoir two caſes of œſophagotomy, ſucceſsfully practiſed on two living men. One inſtance was communicated by

Gourſaud,

Gourſaud, a member of the academy. This fact, being detailed in a conciſe way, may be advantageouſly introduced in the preſent place. An individual ſwallowed a bone, an inch long, and ſix lines in breadth. Various endeavours were made to force it down into the ſtomach; but, as they were ineffectual, and the bone could be felt on the left ſide, Gourſaud's father made an inciſion over the foreign body, with a view of extracting it. The operation was followed by no remarkable ſymptoms. During a week, the patient took nothing by the mouth, being nouriſhed with glyſters. The hiſtorian of the academy adds, that a ſimilar operation was ſucceſsfully practiſed by a military ſurgeon, named Roland.

Extraneous ſubſtances of every kind, and eſpecially ſuch as have a ſharp figure, may elude all attempts made either to extract them, or force them down into the ſtomach. For a long while they may occaſion only ſuch inconveniences as are ſupportable, and, in the end, they may be voided by the mouth, or make their way through the parts between themſelves and the ſurface of the body, where they produce an abſceſs, from which they are diſcharged. In the firſt volume of the Memoirs of the French Academy of Surgery, M. Hevin has quoted from Hoeſteterus, a caſe, in which a young man, who, in his ſleep, had ſwallowed a piece of gold that he had put in his mouth, voided it from this part at the expiration of two years, after ſuffering a variety of complaints, and falling into a ſtate of coma, that threatened his life. The ſame author alſo cites ſome inſtances of foreign bodies, ſuch as pins, needles, and fiſh-bones, which, after lodging more or leſs time in the ſubſtance of the lungs, preſented themſelves externally, and were extracted by inciſions, which only reached through the integuments.

Amongſt the foreign bodies which ſlip into the œſophagus, there are many, which paſs through it into the ſtomach. If their ſubſtance ſhould be hard, their ſize conſiderable, and their figure ſharp, their preſence may give riſe to the utmoſt danger. Art can here afford little relief; but nature has reſources which ſeem extraordinary. The practitioner may, indeed, preſcribe oily and mucilaginous draughts, and thick ſoups, which will, in ſome meaſure, defend the alimentary canal from the rough ſurface of the extraneous ſubſtance. Perhaps, alſo, theſe means may alſo ſometimes have promoted the expulſion of the hurtful body. But nothing is clearer than that, in many of the caſes on record, they could have had no effect of the foregoing kind. A ſhoe-buckle, which a child ſwallowed in playing, has been known to be diſcharged with the ſtools. Likewiſe a ſmall tin cover, a pipe four inches in length, long pieces of the ſword blades, whole knife blades, a fork, a ſilver ſpoon, &c. after being ſwallowed, have, in different examples, been voided from the anus. But yet it frequently happens that bodies of theſe deſcriptions frequently deſtroy the patient, or cauſe abſceſſes in different parts of the abdomen, and are diſcharged with the matter. Laſtly, thoſe foreign bodies which paſs all through the inteſtinal canal, and preſent themſelves at the anus, often make their way through the coats of the rectum, and produce abſceſſes of the fundament. See Sabatier's Médecine Opératoire, tom. iii.

ŒSOPHAGUS, *Strictures of.* See STRICTURES.

ŒSOPHAGUS, *Wounds of.* See WOUNDS.

OESTRINGEN, in *Geography*, a town of the duchy of Baden; 14 miles E. of Spire.

ŒSTROMANIA, a name given by ſome authors to the uterine diſorders, which ſometimes affect young women, and is commonly called *furor uterinus*.

ŒSTRUM VENERIS. See VENERIS.

ŒSTRUS, the Gad-fly or Breeze, in *Entomology*, a genus of inſects of the order of Diptera: the generic character is as follows. The mouth has a ſimple aperture, and not exſerted; it has two feelers, each having two articulations; it is orbicular at the tip, and ſeated on each ſide in a depreſſion of the mouth; the antennæ have three articulations, the laſt of which is ſubglobular, and furniſhed with a briſtle on the fore-part, placed in two hollows on the front.

The face of this ſingular genus is broad and depreſſed; it is veſicular and glaucous, and has been thought to bear ſome reſemblance to the ape kind. The different ſpecies are extremely troubleſome and even deſtructive to horſes, ſheep, and other cattle, depoſiting their eggs in different parts of the body, and producing painful tumours and ſometimes death. The larvæ are without feet, ſhort, thick, ſoft, and annulate, and often furniſhed with ſmall hooks. There are twelve ſpecies, of ſeveral of which ſo full an account is given in our article BOTTS, that we feel it neceſſary, in this caſe, to do little more than enumerate the ſpecies, with a very brief deſcription of the ſpecific character.

Species.

* BOVIS. Wings immaculate, brown; abdomen with a black band in the middle and orange-yellow hair at the tip. It depoſits its eggs in the back of cattle under the ſkin, which, as they are changed into larvæ, produce a purulent tumour. The larva of this ſpecies is brown, and has eleven ſegments with tranſverſe, rough, interrupted lines.

* EQUI. Whitiſh, with a black band in the middle and two dots at the tip. There is a variety, of which the wings have a ſingle, oblong, black ſpot at the tip; the abdomen is covered with thick brown ferruginous hairs. This is the O. viſtuli of Fabricius.

* HÆMORRHOIDALIS. Wings immaculate, browniſh; abdomen black, the baſe white and fulvous at the tip. This inſect is about half the ſize of the laſt; the female has a black incurved appendage behind; the larva is leſs, but in other reſpects exactly like the laſt.

* VETERINUS. Wings immaculate; body ferruginous; ſides of the thorax and baſe of the abdomen with white hairs. This is the O. naſalis of Gmelin and the O. equi of Fabricius; it is leſs than the O. equi deſcribed above.

* OVIS. Wings pellucid, punctured at the baſe, abdomen variegated with black and white. This is leſs than the O. equi; the larva is white, ovate, pointed with two hooks, truncate behind, with a prominent margin, and two black reſpiratory ſcales. Above it is convex, with black lines and dots; beneath flat, with minute, rough, black dots in the middle of the ſegments.

Of all the foregoing ſpecies, which, as the aſteriſks ſhew, are to be met with in our own country, much intereſting matter will be found in the article BOTTS, already referred to. The reader is alſo referred to a valuable paper in the third volume of the Linnæan Tranſactions, in which the ſeveral ſpecies are all figured.

CUNICULI. Black; wings brown; thorax black as far as the middle, behind and baſe of the abdomen with yellowiſh hairs. It inhabits Georgia. It depoſits its eggs in the ſkins of hares and rabbits. It is twice as large as the O. bovis. The ſides of the abdominal ſegments are yellow; the body beneath is black. The larvæ are brown; every where rough, with very minute prickles.

BUCCATUS. Grey; face white, dotted with black. It inhabits Carolina, and is a large inſect.

TARANDI. The wings of this ſpecies are immaculate; thorax yellow, with a black band; the abdomen is fulvous, tipt with black. It inhabits Lapland. Depoſits its eggs

on the back of rein-deer, which produce larvæ, that are often fatal to them.

Trompe. Wings white; body black, with cinereous hairs; thorax with a deep black band. It inhabits Lapland, and on the rein-deer.

Antilopæ. Wings with a brown band and dots; body hairy, tawny-grey; abdomen with three rows of blackiſh ſpots. It inhabits Aſia, and depoſits its eggs on the back of the antelope.

Fasciculosus. Downy, yellow; tail with three tufts of blackiſh hairs This is a Siberian inſect.

Hominis. The body of this ſpecies is entirely brown. It inhabits South America. It depoſits its eggs under the ſkin, on the bellies of the natives. The larva, if it be diſturbed, penetrates deeper, and produces an ulcer, which frequently becomes fatal.

ŒSYPE, or Œsypos, a kind of fatty mucilage, of the conſiſtence of an unguent, of a greyiſh colour, and a ſickiſh diſagreeable ſmell, drawn from the greaſy wool growing on the throats and between the buttocks of ſheep.

The word is formed from the Greek οις, *ſheep*, and σηπω, *I putrefy*, or *corrupt*; the œſype being a filthy, and as it were, corrupted matter drawn from ſheep.

This wool they waſh, boil it in water, let the lotions or decoctions ſtand for ſome time, and from the top ſkim off a fatty ſubſtance, which being ſtrained through a linen cloth, and ſet to cool, makes the œſype much uſed externally to reſolve, ſoften, and appeaſe pain.

ŒTHODES Ulcus, a term uſed by the Greek writers for ſuch ulcers as had tumid and callous lips; and as ſuch ulcers are uſually very difficult to heal, the word became afterwards appropriated to all ſorts of ulcers difficult to cure.

OETSKAIA, in *Geography*, a town of Ruſſia, in the government of Irkutſk; 40 miles N. of Irkutſk.

OETTING, New, a town of Bavaria; eight miles N.W. of Burkhauſen. N. lat. 48° 12′. E. long. 12° 38′.

OETTINGEN, or Oetting, a county of Germany, ſituated N. of the Danube, bounded E. by the duchy of Nauburg, and W. by the provoſtſhip of Elwaugen; about 30 miles long and 18 broad. The Roman Catholic and Lutheran religion are equally profeſſed in the country.—Alſo, the capital of the fore-mentioned country, ſituated on the Wernitz, the ſeat of the regency and treaſury, and containing a ſociety of arts, a grammar-ſchool, and an orphan-houſe; 14 miles S. of Anſpach. N. lat. 48° 57′. E. long. 10° 37′.

OEVARA, a town of South America, in the province of Choco; 40 miles N. of Zitara.

ŒUVRE, Fr. Opera, Ital. This word, during the laſt century, and even earlier, was uſually prefixed to each work of a muſical compoſer; as Opera prima of Corelli, Opera quinta of Vivaldi, &c. But theſe titles ſeem now leſs in conſtant uſe than formerly. In proportion as muſic approaches perfection, it loſes theſe pompous names, by which authors imagined themſelves glorified. Rouſſeau.

OEYRAS, in *Geography*, a town of Portugal, in Eſtramadura, on the Tagus; eight miles W. of Liſbon.

Oeyras, *New*, a town of Africa, in the kingdom of Angola.

OFANTO, a river of Naples, which riſes near Conza, and runs into the Adriatic; 12 miles W. of Trani.

OFARA, a town of Japan, in the iſland of Niphon, and capital of a kingdom called Fida; 100 miles N.W. of Jedo.

OFENA, a town of Naples, in Abruzzo Ultra; 14 miles E. of Aquila.

OFESCA, a town of Servia, on the N. ſide of the Danube, oppoſite Belgrade.

OFF, a nautical term, applying to the movement of a ſhip when ſhe ſails from the ſhore towards the ſea. When a ſhip is beating to windward, ſo that by one board ſhe approaches towards the ſhore, and by the other more towards the ſea, ſhe is ſaid to ſtand *off* and *on* ſhore.

Off-*Bank* of a canal, is the bank I K, (*Plate* I. *Canals*, *fig.* 15.) which is on the contrary ſide of the canal from the towing-path *lc.*; and *off-ſlope* is the ſide L I, that is oppoſite to *l c.*

OFFA, in *Biography*, king of the Mercians, one of the Saxon princes of the heptarchy, whoſe power and talents have rendered them worthy of commemoration. He ſucceeded to the throne by the general conſent of the people, after a ſucceſsful inſurrection againſt Ethelbald, an uſurper, in 755. He had ſcarcely aſcended the throne, when he exhibited an ambitious ſpirit, which was not to be reſtrained within common boundaries: he made war upon Lothaire, king of Kent, and Kenwulph, king of Weſſex. The former he defeated in a bloody battle at Otford, a village near Seven-Oaks, and reduced his kingdom to a ſtate of dependence: over the latter he gained a victory at Benſington, in Oxfordſhire, and conquering that county, together with Glouceſter, annexed both to his dominions. Theſe ſucceſſes were ſtained by his treacherous murder of Ethelbert, king of the Eaſt-Angles, and his violent ſeizing of that kingdom. This young prince, who is ſaid to have poſſeſſed great merit, had paid his addreſſes to Elfrida, the daughter of Offa, and was invited with his retinue to Hereford, in order to ſolemnize the nuptial. Amidſt the joy and feſtivity of theſe entertainments, he was ſeized by Offa, and ſecretly beheaded: and though Elfrida, who abhorred her father's treachery, had time to give warning to the Eaſt-Anglian nobility, who eſcaped into their own country, Offa, having extinguiſhed the royal family, ſucceeded in his deſign of ſubduing that kingdom. At another time he joined Kenwulph in an invaſion of Wales, by which the Britons were driven to the mountains, and obliged to abandon all the low country. For the ſecurity of his conqueſts, Offa cauſed to be dug that dyke, which ſtill bears his name, extending from the mouth of the Wye to the Dee. Offa, by his various ſucceſſes, had now become the moſt potent prince in the iſland, and was even reſpected for his power and abilities by the celebrated Charlemagne, who entered into a league of friendſhip with him. At the deſire of that ſovereign the learned Alcuin was induced by Offa to viſit his court, and devote himſelf to his ſervice. The chief reaſon why he deſired the company of Alcuin was, that he might oppoſe his learning to the hereſy of Felix, biſhop of Urgil, in Catalonia, who maintained that Jeſus Chriſt, conſidered in his human nature, could more properly be denominated the adoptive, than the natural ſon of God. This hereſy was condemned in the council of Frankfort held in 794, conſiſting of 300 biſhops. "Such," ſays Hume, "were the queſtions which were agitated in that age, and which employed the attention not only of cloiſtered ſcholars, but of the wiſeſt and greateſt princes." Either real remorſe for his crimes, or a hypocritical affectation of piety, led Offa, in his latter years, to pay an almoſt unbounded reſpect to the clergy, and to practiſe all the ſuperſtitious devotion of the times. He gave a tenth of his goods to the church, and made liberal donations to the ſee of Hereford, which city was at that time his principal reſidence. He pretended to have been directed by a viſion to the reliques of the

the proto-martyr of England, St. Alban, near Verulam, and founded a magnificent monaſtery on the ſpot. At length he made a pilgrimage to Rome, where he laviſhed great ſums to procure the papal abſolution and benediction, and agreed to an annual payment to the pope for pious and charitable purpoſes, which he raiſed by a heavy tax on his ſubjects, afterwards converted into the impoſition termed Peter-pence. Offa died in 794, after a reign of thirty-nine years of uninterrupted external proſperity. Malmeſbury, one of the beſt of the old Engliſh hiſtorians, declares himſelf at a loſs to determine whether the merits or the crimes of this prince preponderated. Hume and Henry.

Offa *Alba*, a name which Van Helmont gives to the white coagulum, ariſing from a mixture of rectified ſpirit of wine with ſpirit of urine, or ſpirit of ſal ammoniac.

Note, The ſpirit of urine muſt be diſtilled from well fermented wine, and the other muſt be well dephlegmated; elſe no offa will ariſe.

Some call it the offa alba of Paracelſus, others of Van Helmont; whence it is ſometimes called *offa Helmontiana;* but Van Helmont was not the inventor of it, but Raim. Lully, ſays Boerhaave.

The manner of making the offa alba is deſcribed by this laſt author, who obſerves it to be difficult, as it requires both liquors to be perfect, and ſome nice circumſtances to be obſerved.

Van Helmont endeavours to account for the formation of the ſtone in the bladder, from this experiment; but as Boerhaave obſerves, the offa alba has nothing in common with the ſtone.

Boerhaave recommends this mixture as a good deobſtruent, taken in Canary, faſting.

Offa's *Dyke*, in *Geography*. See *Offa's* Dyke.

OFFAK Harbour, a port on the N. coaſt of the iſland of Waygoo, on the Line. E. long. 131° 6′.

OFFELING, a town of Auſtria; 16 miles S.W. of Freyſtadt.

OFFEN. See Buda.

Offen *See*, a lake of Auſtria; 16 miles E. of St. Wolfgang.

OFFENBACH, a town of Germany, in the county of Iſenburg, on the Maine, containing two Proteſtant churches, a ſynagogue, and quay, and ſeveral manufactures; three miles E. of Frankfort on the Maine.

OFFENBURG, a town of Germany, ſituated on the Kinzeg, in the Ortenau, originally imperial. In the year 1802, it was given to the duke of Baden. The inhabitants are Roman Catholics; 24 miles S.S.W. of Raſtatt. N. lat. 48° 27′. E. long. 7° 58′.

OFFENCE, Delictum, in *Law*, an act committed againſt the law, or omitted, where the law requires it.

Offences are diſtinguiſhed into two kinds, *viz.* ſuch as are capital, and ſuch as are not. Capital offences are thoſe for which the offender is to loſe his life. Thoſe not capital, where the offender may forfeit his lands and goods; be fined, or ſuffer corporal puniſhment, or both, but not loſe his life. (Hale, P. C. 2. 126. 134.) Under capital offences are comprehended high treaſon, petit treaſon, and felony; and offences not capital include the remaining part of the pleas of the crown, and come under the title of miſdemeanours.

Some offences are puniſhable by the common law, but moſt of them by ſtatutes.

Judge Blackſtone diſtributes the ſeveral offences, which are directly or by conſequence injurious to civil ſociety, and therefore puniſhable by the laws of England, under the following general heads: firſt, thoſe which are more immediately injurious to God and his holy religion; ſecondly, ſuch as violate and tranſgreſs the law of nations; thirdly, ſuch as more eſpecially affect the ſovereign executive power of the ſtate, or the king and his government; fourthly, ſuch as more directly infringe the rights of the public or commonwealth; and, laſtly, ſuch as derogate from thoſe rights and duties, which are owing to particular individuals, and in the preſervation and vindication of which the community is deeply intereſted. To the firſt claſs belong *apoſtaſy*, *hereſy*, thoſe which affect the eſtabliſhed church, by reviling its ordinances or nonconformity to its worſhip, *blaſphemy*, profane and common *ſwearing* and *curſing*, the offence of *witchcraft*, *conjuration*, *inchantment* or *ſorcery*, that of *religious impoſtors*, *ſimony*, profanation of the Lord's day, vulgarly (but improperly) called *Sabbath-breaking*, *drunkenneſs*, and open, notorious *lewdneſs*. The ſecond claſs of offences comprehends violation of *ſafe-conducts* or *paſſports*, thoſe which affect the rights of *embaſſadors*, and the crime of *piracy*. The offences belonging to the third general diviſion are *treaſon*, *felonies* injurious to the king's *prerogative*, *premunire*, and other *miſpriſions* and *contempts*. The fourth claſs of offences may be divided into five ſpecies, *viz.* offences againſt public *juſtice*, againſt the public *peace*, againſt public *trade*, againſt the public *health*, and againſt the public *police* or *economy*. The laſt claſs includes crimes and miſdemeſnors againſt private ſubjects, which are principally of three kinds, againſt their *perſons*, their *habitations*, and their *property*. For an account of each of the offences above enumerated, and thoſe that belong to each claſs, we refer to the appropriate articles in the Cyclopædia.

OFFENHAUSEN, in *Geography*, a town of Germany, in the territory of Nuremberg; five miles N.N.W. of Altorff.

OFFERING. See Oblation, and Heave-*offering*.

Offering, *Burnt*. See Holocaust.

OFFERTORY, Offertorium, an anthem ſung, or a voluntary played on the organ, at the time the people are making an offering.

Anciently, the offertory conſiſted of a pſalm ſung with its anthem; though it is ſomewhat dubious whether the pſalm was ſung entire; St. George mentioning, that when it was time, the pope, looking at the choir who ſung it, gave the ſign when they ſhould end.

Offertory was alſo a name anciently given to the linen whereon the offerings were laid. Dr. Harris ſays, it was properly a piece of ſilk, or fine linen, wherein the occaſional oblations or offerings of each church were wrapped up.

OFFICE, Officium, in a moral ſenſe, denotes a duty; or that which virtue and right reaſon direct a man to do.

Virtue, according to Chauvin, is the purpoſe of doing well: the thing which immediately follows, or ariſes from this purpoſe, is obedience; which ſame is alſo denominated *officium:* ſo that an office is the object of an obedience to *virtue;* which ſee.

Cicero, in his diſcourſe of "offices," cenſures Panætius, who had written before him on the ſame, for omitting to define the thing or ſubject on which he wrote; yet he does himſelf fall under the ſame cenſure. He inſiſts much on the diviſion of offices, but forgets the definition. In other of his pieces we find him defining office to be an action, which reaſon requires to be done: "Quod autem ratione actum ſit, id officium appellamus."

The Greeks, he obſerves, made two ſpecies of office: *perfect*, called by them κατορθωμα; and *common*, or *indifferent*, called καθηκοι: which they define ſo, as that, what is abſolutely right, makes a *perfect* office; and what we can

only give a probable reaſon for, a *common* or *intermediate* office.

Office, in a civil ſenſe, denotes the mutual aid and aſſiſtance which men owe to one another.

Benevolence inſpires a man with an endeavour to do good offices to all mankind.

Office is alſo a particular charge, or truſt, whereby a man is authorized to do ſomething.

Loyſeau defines office a dignity attended with a public function. The word is primarily uſed in ſpeaking of the offices of judicature and policy: as, the office of a ſecretary of ſtate, that of a juſtice of peace, of a ſheriff, &c.

Offices are either venal, or not venal. *Venal* offices are thoſe bought with money; and they are ſubdivided into two kinds; viz. *dominial* and *caſual*. *Dominial*, or *offices in fee*, are thoſe abſolutely torn off, and ſeparated from the king's prerogative, ſo as not to become vacant by death, but paſſing in the nature of a fee or inheritance.

Of theſe we have but few inſtances among us, which go beyond a firſt reverſion. Among the French they are more frequent.

Caſual offices are thoſe given for life, by patent, commiſſion, &c., and which become vacant by the officer's death, to the king's benefit; unleſs the officer have before reſigned, or diſpoſed of it.

Office, *Alienation*, *Alternate*, *Crown*, *Jewel*, *Poſt*. See the reſpective articles.

Office, *Victualling*. See Victualling.

Office is alſo uſed for a place, apartment, or board appointed for the officers to attend in, for the diſcharge of their reſpective duties or employments.

Such are the ſecretary's office, firſt fruits office, the ſix clerks office, the paper office, ſignet office, the prothonotary's office, pipe office, king's ſilver office, exciſe office, office of ordnance, &c. See Secretary, First-*fruits*, Six Clerks, Paper, Pipe, Signet, Excise, Ordnance, &c.

Of ſuch offices, ſome are diſtinguiſhed by the name of *board*, and other of *chambers*, as the board of green cloth, &c.

Where the inquiſition obtained, the tribunal of it was called the *holy* office.

Office, in the *Canon Law*, is uſed for a benefice, which has no juriſdiction annexed to it. See Benefice.

Office is alſo uſed, in *Common Law*, for an inquiſition or inqueſt of office, which is an inquiry made by the king's officer, his ſheriff, coroner, or eſcheator, *virtute officii*, or by writ ſent to them for that purpoſe, or by commiſſioners ſpecially appointed, concerning any matter that intitles the king to the poſſeſſion of lands or tenements, goods or chattels. (Finch. L. 323, 4, 5.) This is done by a jury of a determinate number; being either twelve, or leſs, or more. Theſe inqueſts of office were more frequently in practice than at preſent, during the continuance of the military tenures amongſt us: when, upon the death of every one of the king's tenants, an inqueſt of office was held, called an "Inquiſitio poſt mortem," to inquire of what lands he died ſeiſed, who was his heir, and of what age, in order to entitle the king to his marriage, wardſhip, relief, primer-ſeiſin, or other advantages, as the circumſtances of the caſe might turn out. To ſuperintend and regulate theſe inquiries the court of wards and liveries was inſtituted by 32 Hen. VIII. c. 46; which was aboliſhed at the reſtoration of king Charles II., together with the oppreſſive tenures upon which it was founded. With regard to other matters, the inqueſts of office ſtill remain in force, and are taken upon proper occaſions; being extended not only to lands, but alſo to goods and chattels perſonal, as in the caſe of wreck, treaſure-trove, and the like; and eſpecially as to forfeitures for offences. For every jury which tries a man for treaſon or felony, every coroner's inqueſt that ſits upon a felo de ſe, or one killed by chance-medley, is, not only with regard to chattels, but alſo as to real intereſts, in all reſpects an inqueſt of office; and if they find the treaſon or felony, or even the flight of the party accuſed, (though innocent,) the king is thereupon, by virtue of this "office found," entitled to have his forfeitures; and alſo, in the caſe of chance-medley, he or his grantees are entitled to ſuch things by way of deodand, as have moved to the death of the party. Theſe inqueſts of office were deviſed by law, as an authentic means to give the king his right by ſolemn matter of record; without which he in general can neither take nor part from any thing. For it is a part of the liberties of England, and greatly for the ſafety of the ſubject, that the king may not enter or ſeize any man's poſſeſſions upon bare ſurmiſes, without the intervention of a jury. (Finch. L. 82. Gilb. Hiſt. Exch. 132. Hob. 347.) It is, however, particularly enacted by 33 Hen. VIII. c. 20. that, in caſe of attainder for high treaſon, the king ſhall have the forfeiture inſtantly, without any inquiſition of office. And as the king hath (in general) no title at all to any property of this ſort before office found, therefore it was enacted by 18 Hen. VI. c. 6. that all letters patent or grants of lands and tenements before office found, or returned into the exchequer, ſhall be void. And by the bill of rights 1 W. & M. ſt. 2. c. 2. it is declared, that all grants and premiſes of fines and forfeitures of particular perſons before conviction (which is here the inqueſt of office) are illegal and void; which indeed was the law of the land in the reign of Edward III. (2 Inſt. 48.) With regard to real property, if an office be found for the king, it puts him in immediate poſſeſſion, without the trouble of a formal entry, provided a ſubject in the like caſe would have had a right to enter; and the king ſhall receive all the meſne or intermediate profits from the time that his title accrued. (Finch. L. 325, 6.) As on the other hand, by the "articuli ſuper cartas," 28 Edw. I. ſt. 3. c. 19, if the king's eſcheator or ſheriff ſeize lands into the king's hand without cauſe, upon taking them out of the king's hand again, the party ſhall have the meſne profits reſtored to him. In order to avoid the poſſeſſion of the crown, acquired by the finding of ſuch office, the ſubject may not only have his "petition of right," which diſcloſes new facts not found by the office, and "monſtrans de droit," which relies on the facts as found; but alſo he may (for the moſt part) "traverſe" or deny the matter of fact itſelf, and put it in a courſe of trial by the common law proceſs of the court of chancery. Yet ſtill, in ſome ſpecial caſes, he hath no remedy left but a mere petition of right. (Finch. L. 324.) Theſe "traverſes," as well as the "monſtrans de droit," were greatly enlarged and regulated for the benefit of the ſubject, by the ſtatutes already mentioned and others. (34 Edw. III. c. 13. 36 Edw. III. c. 13. 2 & 3 Edw. VI. c. 8.) And in the traverſes thus given by ſtatute, which came in the place of the old petition of right, the party traverſing is conſidered as the plaintiff; and muſt therefore make out his own title, as well as impeach that of the crown, and then ſhall have judgment "quod manus domini regis amoveantur," &c. Blackſt. Com. b. iii.

From what we have delivered it appears that to traverſe an office, is to traverſe an inquiſition taken of office before an eſcheator. To return an office, is to return that which is found by virtue of the office.

There are two ſorts of offices iſſuing out of the exchequer

by commiſſion; *viz.* an office to entitle the king in the thing enquired into; and an office of inſtruction.

Office is alſo uſed for divine ſervice celebrated in public. St. Jerom is the perſon, who, at the requeſt of pope Damaſus, is ſaid to have firſt diſtributed the Pſalms, Epiſtles, and Goſpels, in the order in which they are now found in the Romiſh office. The popes Gregory and Gelaſius added the prayers, reſponſes, and verſes; and St. Ambroſe the graduals, hallelujahs, &c.

Office is more particularly uſed, in the Romiſh church, for the manner of performing the ſervice; which varies every day.

Thus they ſay the office of Sunday; the office of ſuch a ſaint, &c. The office is either *ſingle*, *half-double*, or *double*.

Office, again, is applied to a particular prayer preferred in honour of a ſaint.

When any perſon is canonized, a particular office is at the ſame time aſſigned him out of the common office of the confeſſors, the Virgin, or the like. See Saint and Canonization.

We ſay, the office of the Virgin; of the Holy Spirit; of the paſſion; the holy ſacrament, &c. The office of the dead is rehearſed every day, excepting on feaſt-days, among the Carthuſians. The office of the Holy Virgin is alſo added to the office of the day, in the order of Bernardines.

Offices, with regard to *Architecture*, denote all the apartments that ſerve for the neceſſary occaſions of a great houſe, or palace, or thoſe where the ſervants are employed: as kitchens, pantries, brewhouſes, confectionaries, fruiteries, granaries, &c. as alſo waſh-houſes, wood-houſes, ſtables, &c.

The offices are commonly in the baſſecour; ſometimes they are ſunk under ground, and well vaulted.

Office, in *Rural Economy*, the general name of any ſort of farm, building, or place where buſineſs is tranſacted relative to a farm; or for the purpoſe of containing the animals, produce, or other things belonging to the farm. The great points to be aimed at in buildings of this kind are thoſe of convenience and economy in labour. See Farm-Buildings.

Office *of Eſtate*, the name of the place where the principal buſineſs of it is tranſacted. Mr. Marſhall, in his work on landed property, ſays it ſhould be ſituated under the roof of the principal reſidence of the proprietor, round which his eſtate moſtly lies. Where much land lies detached, a ſecondary office ſhould be provided. And it may be laid down as a rule, in the management of landed property, that every diſtinct part of an extenſive eſtate ought to have a place upon it, however humble, in which the poſſeſſor may paſs a few days, to diffuſe over it a ſpirit of good order and emulation. He has known the moſt neglected, and almoſt ſavage ſpot, reclaimed, and put in a train of improvement, by this eaſy method. And hence the utility of conſolidating landed property, and throwing it into compact bodies; ſo that due attention may be conveniently paid to every part.

It is ſuggeſted that a *principal* office ſhould have a commodious buſineſs room; a ſmall anti-room, lobby, or waiting room; and a ſafe, keep, or ſtrong room, for the more valuable documents.

Concerning the kinds of furniture, with which an office of this ſort ſhould be ſupplied, they are,

1. General maps of the diſtinct parts of the eſtate, or of the different officiaries, or diſtricts, into which the more connected parts may be divided,—coloured ſo as to ſhew, diſtinctly, each farm, or the lands that are eventually intended to be laid into ſeparate farms,—with the woodlands, waters, &c. &c. in hand. And alſo ſeparate pocket-maps of the ſeveral farms, or intended farms; exhibiting, at one view, the outlines, the names, and the contents, of the different fields or pieces of land of which they are ſeverally compoſed,—and coloured agreeably to their occupancy; ſo that the ſeveral fields of the exiſting farms, (or intermixed parts of farms, intended to be united,) though ſcattered, may be readily perceived. If ſeparate columns of contents be endorſed on the backs of the maps, one of them of the intended farm, the others of the exiſting farms, or parts of farms, with their ſeveral totals ſubjoined, all the doubts and perplexity which are wont to ariſe on large eſtates, from the intermixture of farm lands, will, he thinks, be avoided. See Map.

2. The rentals and books of accounts.

3. Books of valuation; or 'field books;' namely, regiſters of the number, name, admeaſurement, and eſtimated value of each field, and every parcel of land, as well as of each cottage, or other building, not being part of a farmſtead, on the ſeveral diſtinct parts or diſtricts of the eſtate.—The valuations being inſerted in columns; as they ariſe whether by general ſurveys, or incidentally; headed with the names of their reſpected valuers; ſo that whenever a farm is to be re-let, theſe columns may be conſulted, and its real value be fixed, in a re-ſurvey, with the greater exactneſs.

4. A general regiſter of timber trees, growing on the ſeveral diviſions of the eſtate; ſpecifying the number in each wood, grove, hedge-row, and area;—with the ſpecies, number, and meaſurement, of each tree. Alſo ſeparate pocket books, containing thoſe of each diviſion; for the occaſional uſe of the manager and the wood-reeve.

5. A receptacle of ordinary papers,—ſuch as contracts, agreements, accounts, letters of buſineſs, &c.—intelligibly endorſed, dated or numbered, and arranged ſo as to be eaſily referred to. With a book of abſtracts, or heads, of papers of great importance, to be referred to on ordinary occaſions, and likewiſe to ſerve as an index to the originals, which require a more ſecure repoſitory than a common buſineſs room.

6. A ſafe repoſitory of documents; as title deeds, legal deciſions, awards of arbitration, counterparts of leaſes, paſſed accounts, &c. The moſt ſecure keep of important papers, is a ſmall room, ſtrongly arched over; having an iron door, opening into the office with a window ſhutter, alſo of iron: thus guarding the contents, on every ſide, from fire; the repoſitory of writings being inſulated; in the centre of the room. And a ſtanding regulation, reſpecting papers, whether they may be lodged in the office, or the ſtrong room, ought to be,—that no perſon be ſuffered to carry away a valuable paper, on any occaſion, without leaving in its place a receipt or memorandum, ſignifying by whom it was taken, and for what purpoſe; in order that it may be the more eaſily traced, in caſe it ſhould not be returned.

It is adviſed, that from theſe maps, books, and papers, from general ſurveys, and incidental occurrences, are to be formed pocket regiſters of the farms; correſponding, in number and ſize, with the portable books of maps. One folio, or two oppoſite pages being appropriated to each farm; ſo as to ſhew, at one view, the name of the farm and its number of acres. The name of the tenant and the exiſting rent. The tenancy; and, if on leaſe, the term of expiry. Any extraordinary covenant of the leaſe. The number of cottages let with the farm.

The number of timber trees growing upon it.
——————— orchard trees growing upon it.
Alſo, the eligibility of the plan of the farm.
——————— the occupier of the farm.
——————— the preſent rent of the farm.
The ſtate of the buildings.
——————— the fences and gates.

The ſtate of the roads and water-courſes.
——— cultivation and live ſtock.
Likewiſe the repairs, more immediately wanted.
The improvements of which it is capable.
Together with ſhort notices or abſtracts of—
The agreements entered into with the tenant.
The permiſſions granted him; and
The injunctions delivered to him. With any other incident or occurrence reſpecting the farm or its occupier, that requires to be remembered: and with references to the books and papers which may pertain to the ſeveral particulars: thus having, at one view, a complete abſtract of the hiſtory, and preſent ſtate, of every farm; together with the particulars of attention which each will require. The trouble of forming an abſtract of this kind, or of renewing it, when filled, or in order to adapt it to the varying circumſtances of the ſeveral farms, is inconſiderable, compared with its uſes: which are not only obvious to theory, but are fully eſtabliſhed in practice. On returning to an eſtate, after twelve months abſence, he has generally found, that, by conſulting a regiſter of this ſort, and, through its means, making ſyſtematic enquiries, reſpecting the incidents that have occurred on the ſeveral farms, during his abſence, he has in this ſummary way, and before he entered upon a freſh view, became better acquainted, not only with the general intereſts, but with the more ordinary buſineſs, of the ſtate, than the acting manager, who had conſtantly reſided upon it, without ſuch a remembrancer: which ought not to comprehend tenanted farms, only; but ſhould compriſe woodlands, quarries, the demeſne, &c. in hand, as well as the more important improvements going on: each of which ought to have its ſeparate folio aſſigned it. It is ſtated that to a proprietor, or his confidential, who only goes over his eſtate occaſionally, ſuch an intelligent companion is eſſentially ſerviceable. He cannot profitably direct, nor ſafely adviſe with, an acting manager, or other agent, or officer of the eſtate, until he has conſulted ſo infallible an oracle. And the utility of ſuch a regiſter, while a proprietor is abſent from his eſtate, if he can be ſaid to be ſo, with ſuch a faithful mirror in his poſſeſſion, is too obvious to require explanation.

It is alſo recommended, that beſides thoſe written documents and regiſters, the office rooms of an eſtate ſhould be furniſhed with the mechanic inſtruments that are uſeful in its improvement and management: as earth borers, to ſearch for uſeful foſſils, &c. &c.; levelling inſtruments, for laying out roads and water-courſes, &c. &c. &c. Alſo models and drawings of draining mills, floodgates, farmſteads, buildings, implements, &c. &c. &c.

It is concluded that there are men who are loſing hundreds or perhaps thouſands annually by neglect or miſtaken frugality in the management of their eſtates, yet who will conſider this executive eſtabliſhment, and theſe forms and regulations of buſineſs, as unneceſſary and extravagant. Yet where the eſtates are very large, there can be no doubt theſe eſtabliſhments and regulations muſt facilitate the management of them in a very conſiderable degree, and of courſe be of eſſential advantage to thoſe who are the proprietors of them.

OFFICER, a perſon poſſeſſed of a poſt or office.

Great Officers *of the Crown*, or *State*, are the lord high-ſteward, the lord chancellor, the lord high-treaſurer, the lord preſident of the council, the lord privy-ſeal, the lord great chamberlain, the lord high conſtable, the earl marſhal, and lord high admiral. See Chancellor, Treasurer, Marshal, &c.

Officers *of Juſtice*, are thoſe who are entruſted with the adminiſtration of equity and juſtice in the courts thereof.

Officers, *Royal*, are thoſe who adminiſter juſtice in the king's name; as the judges, &c. See Judge.

Officers, *Subaltern*, are thoſe who adminiſter juſtice in the name of ſubjects. Such are thoſe who act under the earl marſhal, admiral, &c.

Officers *of Police*, are thoſe in whom the government and direction of the affairs of a community are inveſted. Such are mayors, ſheriffs, &c.

Officers *of War*, are thoſe who have command in the forces.

Theſe are either *general*, *field*, or *ſubaltern* officers.

Officers, *General*. See General *Officers*.

Officers, *Field*, are ſuch as have command over a whole regiment; ſuch as the colonel, lieutenant-colonel, and major.

Officers, *Subaltern*. See Subaltern.

Officers, *Commiſſion*, are ſuch as are appointed by the king's commiſſion.

Such are all from the general to the cornet and enſign, inclusive.

They are thus called in contradiſtinction to *non-commiſſioned* officers, as ſerjeant-majors, quarter-maſter-ſerjeants, ſerjeants, corporals, drum and fife-majors, who are nominated by their reſpective captains, and appointed by the commanding officers of regiments, and by them reduced without a court martial.

Officers, *Staff*, are the quarter-maſter-general, and the adjutant-general, who are ſtrictly ſaid to exiſt only in time of war; alſo, the quarter-maſters, adjutants, ſurgeons, and chaplains of regiments.

Officers, *Warrant*, are thoſe who have no commiſſions, but only warrants from ſuch boards or perſons as are authorized by the king to grant them.

Officers, *Sea*, or *officers of the marine*, are thoſe who have command in ſhips of war.

Officers, *Flag*. See Flag.

Officers *of the Houſhold*, are the lord ſteward, treaſurer of the houſhold, comptroller, cofferer, maſter, clerks of the green-cloth, &c. the lord chamberlain, vice-chamberlain, gentlemen of the privy and bed-chamber, gentlemen uſhers, grooms, pages, maſter of the wardrobe, of the ceremonies, &c. the maſter of the horſe, avenor, equerries, ſurveyors, &c. See Houshold. See alſo each officer in his proper article.

Officers, *Staff*, are ſuch as in the king's preſence bear a white ſtaff; and at other times, going abroad, have a white ſtaff borne before them by a footman bare-headed. Such are the lord ſteward, lord chamberlain, lord treaſurer, &c.

The white ſtaff is taken for a commiſſion; and at the death of the king, the officers break their ſtaff over the hearſe made for the king's body, and thereby diſcharge their inferior officers.

Officers, *Municipal*. See Municipal.

Officers, *Reformed*. See Reformed.

Officers *of the Mint*. See Mint.

Officers, *Signals for*. See Signal.

OFFICIAL, Officialis, in *Canon Law*, the biſhop's deputy or lieutenant; or an eccleſiaſtical judge appointed by a biſhop, chapter, abbot, &c. with charge of the ſpiritual juriſdiction thereof.

Of theſe there are two kinds: the one, as it were, vicar-general, of the church, exerciſing juriſdiction throughout the whole dioceſe, called by the canoniſts *officialis principalis*, in our ſtatute law the biſhop's chancellor.

There is no appeal from this court to the biſhop; his being eſteemed the biſhop's court.

The other, called *officialis foraneus*, as having his juriſdiction *foris, & extra civitatem*, is appointed by the biſhop when the dioceſe is very large; having a certain extent of territory aſſigned him, wherein he reſides.

This official has but a limited juriſdiction, though he have *univerſitatem cauſarum*, and exerciſe it in the biſhop's name. Our ſtatute-law calls him *commiſſary*.

The biſhops, eſpecially thoſe of large ſees, finding themſelves oppreſſed with a multiplicity of buſineſs, at firſt, diſcharged a part of it upon their archdeacons and prieſts, to whom they gave commiſſions revocable at pleaſure. Theſe are called *vicarii*, or *officiales*.

As we do not meet with this term any where before the conſtitutions of the *ſextus decretalium*, it is pretty apparent the cuſtom had not its riſe till the end of the thirteenth century.

In proceſs of time the function was divided into two; and the title official given to him with whom the biſhop entruſted the exerciſe of litigious juſtice; and that of vicars general, or grand vicars, to thoſe who had the voluntary juriſdiction.

The number of officials was ſoon exceſſively multiplied; and not only biſhops, but chapters and archdeacons, would have their officials.

The officials, by degrees, had drawn to their cognizance and juriſdiction moſt of the civil cauſes; till they were taken out of their hands by appeals, &c.

OFFICIAL is alſo uſed, in our laws, for a deputy appointed by an archdeacon, for the executing of his juriſdiction: and he ſtandeth in the ſame relation to the archdeacon as the chancellor doth to the biſhop.

OFFICIALTY, the court or juriſdiction of which an official is head.

The practice of officialties is now reduced into a little compaſs; and actions of promiſes, and diſſolutions of marriages, are the principal things tranſacted therein.

OFFICIARIIS *non faciendis, vel amovendis*, a writ directed to the magiſtrates of a corporation, requiring them not to make ſuch a man an officer, or to put one out of the office he hath, until enquiry is made of his manners, &c.

OFFICINAL, formed of *officina*, a *ſhop*, in *Pharmacy*, a term applied to ſuch medicines, whether ſimple or compound, as are required to be conſtantly kept in readineſs in the apothecaries' ſhops, to be mixed up in extemporaneous preſcriptions.

The *officinal ſimples* are appointed, among us, by the College of Phyſicians; and the manner of making the compoſitions is directed in their Diſpenſatory.

OFFICIO, *Suſpenſio ab*. See SUSPENSION.

OFFICIO, *Ex*. See EX *Officio*, INFORMATION, and OATH.

OFFICIO, *Quod clerici non eligantur in*. See QUOD.

OFFIDA, in *Geography*, a town of Italy, in the marquiſate of Ancona; 42 miles S.E. of Ancona.

OFFING, or OFFIN, in the *Sea Language*, that part of the ſea that is at a good diſtance from ſhore; where there is deep water, and no need of a pilot to conduct the ſhip into port.

If a ſhip from ſhore be ſeen ſailing out to ſeaward, they ſay ſhe ſtands for the offing. And if a ſhip having the ſhore near her, have another a good way without her, or towards the ſea, they ſay, that ſhip is in the offing.

OFFOLANKA, in *Geography*, one of the ſmaller Friendly iſlands. S. lat. 19° 35′. E. long. 185° 31′.

OFFRA, a town of Africa, on the Slave coaſt, where the Engliſh and Dutch have a factory; 3 miles S.W. of Jahim.

OFFRANVILLE, a town of France, in the department of the Lower Seine, and chief place of a canton, in the diſtrict of Dieppe; 3 miles S. of Dieppe. The place contains 1520, and the canton 13,286 inhabitants, on a territory of 190 kiliometres, in 34 communes.

OFF-RECKONING, in *Military Language*. See RECKONING.

OFF-SET, in *Gardening*, a ſort of ſucker, or ſmall young plant, iſſuing from the ſides of the main root of different ſorts of perennial plants, whether bulbous, tuberous, or fibrous-rooted, by means of which they are often readily increaſed.

The method of increaſing by off-ſets is applicable, in general, to all ſorts of bulbous and tuberous-rooted perennial plants, ſuch as tulips, anemones, &c. in which there are ſmall bulbs, or tubers, that on being planted out afford plants of exactly the ſame kind as thoſe from which they are taken, and which, after having one or two years' growth, flower, produce ſeed, and furniſh a ſupply of off-ſets in their turn.

In the vaſt tribe of fibrous-rooted perennial plants, moſt ſorts afford a progeny of this ſort, for propagating and perpetuating their reſpective ſpecies and varieties, both in the flowery kind, &c. and in ſome eſculents, but more conſiderably in the former; by which numerous ſorts of the moſt beautiful flowering perennials are multiplied. Off-ſets are, therefore, not only an expeditious and certain method of propagation, but one by which there is a certainty of having the deſired ſorts continued, whether ſpecies or particular varieties.

They have this advantage over ſeedlings, that the plants of the flowery kind often flower in one year; whereas ſeedling plants of the bulbous kinds are frequently four, five, and ſometimes ſix or ſeven years before they flower in perfection. By ſeedlings new varieties are principally gained, the roots of which furniſh off-ſets, by which they are increaſed.

The ſeparating off-ſets may be performed in ſome ſorts every year, in others once in two or three years, according to the ſorts, and the increaſe of off-ſets afforded by the main roots.

The proper ſeaſons for ſeparating or taking them off, in the bulbous and many tuberous-rooted plants, are chiefly ſummer and autumn, when they have done flowering, and the leaves are decayed, as at that period the roots of theſe ſorts, having had their full growth, aſſume an inactive ſtate, drawing little nouriſhment from the earth for a few weeks. It is alſo the only proper period for moving all the bulbous kinds in particular, both to ſeparate off-ſets and tranſplant the main roots, or to take them up for keeping a while. See BULB.

The roots ſhould be taken up in dry weather, if poſſible, and all the off-ſets ſeparated ſingly from the main bulb, &c. planting them in nurſery-beds, in rows ſix inches aſunder, by dibble, or in drills two or three inches deep, or in any other method that may be ſuitable. They ſhould remain a year or two, according to their ſize, in this ſituation to get ſtrength; then be tranſplanted, at the proper ſeaſon, where they are to continue, managing them as other bulbous and tuberous-rooted plants. See BULB and TUBER.

And the off-ſets of fibrous-rooted perennial plants, may either be ſlipped off from the ſides of the main roots as they ſtand in the ground, or the roots may be wholly taken up, and parted into as many ſlips as there are off-ſets properly furniſhed with fibres. In this ſort, the proper ſeaſon is the autumn, when their ſtalks decay, or early in the ſpring, before new ones begin to ſhoot forth; though ſome hardy

ſorts

ſorts may be ſlipped any time in open weather, from the autumn to the early ſpring, and others almoſt any time when they occur; planting them by dibble, the ſmaller ones in nurſery-beds, in rows ſix or eight inches aſunder, to have a year's growth; and the larger ones at once where they are to remain.

But in ſeveral ſorts of under-ſhrubby perennial plants that are capable of being increaſed by off-ſets from the bottoms, the proper ſeaſon for taking them off is the autumn and ſpring, or in the hardy kinds any time in open weather, during the autumn or early ſpring, planting them in nurſery-rows for a year or two, or till of proper ſize for the purpoſes they are deſigned for.

The off-ſets of ſucculent plants ſhould generally be ſlipped off in ſummer, and, previous to planting thoſe of the tender kinds, be laid on a dry ſhelf for ſome days, till the moiſture at bottom is dried up; then planted in pots of dry ſoil, and managed according to their different kinds and habits of growth. See Succulent Plants.

Off-ſets are never produced from annual plants of any kind.

But the particular management that is requiſite in the different kinds is more fully explained under the culture of the plant to which it belongs.

Off-sets, in *Surveying*, are perpendiculars let fall, and meaſured from the ſtationary lines, to the hedge, fence, or extremity of the incloſure.

Off-set *Staff*, a rod, or ſtaff, of any convenient length; for inſtance, of ten links of the chain.

This ſtaff is divided into ten equal parts. Its uſe is for the ready meaſuring the diſtances from the ſtation line of things proper to be repreſented in a plan. See Chain.

OFF-TRACING. See Calquing, Counter-*Drawing*, Designing, and Pentagraph.

OFF-WARD, in the *Sea Language*, the ſame with contrary to the ſhore: thus they ſay, *the ſhip heels off-ward*, when, being aground, ſhe heels towards the water-ſide; *the ſhip lies with her ſtern to the off-ward, and the head to the ſhore-ward*, when her ſtern is towards the ſea, and head to the ſhore.

OFVANAKER, in *Geography*, a town of Sweden, in the province of Helſingland; 37 miles W. of Soderhamn.

OFVERBY, a town of Sweden, in Weſt Bothnia; 32 miles N.W. of Pitea.

OGBUCKTOE, a ſettlement on the E. coaſt of Labrador. N. lat. 55° 55′. W. long. 60°.

OGDEN, Samuel, in *Biography*, a learned divine of the church of England, was born at Mancheſter in 1716. Having been inſtructed in grammar-learning at the free-ſchool in his native town, he was entered of King's college, in the univerſity of Cambridge, from which houſe he removed to St. John's college in the year 1736. He took his degree of B. A. in 1738, and in the following year was elected fellow of his college. In 1740 he received deacon's orders; and ſoon after was admitted to the degree of M. A. and ordained prieſt. Three years after this he was elected maſter of the free-ſchool at Halifax in Yorkſhire, which he retained till the year 1753, when he went to reſide at the univerſity of Cambridge. At the firſt Commencement, after his return, he took the degree of doctor of divinity; and on that occaſion recommended himſelf ſo ſtrongly to the duke of Newcaſtle, who was chancellor of the univerſity, by the exerciſe which he performed, that his grace preſented him to the vicarage of Damerham in Wiltſhire. In 1764 he was appointed Woodwardian profeſſor, and in 1766 was preſented to the rectory of Lawford in Eſſex, and alſo to that of Stansfield in Suffolk. Dr. Ogden had acquired great celebrity in the univerſity by the popularity of his preaching, and in 1770 he publiſhed a volume of "Sermons on the Efficacy of Prayer and Interceſſion; which being very favourably received, he printed, in 1776, another volume on the ten commandments, to which, in the following year, he added a ſecond, "On the Articles of the Chriſtian Faith." He died in the year 1778, in the ſixty-ſecond year of his age. His ſermons are ſhort, animated, and ſtriking. Sometimes the author riſes to the ſublime, and ſometimes he is diſtinguiſhed by beautiful ſtrokes of pathos. His method is deſultory; his reaſoning is not always perſpicuous; and his ſtyle, though correct and clear, is too conciſe and abrupt to be recommended as a model of good compoſition on general ſubjects. In the year 1780, Dr. Halifax publiſhed a new edition of his ſermons in two volumes octavo, with a memoir prefixed, to which the reader is referred for further particulars.

OGEE, or Og, in *Architecture*, a moulding, conſiſting of two members, the one concave, the other convex, the ſame with what is otherwiſe called *cymatium*.

Vitruvius makes each member of the ogee a quadrant of a circle; Scamozzi, and ſome others, make them ſomewhat flatter, and ſtrike them from two equilateral triangles.

The figure of the ogee bears ſome reſemblance to that of an S.

Ogee, in *Gunnery*, an ornamental moulding in the ſhape of an S, uſed in guns, mortars, and howitzes.

OGEECHEE, in *Geography*, a river of America, in Georgia; 18 miles S. of Savannah river, the courſes of which rivers are parallel to each other. It riſes near the Appalachian mountains, and diſcharges itſelf into the ſea, oppoſite to the N. end of Oſſaban iſland; 18 miles S. of Savannah.

OGELSTRÖMEN, a river of Sweden, which riſes in the mountains bordering on Norway, and runs into the Angermann, near Liden.

OGENDOW, a town of the Birman empire; 10 miles S.W. of Pegongmew.

OGERSKOI, a town of Ruſſia, in the government of Perm; 52 miles W. of Perm.

OGESIMA, a ſmall iſland of Japan, in the ſtrait between Niphon and Xicoco.

OGGIANO, a town of Italy, in the department of the Lario; 11 miles E.S.E. of Como.

OGHAM, or Ogum *Characters*, among the Iriſh antiquaries, are certain characters found on monuments, and on old writings of a cryptographic, or ſtenographic nature: theſe antiquaries contend that their origin is very remote, and that their exiſtence proves the juſtice of the claim which the Iriſh make to the uſe of letters at a period long antecedent to that when they were firſt introduced into the other Weſtern nations of Europe. In giving an account and deſcription of the Oghams, therefore, it is propoſed to comprehend a ſhort diſcuſſion on this important point of antiquarian reſearch, which, if we are not miſtaken, will lower the claims of the Iriſh to the level of juſtice, truth, and common ſenſe. Coolneſs and ſobriety of judgment are of the firſt importance and neceſſity in every antiquarian inveſtigation, but they are moſt indiſpenſably neceſſary, where objects of Celtic antiquarianiſm are involved.

According to the moſt accurate and beſt informed writers on the ſubject of Iriſh characters, there were three kinds of Ogums; firſt, Ogum beith, where *b h*, or the Iriſh letter *beith*, the firſt conſonant, is uſed inſtead of the vowel *a*. To this Ogum, the name of Ogum conſoine is given.

Harris,

Harris, in his edition of ſir J. Ware's Antiquities of Ireland, gives the following example of it.

a	*e*	*i*	*o*	*u*
bh	*fc*	*ng*	*dl*	*ft*

Sometimes conſonants were ſubſtituted for diphthongs, as in the following example:

ae	*ia*	*ua*	*io*	*oi*
mm	*ll*	*bb*	*cc*	*pp*

The ſecond kind was called Ogum coll, or the Ogum formed out of the letter *c*, to which the name of *coll* is given in the Bethluiſnion alphabet: in this kind of Ogum the letter *c* is ſubſtituted for all the vowels, diphthongs, and triphthongs, repeated, doubled, and turned in various ways. The following are examples of this ſpecies of Ogum:

a	*e*	*i*	*o*	*u*
c	*cccc*	*cccc*	*cc*	*ccc*
ea	*ia*	*oi*	*io*	*ua*
ↄ	ↄↄ	ɔ	ↄ	ↄↄ

Before proceeding to the conſideration of the third kind of Ogum, it may be proper to offer a few remarks on the two ſpecies which have been juſt deſcribed.

It is ſufficiently obvious that their antiquity cannot be great; and that the uſe of them was by no means confined to the Iriſh nation, even at the earlieſt period to which it can be traced. We are informed by Suetonius, in his "Life of Julius Cæſar," and by Dio, that that emperor, when he wrote to any one what he wiſhed to be kept ſecret, always employed the fourth letter after that which he ought to have uſed; as *d* for *a*, *e* for *b*, &c.; and Suetonius and Iſidorus relate that Auguſtus had alſo a cypher which he employed in his writings, when he wiſhed them to be kept ſecret, uſing the letter following that which he ought to have employed, as *b* for *a*, and *c* for *b*: ſometimes he varied his cypher; for the letter *z*, he uſed *a a*. Indeed this cypher mode of writing, to which the two ſpecies of the Iriſh Ogums, which we have deſcribed, evidently belong, was not only well known to the Greeks and Romans, but was employed by them in various forms, and reduced to a clear and regular ſyſtem. The ancient notes or cyphers were comprehended under three heads: 1. The hieroglyphical, where the object to be underſtood was expreſſed by a ſymbol, as where a circle was put to expreſs the ſun. 2. The Tironian notes, which were ſo called from Tiro, the freedman of Cicero; in theſe a cypher or character had the power of many letters. Theſe are of great antiquity; they appear to have been borrowed by Ennius from Eaſtern and Greek archetypes, to have been greatly augmented, and uſed with great ſkill by Tiro, and finally to have been digeſted and reduced into a regular ſyſtem by Seneca. 3. Sigla, or literary ſigns; theſe were merely verbal contractions, which are found on marbles, coins, and medals. The Roman laws and proceedings were contained in theſe ſigla; and, as ſome antiquaries are of opinion, alſo in the ſecond ſort of cypher. Cicero certainly ſtates that the forms of proceſs in the Roman law were written in ſecret marks (notis); and this expreſſion points out rather the ſecond than the third ſpecies of cypher. So much intricacy and obſcurity had ariſen from the uſe of theſe cryptogamic characters, that Tribonianus, who compiled the Juſtinian code, was frequently at a loſs to diſcover their meaning; and in A. D. 533, their uſe was forbidden by an imperial edict.

Cyphers of one or other of theſe kinds were uſed wherever a Roman ſtation or colony was planted; and they were ſoon adopted by the barbarous nations whom the Romans had ſubdued. Theſe nations, or rather their prieſts, to whom alone, at this period, the knowledge of letters was confined, not only adopted the general mode of the Romans, of ſubſtituting one character for another, and thus forming a cryptographic alphabet, but they alſo mixed Roman notes and characters with their original alphabets: hence we find in the ſeventh, eighth, and ſubſequent centuries, ſo many alphabets among the Gothic and Celtic tribes, uncouth in their figure, confuſed in their order, and barbarous in their name. There is ſufficient evidence to prove that among the principal nations of both theſe tribes, their reſpective primitive alphabets were employed for ſuppoſed magical purpoſes; that a knowledge of the power and aſcribed virtue of the letters, of which it was formed, was confined to a certain order of men, by whom it was employed for theſe purpoſes; and that this order of men, after the common alphabet, by the progreſs of knowledge, would no longer ſerve theſe purpoſes, again clothed it in myſtery by the intermixture of characters borrowed from their Roman conquerors.

Cryptographic modes of writing, exactly ſimilar to the two ſpecies of Iriſh Ogums which have been deſcribed, were practiſed in all the northern countries of Europe. In the Icelandic Edda at Upſal, is an example of the firſt ſpecies of Ogum, or the Ogum conſoine, where, inſtead of the vowel, the conſonant which follows next in the alphabet is placed, as

"Dfxtfrt ſcrkptprks bfnfdkth skt pmnkbxs hprks."

Here, inſtead of *a*, *e*, *i*, *o*, *u*, *y*, the conſonants *b*, *f*, *k*, *p*, *x*, and *z* are placed, ſo that it reads thus;

"Dextera ſcriptoris benedicta ſit omnibus horis."

A ſimilar cypher was uſed by the Anglo-Saxons.

In theſe two ſpecies of Ogums, therefore, there is no trace either of antiquity or peculiarity: the third ſpecies will require a more detailed conſideration.

This third ſort is the Ogum *croabh*, or the virgular Ogum, which is thus deſcribed by Mr. Aſtle, in his "Origin of Writing," page 179, 2d edition. "It was compoſed of certain lines or marks, which derive their power from their ſituation or poſition, as they ſtand in relation to one principal line, over or under which they are placed, or through which they are drawn; the principal line is horizontal, and ſerves for a rule or guide, whoſe upper part is called the left, and the under ſide the right; above, under, and through which line, the characters or marks are drawn, which ſtand in the place of vowels, conſonants, diphthongs, and triphthongs." In a ſpecimen which he gives of Ogham writing of this kind, taken from J. Ware's Antiquities of Ireland, the cypher is very ſimple. The horizontal line is the principal, or maſter line, as it is called; and the perpendicular and diagonal lines, above, below, and through the horizontal line, ſtand for twenty letters, in four diviſions of five letters each; the conſonants are repreſented by the firſt fifteen, and the vowels by the laſt five: arbitrary marks are ſubſtituted for the diphthongs and the letter Z. Colonel Vallancey, in his Iriſh grammar, gives a ſpecimen of this kind of Ogum, in which the cypher is different from that given by ſir J. Ware, the diagonal lines ſtanding for the vowels.

That, however, there is great uncertainty reſpecting the cypher of this kind of Ogum, is evident, from the account that colonel Vallancey gives of it in another place. In a paper of this gentleman, in the 7th volume of the Archæologia,

Archæologia, to which we ſhall afterwards have occaſion to advert more at length, he confeſſes that he had ertoneouſly ſaid that the Ogum characters were marked by certain ſtrokes ſtanding perpendicularly on an horizontal maſter line; but from ancient MSS. he found that the maſter line was drawn perpendicular, and the characters marked by ſtrokes perpendicular to it, over the right and left; yet in the ſame paper he gives another manner of writing the Ogum, in which horizontal ſtrokes are drawn on each ſide of a perpendicular line. Other writers give ſpecimens of circular Ogums; ſo that, if the Iriſh antiquaries are to be credited, theſe are, 1ſt, the circular mode of drawing the Ogum; 2d, the Ogum on a horizontal maſter line with perpendicular ſtrokes; 3d, the Ogum on a perpendicular maſter line with perpendicular ſtrokes; and 4th, the Ogum on the perpendicular maſter line with horizontal ſtrokes. Whatever may be the antiquity of this ſpecies of cryptographic writing, it is evident that the mode of interpreting it muſt be very looſe and ambiguous, and that no dependance can be placed on the meaning of the inſcriptions which are found in it.

But this ſpecies of Ogum is repreſented by the Iriſh antiquaries, not only as cryptographic, but as ſtenographic: how little it deſerves the latter character, may be eaſily made obvious; it requires fifteen lines or ſtrokes to expreſs the firſt five letters of the alphabet, or fifty-one for the eighteen elements of the Iriſh language. Yet this is the Ogum which colonel Vallancey aſſures us, in his Iriſh grammar, "the Iriſh antiquaries preſerved as a piece of the greateſt value, and that it was penal for any but the Druids to ſtudy or uſe it."

Sir James Ware is the firſt author who mentions the Ogum croabh, or virgular Ogum (Antiquities of Ireland, xi. 20.); he ſays, that he was in poſſeſſion of a thick MS. written entirely in this Ogum. Keyſler mentions, that in his time (1720) the earl of Carnarvon had in his library a MS. on this kind of writing, and Aſtle refers to a MS. preſented to the Britiſh Muſeum by the late Rev. Dr. Milles, dean of Exeter, preſident of the Society of Antiquaries at London, which had formerly been in the library of Henry, earl of Clarendon; among the tracts of this MS. volume, there is one entitled "(Anomymi Hiberni) Tractatus de variis apud Hibernos veteres occultis ſcribendi formulis ſeu artificiis, Hibernice Ogum dictis." From this tract, Aſtle has given a plate of the different kinds of virgular Ogums.

Notwithſtanding the direct and poſitive authority of ſir J. Ware, and the prediſpoſition of colonel Vallancey to give credit to any thing which favours or proves the claims of the Iriſh to high antiquity, the latter gentleman, for a long time, according to his own confeſſion, concluded, too haſtily, that "both ſir James and himſelf had been impoſed upon by modern bards, and that no ſuch characters ever exiſted in Pagan times." Archæologia, vii. 277.

This Ogum the Iriſh ſeanaches or antiquaries repreſent as the alphabetical character, which was regularly uſed as ſuch, and not as a cypher, by their Pagan anceſtors long before the time of St. Patrick, to whom the introduction of letters into Ireland is generally aſcribed. It is rather ſurpriſing, therefore, that before it was mentioned and deſcribed by ſir James Ware, it ſhould neither have attracted their notice, nor been the object of their reſearches. M'Curtin, a hereditary antiquarian of the county of Clare, who died about the middle of the ſeventeenth century, aſſerts in his Iriſh grammar, that he had met with no leſs than thirty-two ways of writing this Ogum, "ſo common and well known (obſerves Mr. O'Halloran, in his Hiſtory of Ireland, vol. i. p. 68.) was it *even then*." But colonel Vallancey is diſpoſed to doubt whether theſe could be all alphabetical Oghams; and referring to the plate which Mr. Aſtle has given, in his work on the origin and progreſs of writing, of ſuch Ogums as he had diſcovered in Iriſh MS. in Ireland, he gives it as his opinion, that only one is ancient; "ſome," he adds, "are the inventions of modern bards, but the moſt are ſcales of *Proſodia*, originally drawn in circles, and from thence formed into right lines, at pleaſure, to the number of 150 different ſcales, as fully deſcribed in an ancient MS in my poſſeſſion." (Archæologia, vii. 227.) From not attending to this circumſtance, the Iriſh bards fell into the miſtake, that the ancient Iriſh had ſo many different alphabets. This opinion, however, is directly oppoſite to that which is maintained by O'Flaherty, who, on the authority of Duald Firbiſs, whom he characteriſes as "the only pillar and guardian of Iriſh antiquities, while he lived; and whoſe death was an irreparable loſs to any further improvement on them," maintains that there were actually different forms of Ogum characters, of this ſpecies, to the number of one hundred and fifty; of ſeveral of which Duald Firbiſs was in poſſeſſion; and of which he wrote an account to O'Flaherty, and "of Croabh Ogham, *i. e.* virgean characters." O'Flaherty's Ogygia, tranſlated by the Rev. James Hely, vol. ii. p. 99.

Theſe various and contradictory accounts reſpecting the nature of the virgean Ogum, in conjunction with the circumſtance, that, if the account of its nature, origin, and uſe, as given by the Iriſh antiquaries, had been correct and well founded, it muſt have been often employed both in MS. and on ſtones, altars, and cromlechs, yet it could not be traced by the indefatigable zeal and perſeverance of colonel Vallancey, certainly would not eaſily or readily have yielded to a belief in its high antiquity and almoſt ſacred character, in the mind of any perſon not deeply tinctured with credulity. We have already mentioned, that colonel Vallancey was diſpoſed, at one time, to doubt of the exiſtence of ſuch an Ogum; but the vacillation of his mind, or rather his wiſh to believe, became apparent in his Iriſh grammar, where he aſks, with a ſtrong emphaſis, "ſhall we doubt the authority of ſir James Ware? ſhall we diſbelieve our eyes, when we behold Ogum inſcriptions on many remains of antiquity?" From this paſſage in his Iriſh grammar (p. 7.), it might naturally be inferred, that theſe inſcriptions had been ſeen by colonel Vallancey himſelf; no ſuch thing; for four pages afterwards, he ſays, "we are ſorry it is not in our power to quote any paſſages in our Druidic Ogum, *ſuch books having not fallen into our hands.*" Now, it can ſcarcely be maintained that there is no contradiction here, if in the paſſage firſt quoted, he meant to aſſert, that he himſelf had ſeen Ogum *inſcriptions*, becauſe in the other paſſage, he ſays, no *books* containing the Druidic Ogum had fallen into his hands: for the purpoſe of giving an example (which he laments he cannot give) the Ogum inſcriptions on the remains of antiquity, would have ſerved as well as paſſages or ſpecimens from Ogum MSS.

As, however, the very high antiquity of the virgean Ogum could not well be proved, unleſs it were found on ſome of the Iriſh monuments or altars, the reſearches of the Iriſh antiquarians were directed to them. About the beginning of the eighteenth century, a monument at New Grange, in the county of Meath, a ſhort diſtance from the river Boyne, was diſcovered: ſeveral of the rude ſtones which compoſe it are decorated with a variety of devices, circular, zigzag, and diamond-ſhaped; many of the ſtones on each ſide of the *adel* have ſimilar rude marks upon them, and one of them has ſpiral zigzags. Soon after the diſcovery of this monument, the Iriſh antiquaries proclaimed to the world, that they had found the Ogham characters; but no reſemblance to letters or characters can be traced by impartial

partial and cool obſervers; and ſir Richard Colt Hoare, in his Journal of a Tour through Ireland, expreſsly ſtates, that the marks which he obſerved on many of the ſtones bore very little reſemblance to letters, and a great ſimilarity to the ornaments that he had found in the ancient Britiſh urns diſcovered under the tumuli in Wiltſhire (p. 256.); and Mr. Edward Llhwyd, who yielded to no man in zeal for the antiquities of the Celtic tribes, while he united an uncommon degree of coolneſs and judgment with his antiquarian fondneſs and knowledge, though he deſcribes the monument at New Grange very particularly, does not even conjecture, that the rude carvings on the ſtones were letters or Ogum characters.

Colonel Vallancey, in the ſecond volume of his *Collectanea*, gives engravings of two croſſes, ſtanding in the church-yard of Caſtle Dermot, in the county of Kildare, with inſcriptions on them, which he regards as ſpecimens of the Ogum characters; theſe croſſes are ſuppoſed to bear the date of the tenth century. But it may be remarked, in the firſt place, that the claim of theſe inſcriptions to the Ogum character is very doubtful; and ſecondly, even allowing that they are in that character, and of the age aſſigned to them, the antiquity of this character does not riſe nearly up to the period of Iriſh Paganiſm; and, therefore, no proof can be grounded on theſe croſſes for the Druidic origin or uſe of the virgean Ogum; and it is not meant to be denied, that ſubſequently to the introduction of Chriſtianity, it was employed in Ireland; and probably on monuments in the tenth century, though this ſir Richard Colt Hoare is ſtrongly diſpoſed to doubt.

In the Iriſh grammar of colonel Vallancey, a paſſage is quoted from an Iriſh MS. which ſtates, that "Fiacra was mortally wounded at the battle of Caonry, his funeral leacht or ſtone was erected, and on his tomb was inſcribed his Ogum name." (P. 7.) But though this appears ſufficient evidence and guide to lead to the diſcovery of an ancient Ogum inſcription (if the monument were ſtill in exiſtence), it does not ſeem that the tomb of this hero was ſought after by any Iriſh antiquary. At laſt, about the year 1780, a diſcovery was made, which ſatisfied colonel Vallancey, and all true Iriſh antiquaries, that the virgean Ogum was a regular alphabetical character, and that it exiſted, and was in general uſe, long before the coming of St. Patrick into Ireland; having thus, in their opinion, traced back the virgean Ogum to an antiquity higher than the era of the introduction of Chriſtianity into Ireland, they ſuppoſed they had advanced a conſiderable ſtep towards putting it beyond a doubt that its origin was Druidic. This ſuppoſed diſcovery was made by Mr. O'Flanagan, at that time a ſtudent of Trinity college, Dublin; we ſhall give the ſubſtance of what he ſays, in a paper read before the Royal Iriſh Academy, on the 19th December 1785, reſpecting the circumſtances which led to the diſcovery; and the interpretations of the inſcription which he offers.

Being perfectly acquainted with the various dialects of the Iriſh language, he amuſed himſelf with reading many of the legends both in proſe and verſe; in one of the latter, aſcribed to Oſſian, he met with the following paſſage: "The fierce and mighty Conan was not in the deſperate battle of Gabhra; for in May, the preceding year, the dauntleſs hero was treacherouſly ſlain by the Fenii of Fin, at an aſſembly met to worſhip the ſun: his ſepulchral monument was raiſed in the north-weſt! His wailing dirge was ſung, and his name is inſcribed in Ogum characters on a flat ſtone, on the very black mountain of Callan."

The firſt object which Mr. O'Flanagan diſcovered on mount Callan, which is about nine miles from Ennis, was a Druid altar; but this had not the ſmalleſt traces of any characters appearing on it; though it might have been ſuppoſed, that here, if any where, the Druidic Ogum would have been engraved. At laſt his zeal was rewarded; about a mile north-eaſt of the altar, a cottager informed him, that there was a ſtone, "not unlike a tomb-ſtone, having ſtrokes engraven thereon, very unlike letters." As Mr. O'Flanagan had neglected to take his grammar with him, he was not thoroughly prepared to collect the entire ſenſe of the inſcription; but from the rules in his memory, he decyphered it in the following manner: "Fan licſi ta Conan Colgac cos-fador;" "beneath this ſtone is Conan the Fierce, the Long-legged." On his return home, and conſulting the rules given by colonel Vallancey, in his grammar, for decyphering the Ogum characters, he found the meaning to be "Fan li difica Conan Colgac cos-obmda;" beneath this ſtone is laid Conan the Fierce, the Nimble-footed. Had Mr. O'Flanagan reſted contented with this improved verſion, he could not have afforded room for entirely diſbelieving the exiſtence of Ogum characters on this monument; but anxious to prove that this kind of writing was not only very ancient, but had a wonderful ſuperiority in the comprehenſiveneſs of its meaning, to any ſet of alphabetical or ſtenographic characters known, he has afforded grounds for moſt rational and complete ſcepticiſm.

It appears from this gentleman's account, that even with the aſſiſtance of the rules contained in colonel Vallancey's Iriſh grammar, for decyphering the Ogum character, he found ſome difficulty in making out the meaning of the inſcription on this monument; and while he was muſing over it, Mr. Burton, a friend who had accompanied him to Callan, "calling to mind that the Phœnicians, from whom the Iriſh derived their origin, generally write from the right hand to the left, took the letters backwards; *i. e.* in a contrary direction from that in which we had decyphered them." By this contrivance a ſecond reading was found, which, wonderful to relate, had not only made good ſenſe, and had reference to the ſame hero, but proved a continuation of the firſt reading. A common antiquarian would have been content with theſe two readings; not ſo Mr. O'Flanagan. On his arrival in Dublin he conſulted the book of Ballemote, from which he found there were different ſcales of the Ogum character, in each of which the number of ſimilar lines, on whatever ſide drawn, did not exceed five. After having made himſelf perfectly acquainted with this ſcale, he again applied to the ſtudy of the inſcription; when he drew from it no fewer than five different meanings: the firſt has been already given; the ſecond is, "Na flida nica Conan Colgan cos-obmda;" obſcure not the remains of Conan the Fierce, the Nimble-footed: the third is, "Adm bo ſocc agloc fan oca cifa dil Naf;" long let him lie at eaſe on the brink of this lake, beneath theſe hieroglyphics, darling of the Sacred: the fourth is, "Adm bo ſocc ag loc na foc a cina del fan;" long let him lie at eaſe on the brink of this lake, who never ſaw his faithful clan depreſſed; the fifth and laſt is, "Almho Coſſag dos ta cu os aſit a lid cuat;" hail with reverential ſorrow the drooping heath around his lamentable tomb. On this inſcription, thus decyphered, ſo very pregnant with meaning, Mr. O'Flanagan makes the following remarks: "When all theſe various readings are united, there appears a rational beginning, continuation, and concluſion of the ſame ſenſe. But what is ſtill more remarkable, the number of readings is the limit of the number of lines in the Ogum ſcale. The whole is in the ſtile and manner of the ancients, deſcriptive both of the man and the place; and though the language be very ancient, yet it is equally familiar and eaſy to ſuch as are well

well verſed in the ſeveral idioms and dialects of the Iriſh language."

Before proceeding to offer any remarks on the Callan inſcription, and on Mr. O'Flanagan's interpretation of it, we ſhall give the rules on which he contrived to bring out of it ſuch copiouſneſs of meaning: had theſe rules been laid down in the Iriſh grammars, and in treatiſes on the decyphering of the Ogum character, and had they been illuſtrated and confirmed by examples of undoubted antiquity, the inſcription on the Callan monument, as interpreted by Mr. O'Flanagan, might have been received as a ſpecimen of the Druidic Ogum, and as a proof, not only of the great antiquity, but of the wonderful ingenuity of this mode of writing: but when we ſhall find that the rules which Mr. O'Flanagan followed in interpreting the inſcription were in the higheſt degree arbitrary, and which, if extended, might have elicited fifty meanings inſtead of five, and would go to deſtroy all certainty in language, our doubts reſpecting the Ogum character will be ſtrengthened, and by no means removed by the Callan inſcription.

In order to get the firſt and ſecond meanings, the inſcription muſt be decyphered from the broad to the narrow end of the ſtone, or from left to right; the letters F and N being interchanged, whenever they occur, as the ſenſe ſhall direct: the third and fourth readings are found by taking the two former backwards (here the proceſs is from right to left, commuting the letters F and N as before.) The fifth and laſt reading is made out "by decyphering the Ogum line from the ſmall to the broad end of the ſtone, changing its poſition that the proceſs may be from left to right. In this, neither of the letters F or N occurs, and therefore it admits of no further readings." The reaſon which led Mr. O'Flanagan to the commutation of the letters F and N, is equally whimſical and unfounded with every other ſtep in the proceſs of interpreting this inſcription. "This commutability of the letters F and N depends on a circumſtance peculiar to the Iriſh alphabet, it having two different arrangements: one of which begins with B, L, N, and is called Beithluiſnuin, and the other with B, L, F, and called Beithluisfearn; the latter is *peculiar to the Ogum ſyſtem*, but when it is neceſſary for the conſtruction, it does not totally reject the former, which was the alphabet in common uſe, until Greek and Roman literature viſited this country, and made the Iriſh arrange their alphabet, as far as it extended, conformable to their own." And in a ſubſequent page he obſerves, "obſcurity, and to contain much within a narrow compaſs, was the purpoſed end and object of the Ogum; for from the conſtruction it contains much within a ſmall ſpace, and is ultimately founded on an alphabet of different characters, which is evident even from the explication of the inſcription before us, wherein the letters F and N (which are ſeverally repreſented by three and five perpendicular ſtrokes below the horizontal maſter line) are commutable, a property which they have not in any other part of our language; this commutation depending, as has been already obſerved, on the two different arrangements of the Iriſh alphabets: and thus it is left to the reader's choice, to which of the two letters F or N, he will apply either of the aforeſaid marks, but the ſenſe will always direct him to the proper mode of application." Tranſactions of the Royal Iriſh Academy for the year 1787, vol. i. Antiquities, p. 12.

Having thus given a detailed account of the celebrated Callan inſcription, of the interpretation which Mr. O'Flanagan has given of it, and of the rules which he has followed in decyphering it, we ſhall offer a few remarks, which, if we are not miſtaken, will not only go far to diſprove the exiſtence of an Ogum inſcription on this monument, or, granting its exiſtence, the accuracy of the interpretation put upon it; but alſo the claim of the Ogum character or alphabet to Druidic invention or antiquity.

In the firſt place, Dr. Ledwich, in his Antiquities of Ireland, very pertinently and fairly aſks, "Can it be imagined that the Callan inſcription has ſtood almoſt 1500 years (for the death of Conan is ſaid to have happened in the year 295), in a naked and wild ſituation, uninjured by the tooth of time, and all the viciſſitudes of a variable climate? That the great Atlantic ocean, and its briny atmoſphere, have had no influence on this rock, and ſo far from pulveriſing its ſurface, have rendered it uſeful for vegetation?" (P. 341.) Mr. O'Flanagan, indeed, in a note to his paper (p. 14.), informs us, that from the hard texture of the ſtone the inſcription is perfectly legible; but in another place he ſays, that the ſtones of this monument are of the ſame kind as thoſe of the Druidic altar, and thoſe he expreſsly deſcribes as "gritty," certainly not a kind of ſtone likely to preſerve entire the inſcription on its ſurface. It ſhould alſo be recollected, that a ſingle eraſure of one of the cyphers, or even of part of one of the cyphers, would have been ſufficient to deſtroy, or eſſentially to alter, the meaning of any Ogum inſcription.

In the ſecond place, two engravings are given of the Callan inſcription, both by Mr. O'Flanagan; one in the ſeventh volume of the Archæologia, p. 281; and the other in the firſt volume of the Tranſactions of the Iriſh Academy (Antiquities, p. 16.) Now whoever will compare, even in a curſory and ſuperficial manner, theſe two engravings, will find that they materially differ.

In the third place, Mr. O'Flanagan in his paper in the Iriſh Tranſactions, as has been already noticed, ſays, that his firſt reading, "Fan licſi ta Conan Colgac cos-fada," was made out before he had an opportunity of conſulting colonel Vallancey's grammar, and that it was afterwards found to be erroneous; whereas, in his letters to that gentleman, publiſhed in the ſeventh volume of the Archæologia, he expreſsly ſays, "by the rules given for the Ogham croab in M'Curtin's dictionary, and your grammar, I decypher this inſcription in the following manner," *i. e.* exactly in the manner which in his paper in the Iriſh Tranſactions he declares to be erroneous, and to have been the reſult of his decyphering it from memory.

In the fourth place, though a general remark has been already offered on the very arbitrary and unfounded rules, by which Mr. O'Flanagan proceeded in the interpretation of the inſcription, yet a more detailed examination of them may be proper. Mr. O'Flanagan confeſſes that "the diſcovery of the true ſenſe of the inſcription was principally owing to the ingenious thought of Mr. Burton, with reſpect to the reading backward; which, whether it affects the ancient literary ſyſtem of this country or not, at leaſt was inſtrumental in exciting me to the ſearch, which I ſhould otherwiſe have been apt to neglect; for finding one ſenſible reading, it is probable I ſhould not have thought of tracing it farther *than the rules in our grammars might direct*, and thoſe I find are totally inſufficient." (Iriſh Tranſactions, Antiquities, p. 16.) Here is a full and complete acknowledgment, that his mode of interpreting the inſcription was entirely arbitrary; and as the rules laid down in the grammars for the interpretation of the virgean Ogum, muſt be ſuppoſed to have been drawn from all the known varieties of this mode of writing, Mr. O'Flanagan's method muſt be regarded, not only as arbitrary, but as utterly unfounded

and unſupported. It is even deſtitute of any ſupport which might be derived from the ſuppoſed Phœnician origin of the Iriſh nation; for though this circumſtance, if well eſtabliſhed, might render it highly probable that the Iriſh would imitate their anceſtors in writing from the right-hand to the left, it could never juſtify the concluſion, that becauſe the Phœnicians wrote in this manner, therefore the Iriſh, in the third century, both retained this mode, and followed the weſtern mode of writing from the left-hand to the right.

Mr. O'Flanagan appears to have been ſuſpicious of the foundneſs of the opinion ſuggeſted by his friend Mr. Burton; and therefore applied to Mr. O'Connor, an "antiquarian of credit," who decides very peremptorily on the ſubject.

"That the Mileſian family," ſays he, "imported letters into Ireland, and that their anceſtors learned them from the Phœnicians, I am certain; and Mr. Burton judged well in averring that our earlieſt ſcribes wrote from the right-hand to the left, but they changed to the more commodious manner of writing from the left to the right, and laid aſide the uncouth crooked character of the Phœnicians, when the beautiful Greek and Roman characters were made known here in the fourth and fifth centuries." P. 15.

On the Mileſian origin of the Iriſh nation, and on the Phœnician origin of the Mileſians, it is not here neceſſary to ſay any thing; but on the other poſitions, or rather aſſertions, of Mr. O'Connor, a few remarks may be offered. He aſſerts that the earlieſt Iriſh ſcribes wrote from the right-hand to the left: in proof and defence of this aſſertion he does not offer a ſingle argument or authority; and indeed that would have been impoſſible, for all the Iriſh MSS. are written from the left-hand to the right, and there is not the ſmalleſt trace of any evidence that they ever wrote in any other manner. It can hardly be expected, therefore, by the moſt warm admirer of Mr. O'Connor's antiquarian knowledge, that his bare and unſupported aſſertion ſhould be admitted againſt all other evidence on this ſubject. But Mr. O'Connor, in his zeal to make out his point, unfortunately proves too much; according to him, the Iriſh ſcribes changed to the more commodious mode of writing from the left to the right, at the ſame time that they adopted the beautiful Greek and Roman characters, *i. e.* "in the fourth and fifth centuries." But if this new mode of writing was not adopted till the fourth or fifth centuries, what becomes of the genuineneſs of the inſcription on the monument of Conan, who is ſaid to have been buried A.D. 295. Mr. O'Flanagan cannot ſurely expect that all his modes of reading and interpreting the inſcription ſhould be allowed him, if he agrees with Mr. O'Connor that the earlieſt ſcribes wrote from the right to the left-hand, and that the other mode was not brought into uſe till the fourth and fifth centuries; he muſt either give up the genuineneſs of the inſcription, or two of his modes of reading it. If, on the other hand, he adheres to the general opinion, and to the evidence of all MS. and other inſcriptions, that the uſual mode of writing was from the left to the right, he muſt loſe the advantage of the third and fourth readings; and, conſequently, the comprehenſiveneſs of the inſcription which he ſo much admires will be conſiderably curtailed, and the obſervation which he makes, that "the number of readings is the limit of the number of lines in the Ogum ſcale," will fall to the ground. It may be remarked alſo, that in order to get out the fifth and laſt reading, he is obliged to have recourſe to another unauthorized and arbitrary mode of proceeding: inſtead of decyphering the Ogum line from the broad to the narrow end of the ſtone, he decyphers it from the ſmall to the broad end; but as this, if no other contrivance were alſo uſed, would neceſſarily only give the reading, found out by reverſing the firſt and ſecond readings, he at the ſame time changes the poſition of the ſtone that the proceſſes may be from left to right; ſo that by this mode thoſe cyphers which were properly below the horizontal maſter line, become above it, and *vice verſâ*; and as the letters repreſented by the Ogum cyphers depend upon their poſition above or below this line, he thus gets a new ſet of letters altogether. Certainly, if theſe liberties of tranſpoſing letters were allowed and uſed by Iriſh antiquarians in general, they might make out whatever ſuited their fancy, or hypotheſis from any inſcription or MS.: but who could put faith in their interpretation?

Fifthly. Hitherto the remarks which have been offered go more againſt the interpretation of this inſcription, and againſt its alleged antiquity, than againſt the claim to Druidic origin, maintained for the Ogum cypher, by the Iriſh antiquarian. Another plan which Mr. O'Flanagan deviſed for getting out all the meaning, as he conceived, of this inſcription, will offer us very concluſive arguments on this latter point, at the ſame time that it will ſtill farther prove the arbitrary and unfounded nature of the rules he followed, and the futility of his interpretation.

None of the firſt four readings would be made out if the letters F and N, wherever they occur, were not commuted; but for this commutation no authority is given: it ſeems to have been entirely a thought of Mr. O'Flanagan's, in order to make out ſome meaning from this inſcription, or at leaſt, ſuch a meaning as ſhould prove the monument to be that of Conan; for, be it obſerved, he does not commute them in every caſe, but only "as the ſenſe ſhall direct." Can any thing be conceived more looſe and unſatisfactory than this? It was, indeed, neceſſary that Mr. O'Flanagan ſhould limit the rule he himſelf had laid down; for had the letters F and N been commuted in every inſtance where they occur in this inſcription, the name of Conan would not have been found, either in the firſt or ſecond readings; and as it does not occur in the third, fourth, or fifth readings, the monument might have been that of any other hero, as well as Conan's. So completely does Mr. O'Flanagan follow his rule of commuting the letters F and N, only as the ſenſe ſhall direct, that in the word Conan the firſt *n* is got by retaining that letter, and the ſecond *n*, by commuting the Ogum mark for *f* into that letter.

"This commutability," obſerves Mr. O'Flanagan, "of the letters F and N, depends on a circumſtance peculiar to the Iriſh alphabet, it having two different arrangements; one of which begins with B, L, N, and is called Beithluiſnuin; and the other with B, L, F, and is called Beithluisfearn; the latter is peculiar to the Ogum ſyſtem, but when it is neceſſary for the conſtruction, it does not totally reject the former, which was the alphabet in common uſe, till Greek and Roman literature viſited this country, and made the Iriſh arrange their alphabet, as far as it extended, conformable to their own." This paſſage, though given before, is quoted again, as it ſuggeſts ſeveral moſt important remarks. It is here aſſerted that the Ogum ſyſtem, when it is neceſſary for the conſtruction, does not totally reject the Beithluiſnuin alphabet. But why has Mr. O'Flanagan confined the commutability of the alphabets to the letters F and N? Had the arrangement of the two alphabets agreed in the order of all the letters except theſe, it might have been proper ſo to confine the commutability; but in the order of ſeveral other of the letters, the arrangement is different: but this

circumſtance did not ſuit Mr. O'Flanagan's hypotheſis to mention or apply. It may be added, that had the commutability been carried to its legitimate length (allowing it to be well founded), fifty readings inſtead of five might have been made out of this inſcription.

In the paſſage juſt quoted, Mr. O'Flanagan ſtates a fact which is completely deciſive againſt the Druidic origin and antiquity of the Ogum cypher; this cypher is arranged according to the alphabet called Beithluisfearn, but does not totally reject the alphabet called Beithluiſnuin: now the latter was the alphabet in common uſe until Greek and Roman literature viſited Ireland, when the former alphabet was adopted. It follows, therefore, that the Ogum cypher, having been adapted to an alphabet confeſſedly poſterior in its origin to the introduction of Chriſtianity into Ireland, cannot claim an antiquity greater than that alphabet. Had it been more ancient, it would naturally have been adapted to the more ancient alphabet, though after the introduction of the more modern one, it occaſionally, or, in ſome inſtances, might have been applied to the latter; but as the direct reverſe is the fact, as the Ogum ſyſtem is radically founded on the modern alphabet, while it only does not reject the ancient one, its date muſt be conſidered as contemporary with, at the higheſt, but more probably poſterior to that alphabet, which was introduced into Ireland along with Greek and Roman literature.

The high antiquity, and even the Druidic origin of the Iriſh Ogum, as well as of their alphabet, is contended for on other grounds beſides thoſe which are derived from monumental inſcriptions and old MSS. The Druids, it is aſſerted, had the uſe of letters from the earlieſt period, to which we can trace this order of men; and their letters were formed upon the ſyſtem of ſymbolical ſprigs, which may ſtill be traced in the virgean Ogum, and Beithluiſnuin alphabet of the Iriſh. Of this alphabet, O'Flaherty, in his Ogygea, gives a particular deſcription. "Each letter borrowed its appellation from trees." The book of Lucan, upon whoſe genuineneſs and authority Iriſh antiquaries lay great ſtreſs, though Mr. Aſtle affirms it is only 380 years old, and abounds ſo greatly in fables and abſurdities, that an intelligent reader would as ſoon believe any of the tales related in it, as that the Mileſian colony taught the uſe of letters in Ireland many centuries before the Chriſtian era (p. 121, 122.) gives the following account of the number, order, and name of each letter in the alphabet.

B. 1. *Beithe*, the birch-tree
L. 2. *Luis*, commonly *Caerthean*, the wild aſh.
F. 3. *Fearn*, the alder, of which ſhields are made.
S. 4. *Sail*, the willow.
N. 5. *Nion*, vulgarly *Unſioun*, the aſh-tree of which ſpears are made.
H. 6. *Huath*, vulgarly *See;* white-thorn, or thorny buſhes, that grow on hedges.
D. 7. *Duir*, vulgarly *Cuilcaun*, the ſcarlet oak, broom, holm, or holly.
T. 8. *Tinne.* The explanation of this letter is not given.
C. 9. *Coll*, the hazle.
Q. 10. *Queirt*, vulgarly *Abholl*, the apple-tree.
M. 11. *Muin*, vulgarly *Fineamhuin*, the vine-tree.
G. 12. *Gort*, vulgarly *Fidheaun*, the ivy.
Ng. 13. *Ngedal*, vulgarly *Gilcach*, or *Raid*, the reed.
P. 14. *Pethpec.* There is no explanation of this.
Z. 15. *Ztraif*, vulgarly *Draighean*, the ſloe-tree.
R. 16. *Ruis*, vulgarly *Trom*, the alder-tree.
A. 17. *Ailm*, vulgarly *Gius*, the fir-tree.
O. 18. *Onn*, vulgarly *Aiteann*, furze.
U. 19. *Ur*, vulgarly *Fræch*, heath or ling.
E. 20. *Eadhadh*, vulgarly *Craneriothach*, the aſpen-tree.
I. 21. *Idho*, or *Idhad*, vulgarly *Ibhar*, the yew-tree.
Ea. 22. *Ebhadh*, vulgarly *Criothach*, the aſpen-tree.
Oi. 23. *Oir*, vulgarly *Feords;* the ſpindle-tree, or prick-wood.
Y. 24. *Uillean*, vulgarly *Eadhlean*, woodbine, or honeyſuckle.
Io. 25. *Iphin*, vulgarly *Spirian*, or *Iſpin*, the gooſeberry-tree.
X. 26. *Amhancholl.* The explanation of this letter is not given.

Before proceeding to a direct and formal examination of the Druidic antiquity and origin of this alphabet, one remark may be offered, which, of itſelf, independently of other proof, is ſufficient, in the minds of calm and rational enquirers, to create conſiderable doubts on this point. It will be obſerved that the name of the fourth letter in the Bethluiſnuin alphabet is *ſail*, the willow: he muſt be a ſturdy etymologiſt, indeed, who will contend that this is a primitive Iriſh word, and not a derivative, from the Latin *ſalex*.

But we have a direct and poſitive evidence that the Druids did not make uſe of letters, at leaſt for the purpoſes of religion. Cæſar expreſsly ſays, "neque fas eſſe exiſtimo aut ea litteris mandare; cum in reliquis fere rebus, publicis privatiſque rationibus, *Græcis* literis utantur." The word *Græcis* has by many critics been ſuppoſed to be an interpolation, but it would appear without ſufficient authority. Mr. Aſtle remarks, "that the ancient Gauliſh letters are derived from the Greek, and their writing approaches more nearly to the Gothic than that of the Roman: this appears by the monumental inſcription of Gordian, meſſenger of the Gauls, who ſuffered martyrdom in the third century, with all his family. Theſe ancient Gauliſh characters were generally uſed by that people before the conqueſt of Gaul by Cæſar, but after that period the Roman letters were gradually introduced." (P. 57.) The Roman letters appear to have taken place of the Grecian, or Gauliſh, in Britain about the time of Tiberius; for on a coin of Cunobeline, king of the Caſſii and Trinovantes, who flouriſhed in the reign of that emperor, the letters are decidedly Roman. Now, if the Druids had poſſeſſed an alphabet of their own, it is to be ſuppoſed that it would have been uſed, and not a foreign alphabet on the coins of the Britiſh monarch. When Celſus oppoſed the antiquity and learning of the Druids to thoſe of the Jews, Origen, in reply, denied that there were any writings of the Druids in exiſtence; a denial he would hardly have made had they been as remarkable for their learning and writings, as the Iriſh and other Celtic etymologiſts would have us to ſuppoſe.

Nor are the proofs of the primitive nature and high antiquity of the Iriſh alphabet, drawn from other ſources, better founded. One of theſe proofs is thus ſtated by Mr. O'Halloran, in his "Introduction to the Study of the Hiſtory and Antiquities of Ireland," p. 29. "As a new inſtance of the originality of our characters, we may add that our letters in ancient times were called Feadha, alluding to wood: our Ogum, or hierographic character, is to this day called Ogum croabh, or the branchy type, and every letter in our common alphabet alludes to ſome tree. Our earlieſt writings were on the tablets of birch-tree, called Orauin, and the collected pieces Taibhle-Fileadh, or Philoſophical Tablets. It was to this cuſtom undoubtedly that Horace alluded, when he ſtyled the firſt compoſition of laws, engraving them on wood, leges incidere ligno." It is ſcarcely poſſible to read this proof of the originality of the Iriſh characters,

without a ſmile of credulity and contempt: the very terms uſed to expreſs the collected pieces, are evidently derived from another language, either from the Latin and Greek directly, or from the Engliſh; *Taibhle-Fileadh* bears too cloſe a reſemblance to philoſophical tables, to be regarded as a pure and primitive Iriſh expreſſion. But independently of this circumſtance, what does this pretended proof of the originality of the Iriſh characters amount to? They were engraven on wood, the terms expreſſing them had reference to wood, and therefore they were not borrowed. The reverſe of the inference would have been more rational and probable; for in the primitive ſtate of moſt languages, the ſame was the caſe; and the Anglo-Saxon language, from which there is good reaſon to ſuppoſe the Iriſh borrowed their alphabetical characters, had expreſſions of nearly ſimilar meaning, applied to their alphabet. Indeed in all the northern languages, there is a reference in the word uſed to expreſs an alphabet, to the cuſtom of cutting the letters on wood. In Icelandic, Runa Stafr is an alphabet; and the word Bog-ſtav, or Buch-ſtab, is uſed in Germany to ſignify a letter: this is evidently derived from bog, or buch, a beech-tree, and from ſtav, or ſtab, a ſtaff or ſtick.

But on this point, it is needleſs to add any thing to the opinion and teſtimony of Mr. Aſtle, contained in the following paſſages. "It appears that the Iriſh have neither written monuments nor coins to prove their pretenſions to the uſe of letters, at ſo early a period as they contend for. The tables of wood upon which they are ſaid to have written, no author of any authority ever pretended to have ſeen. But the evidence which we might have expected to have derived from ancient MSS. is defective, indeed; for the oldeſt Iriſh manuſcript which we have diſcovered is the pſalter of Caſhel, written in the latter end of the 10th century." P. 120.

"Mr. Innes, in his "Eſſay on the Antiquities of Scotland and Ireland," and Mr. James Macpherſon, in the third edition of his "Introduction to the Hiſtory of Great Britain and Ireland," produce inconteſtible evidence to invalidate the reports of the Iriſh. Theſe authors contend that Ireland was firſt peopled from Britain; that the former nation was ſo far from being the ſeat of polite learning for many years before the neighbouring nations, or even Greece itſelf had emerged from ignorance, as hath been pretended, that they were generally deemed, by the moſt reſpectable writers of antiquity, to have been leſs civilized than any of their neighbours: that the manners of the old Iriſh were inconſiſtent with the knowledge of letters: that the Ogum was a ſpecies of ſtereography, or writing in cypher; and they thus conclude with deciſive proofs againſt the pretended literature of the ancient Iriſh. They invalidate the accounts of the emigration of the Mileſian colony, and diſpute their pretended extraction from any of the nations of Scandinavia. Great ſtreſs hath been laid, as appears above, by the advocates for the antiquity of letters among the Iriſh, that their alphabet differs from all others in name, order, number, and power. Theſe arguments were adopted by thoſe who contended for the antiquity of the Runic letters, which have been confuted. Mr. Innes, in his eſſay above quoted, p. 446, delivers it as his opinion, that the *Beth*, *Luis*, *Nion*, or alphabet of the Iriſh, was nothing but an invention of the Iriſh ſeanachies, who, after they received the uſe of letters, put the Latin alphabet into a new arbitrary order, and aſſigned to each letter the name of ſome tree; and that this was not a genuine alphabet of the Iriſh in ancient times, or peculiar to them; but was a bare inverſion of the Latin alphabet." P. 122.

"To conclude this head, it is impoſſible to ſay whether all which hath been advanced will operate upon the minds of thoſe of the Iriſh nation, who are ſuperſtitiouſly devoted to the legendary tales of their anceſtors, for it is in vain to oppoſe rational doubts, arguments, or even facts, to popular credulity; although we may with great reaſon ſuppoſe, that the fictions which the vanity and patriotiſm of the Iriſh have been raiſing for ages, will gain no credit with the ſenſible and judicious part of mankind, but will vaniſh before the ſtrong beams of hiſtory and criticiſm: in truth, all ſcepticiſm muſt vaniſh by an inſpection of the 22d plate, wherein we have ocular demonſtration that the Erſe and Iriſh characters are the ſame; and that they are ſimilar to thoſe uſed by the Saxons in Britain, appears from ſeveral Saxon alphabets in the preceding plates; ſo that thoſe who obſtinately perſiſt in aſſerting that the Iriſh characters are not derived from the Roman, after what hath been ſaid on this head, muſt deny the evidence of their ſenſes." P. 138.

But the Iriſh borrowed not only their regular alphabet, but alſo one ſpecies at leaſt of their Ogums: the conſideration of this ſpecies, as more nearly allied to alphabetical characters than the virgular Ogum, we have left to the preſent place; but it will not detain us long. This ſpecies was called the *Marcomannic Runes;* an engraving of them is given by Dr. Ledwich in his "Antiquities of Ireland," p. 329. It might have been ſuppoſed that both the name and the epithet applied to theſe characters, would have ſatisfactorily proved, that the Iriſh had borrowed them from the northern nation: but Mr. O'Halloran contends that the occult manner of writing employed by the northern nations, to which the name *Runic* was given, was not only of Iriſh origin, but that the name *Runic* is purely Iriſh, and cannot be explained in the northern languages. It cannot, indeed, be denied that *run*, in Iriſh, ſignifies ſecreſy, or myſtery; but it has the ſame ſignification in the northern languages. On this point Dr. Ledwich remarks; "The word and its meaning muſt have been adopted from the northern, for it could not co-exiſt in the Teutonic or Gothic, and Celtic, in ſimilar letters and import, unleſs we aſſert theſe tongues to be the ſame. As all know they were not, then we muſt have had it from the northern invaders of this iſle, and to them is to be attributed the loſs of the old Celtic name *Ogum* for that of *Run*, introduced by them. O'Brien, treating of this word, without any deſign of doing ſo, confirms the truth of what is aſſerted, by ſhewing, that in five dialects of the Teutonic, it is preſerved in its original ſignification." P. 332.

The following circumſtance ſtill farther illuſtrates and confirms the idea, that the Iriſh term *run* is derived from the Teutonic dialects, and that from the northern nations, the Iriſh borrowed at leaſt ſome ſpecies of their ſecret characters. The Runes of the northern nations were ſuppoſed, by a particular mode of uſing them, to be poſſeſſed of magical qualities; and the underſtanding and application of theſe qualities were confined to the prieſts and prieſteſſes: of the latter, Keyſler gives a very full and curious account (Antiquitates Septentrionales, p. 371.), and informs us that they were called *Alirunee;* but according to O'Brien (Iriſh Dictionary, *in voce*) *Alarunaighe*, in the Iriſh language, is the wiſe man acquainted with ſecrets. The Marcomannic Runes, therefore, employed by the Iriſh, as well as the term *run*, may fairly be conſidered as of Teutonic origin.

The following are the general concluſions which may be drawn from the authorities and arguments brought forward in this article.

1. That the virgular Ogum cannot have an origin prior to the introduction of Greek and Roman literature into Ireland, ſince it is adapted to an alphabet, the arrangement of which took place at that time.

2. That

2. That the Iriſh alphabets bear ſtrong marks of having been borrowed from the Anglo-Saxon inhabitants of England. The alphabet called Bobeloth is regarded as the oldeſt, and Dr. Ledwich remarks, that "the names and figures of the letters are exactly in the ſtyle of the Britiſh, Runic, and Marcomannic runes," and this, the plate he has given of it ſufficiently proves: the form of the letters in the Bethluiſnuin alphabet is ſtill more palpably derivative and modern.

3. That the Iriſh claim to literature, in very early periods of their hiſtory, and eſpecially their claim to Druidic literature, is utterly unfounded.

With reſpect to the mode of aſcertaining the comparative antiquity of MS., written in the virgular Ogum, Mr. Aſtle informs us that "Diphthongs are not found in the ancient MSS.: the vowels are written ſeparately, as *a e*, not *æ*, &c. therefore an Ogham or cypher with marks for diphthongs is not ancient." (P. 189.) Mr. Aſtle adds, that king Charles I. correſponded with the earl of Glamorgan, when in Ireland, in the Ogham cypher, a ſpecimen of which he gives in his thirty-firſt plate. Some of this coreſpondence is preſerved among the royal letters in the Harleian library.

Iriſh etymology is ſuch delicate ground to tread upon, and it offers, in general, ſo little that is ſatisfactory, or uſeful, that we ſhould conclude this article without examining into the derivation of the word *Ogum*, did it not throw light, as we conceive, on a curious, and little underſtood paſſage in one of Lucian's dialogues.

It is rather ſurpriſing that ſuch an undaunted and ſanguine Iriſh antiquarian and etymologiſt as colonel Vallancey ſhould aſſert (Iriſh Grammar, p. 4.), "that authors are at a loſs for the derivation of the word Ogum, which is not to be found in any dictionary of the Iriſh." That it is not to be found in them is very true; and (as has been already remarked) as the word *Run*, even in the oldeſt MSS., is uſed to ſignify ſecret writing, and not the word *Ogum*, this is a proof that, even in very remote times, the mode and practice of this kind of writing was borrowed by the Iriſh from the northern nations. But though the word *Ogum* is not to be found in Iriſh dictionaries, it exiſted in the old Celtic: it ſtill exiſts in the kindred dialect of the Welſh; and in both theſe languages its meaning is certain, and appropriate to its application at preſent in the Iriſh language. Keyſler (Antiq. Septen. p. 38.) expreſsly ſtates, "probe noverim, vocabulum *Oga*, Ogum, vel Ogma Celte ſignificaſſe ſecreta literarum, vel literas ipſas." And Rowland, in his Mona Antiqua, p. 238, ſays, it is ſtill preſerved in the Welſh.

But Mr. O'Flanagan (Iriſh Tranſactions, p. 13.) traces its origin and meaning ſtill farther back in the Iriſh language. The fundamental rules of the Ogum are given in five circles, drawn at certain intervals within each other; a diagram of which, taken from the Book of Ballymotte, he gives in page 16. Hence he derives the word Ogum from Oc, Ogh, or Ogha, a circle; and he adds, "as the lines of which it is compoſed evidently refer to an alphabet already exiſting, by this word (Ogum) in our language is underſtood an obſcure character, or an occult manner of writing."

Without laying much ſtreſs on this attempt to trace the word *Ogum* ſtill farther back in the Iriſh language, it ſeems evident that it is a Celtic term, which formerly exiſted in this language, though now loſt, except in its application to the cyphers which go under that name. O'Halloran, however, in his zeal to prove this point, goes even beyond the common degree of Iriſh etymological ignorance or raſhneſs, in the following paſſage, in his Introduction to the Study of the Hiſtory and Antiquities of Ireland, p. 38. "We have a recent evidence that the word came from Ireland; for William Halloran, head of the nominals at Orford, the contemporary and great opponent of our Scotus, is better known amongſt ſchoolmen by the name of William of Ocham, and Ogham, than by his real name of O'Halloran; the name of Ogham being given him by his countrymen, on account of his great knowledge in this occult writing, and in which, Ware declares, he was poſſeſſed of an entire book wrote in vellum." It is ſcarcely poſſible to produce from any author ſo ſhort a paſſage, containing ſo much ignorance and miſrepreſentation. From the conſtruction of the latter part of it, one would ſuppoſe that we had Ware's authority, that William Halloran poſſeſſed an entire book of Ogums; whereas the real meaning is, that Ware poſſeſſed ſuch a book. Beſides, William Halloran was never called William of *Ogham;* and the epithet of Ocham, or Okeham, applied to this philoſopher, might have led Mr. O'Halloran to ſuſpect that this was the name of his birth-place, even had he been ignorant that he was actually born at Okeham in Surrey, and took his appellation, as was uſual, from that place. But the honour of his country, and his fondneſs for Iriſh etymology and antiquity, eſpecially when aided by an opportunity of celebrating a nameſake, and probably an anceſtor of his own, ſeems to have been too ſtrong for Mr. O'Halloran's love of hiſtoric accuracy.

Though colonel Vallancey confeſſes himſelf ignorant of the Iriſh derivation of the word *Ogum*, yet, in conformity to his known ſyſtem of Iriſh antiquities, he finds no difficulty in tracing it back to an oriental origin. It is derived, according to him, from the Chaldaic or Phœnician אֹרֶם, *Ocham:* and though there is much doubt among the rabbis reſpecting the meaning of this term; ſome explaining it to mean a cheſt to keep ſecret writing in; others, brazen veſſels; while others think it is the name of the town; colonel Vallancey poſitively avers, but without vouchſafing to give reaſon or authority for his aſſertion, that "the true and literal meaning of the word is a *court character*, appropriated to the records of the church and ſtate." Archæologia, vii. 284.

But though colonel Vallancey can bring forward only his own aſſertion for the oriental origin and meaning of the word *Ogum*, there can be little doubt that this, or a very ſimilar word, exiſts in the eaſtern language, with exactly the ſame meaning as it poſſeſſes in Iriſh. Mr. Weſton, in a paper in the 14th volume of the Archæologia, p. 246, quotes the authority of ſir William Jones, to prove that, in the Sanſcrit, the word *agam* means myſterious; and is derived from *gama*, to go, with the *a* prefixed, ſignifying to go to, to come at, or to acquire the knowledge of.

To apply the remarks which have been offered, reſpecting the etymology and meaning of the word *Ogum*, to the paſſage of Lucian, already referred to. Lucian, in his piece, entitled "De Hercule Gallico," edit. Paris, 1615, p. 853, deſcribes the Celtic Hercules; but from his account of him, it is evident that the Gauls viewed and worſhipped Hercules exactly in the ſame light as the Greeks and Romans did Mercury, *viz.* as the god of eloquence. This, indeed, he ſays, he was expreſsly informed by a Celt. But "the Celts," adds Lucian, "call Hercules by a word in their own vernacular tongue, *Ogmian*" (ογμιος). Schmidt, in a diſſertation in the firſt volume of the Archæologia, endeavours to prove that ογμιος had the ſame meaning in Celtic as in Greek, and is properly a furrow or boundary. For this he is rudely attacked by Toup, who conſiders ογμιος as a corruption for ομογνιος, and that the Hercules of Lucian is ομογενιος, or one of the dii penates.

As, however, Lucian expreſsly ſays that ογμιος was a Celtic word, we muſt look for its meaning in the dialects of that

that language; and as it was applied by the ancient Celts to their god of eloquence, the meaning, in all probability, has reference to the character of this deity. But the word *Ogum* is ſo ſimilar to it, both in ſound and meaning, that little doubt can be entertained that "*Hercules Ogmius* (to uſe the words of Keyſler) non alius ſit, quam *literatus, doctus, eloquens.*" So far this part of Lucian's writing may be rationally and ſatisfactorily explained; but the opinion of Campbell and Toland, that, in the deſcription which Lucian gives of the Celtic Hercules, the nature and properties, as well as the name of the Iriſh alphabet, may be diſcovered, is too wild and ridiculous to claim a moment's inveſtigation or notice

OGHAO, in *Geography*, a ſmall iſland in the South Pacific ocean, weſt of Annamooka.

OGIDOO, a town of Bengal; 24 miles S.W. of Ramgur.

OGIER, Charles, in *Biography*, a man of learning, was born at Paris in 1595. He ſtudied firſt at Bourges, afterwards at his native city, and then went to Valence to attend lectures in the law, of which faculty he was made a doctor. He followed for ſome time the profeſſion of an advocate; but becoming diſguſted with this employment, he accepted the poſt of ſecretary to Claude de Meſmes, count d'Avaux, in his embaſſy to the northern courts. Ogier accompanied him during his miſſion in the years 1634 and 1635, and drew up an account of his travels; when the count d'Avaux, finding himſelf complimented in it, deſired him to keep it in MS. for 20 years. It was firſt publiſhed in 1656, under the title of "Caroli Ogerii Ephemerides ſive Iter Danicum, Suecicum, Polonicum, cum eſſet in Comitatu illuſtro Claudii Memmii, Comitis Avauxii, ad ſeptentriones Reges extraordinarii Legati." This work contains many curious particulars of the manners and cuſtoms, the eminent characters, &c. of the countries viſited by the author, and likewiſe of the negociations of the count d'Avaux. It is interſperſed with Latin verſes. Ogier died in 1654. He had a brother Francis, an eccleſiaſtic, who attended the count d'Avaux, when he went to ſign the peace of 1648. He was author of poems, ſermons, and other works, of which one of the moſt eſteemed was his "Jugement et Cenſure de la Doctrine curieuſe de Fr. Garaſſe." He died in 1670. Moreri.

OGILBY, John, who had a conſiderable ſhare in introducing typographical ſplendour into this country, was born in the year 1600, at or in the vicinity of Edinburgh. His father, who was a branch of an ancient and conſiderable family, became a priſoner for debt in the king's bench, and was unable to give his ſon a liberal education: he, therefore, bound himſelf an apprentice to a dancing-maſter in London, and was afterwards employed in the family of the earl of Strafford, who appointed him deputy-maſter of the revels at Dublin, where Ogilby erected a theatre. To his honour it is mentioned, that with the firſt money which he earned, he freed his parent from priſon; an act of filial piety deſerving of the higheſt commendation. By a ſevere ſtrain in the muſcles of his leg, he was obliged to procure ſome other means for obtaining a livelihood. "It is not worth while," ſays his biographer, "to purſue the various fortunes of his life, through which he diſplayed extraordinary induſtry, a projecting head, with a talent of obtaining patronage in the execution of his projects, and a ſpirit not to be depreſſed by misfortunes and reverſes." He overcame his want of a literary education, ſo far as to be able to tranſlate from the Latin and the Greek: hence we have his verſions of Homer and Virgil. His Homer, though a very bad tranſlation, had the honour of being a great favourite with Pope in his childhood, and is thought to have kindled the poetical flame in his breaſt. The cuts to his tranſlation of Virgil were highly valued, and ſerved for a ſplendid edition of that poet. He publiſhed a magnificent edition of the bible with plates, for which he was remunerated by the houſe of lords. In 1661 he was appointed to conduct the ceremonies at the king's coronation, of which he publiſhed a pompous account in folio, with plates. He had the misfortune to loſe his whole property in the great fire of London; after which he obtained the appointment of his majeſty's coſmographer and geographic printer, in which capacity he printed ſome volumes of his great Atlas. He alſo publiſhed an account of Japan; and an account of the great croſs-roads of the kingdom, from his own actual ſurvey and menſuration by the wheel, which was for a conſiderable time a ſtandard work, and paſſed through many editions. He died in 1676.

OGIVES, or Og *Arches*, in *Architecture*, are arches or branches of a Gothic vault, which, in lieu of being circular, paſs diagonally from one angle to another, and form a croſs with the other arches which make the ſide of the ſquares, whereof the ogives are diagonals.

The middle, where the ogives cut or croſs each other, is called the *key*, which is ſometimes carved in form of a roſe, or a cul de lampe. The members or mouldings of the ogives are called nerves, branches, or reins; and the arches which ſeparate the ogives, double arches.

OGLETHORPE, James, in *Biography*, an Engliſh general, born in Weſtminſter about the year 1688, was the ſon of ſir Theophilus Oglethorpe of Godalmin in Surrey, who was accuſed of diſaffection in the reign of William and Mary. He entered the army as an enſign in 1710. He afterwards ſerved under prince Eugene, to whom he became ſecretary and aid-de-camp. On the reſtoration of peace, he returned home, and obtained a ſeat in the houſe of commons, where he was diſtinguiſhed by his exertions for the benefit of trade, and a reform in the priſons. In 1732 he went to America, ſettled in Georgia, and erected the town of Savannah. He again viſited that country, and made an unſucceſsful attempt upon Fort Auguſtine, the capital of Florida, belonging to the Spaniards. For this he was tried, on his return to England, and acquitted. In 1745 he was promoted to the rank of major-general, and was ſent againſt the rebels, but did not overtake them; on which account, the buſineſs was inveſtigated by a court-martial, but the general was honourably acquitted. He died in 1785, at the advanced age of 97, being by many years the oldeſt general in his majeſty's ſervice. Smollet's Continuation, vol. i. and ii. European Mag.

Oglethorpe, in *Geography*, a county of Georgia, in America, on the north ſide of Alatamaha river, weſt of Liberty county; containing 9780 inhabitants, of whom 3089 are ſlaves.

OGLIASTRO, a town of the iſland of Sicily, in the valley of Mazara; 9 miles S.S.E. of Palermo.

OGLIO, a river of Italy, which riſes in the biſhopric of Trent, and joins the Po at Bergo Forte.

Oglio. See Olio.

OGMO, in *Geography*, a town of Lower Siam, on the eaſt ſide of the gulf. N. lat. 13° 43′. E. long. 101° 48′.

OGMU, a town on the weſt coaſt of the iſland of Leyta. N. lat. 10° 55′. E. long. 124° 30′.

OGNATA, a town of Spain, in Guipuſcoa; 3 miles S.W. of Segura.

OGNI, a cluſter of five ſmall iſlands in the Grecian Archipelago, between the iſland of Scio and the coaſt of Natolia. N. lat. 38° 33′. E. long. 26° 14′.

OGOA,

OGOA, in *Mythology*, a deity worſhipped by the Carians, eſpecially in the city Mylaſſus. We learn from Pauſanias (In Arc.), that the ſea, which was thought to paſs under the temple of this god, ſometimes overflowed it. It is probable, therefore, that Ogoa was the name which the Mylaſſians gave to the god of the ſea.

OGOLETZ, in *Geography*, an iſland of Ruſſia, in the ſtraits of Vaigatſkoi. N. lat. 69° 40′. E. long. 26° 14′.

OGOR, a river of Ruſſia, which runs into the Duna, 12 miles S.E. of Riga.

OGOROO, one of the ſmaller Friendly iſlands; 15 miles N. of Annamooka.

OGOST, a river of European Turkey, which runs into the Danube near Rakova, in Bulgaria.

OGOUA. See OEGWA.

OGRAM LOUGH, a lake of the county of Clare, Ireland, the river flowing from which paſſes through Scarriff to the Shannon. By Dutton and Pelham it is called Lough O'Grady. It is in the north-eaſtern mountainous diſtrict of the county. Beaufort.

OGRAN, a town of Hungary; 15 miles N.N.W. of Preſburg.

OGRESSES, or AGRESSES, in *Heraldry*. See PELLETS.

OGULIN, in *Geography*, a town of Croatia; 32 miles E. of Fiume.

OGYGES, in the *Hiſtory of the Heroic or Fabulous Age* of Greece, a ſovereign of Attica and Bœotia, under whoſe reign happened the inundation ſince known by the name of Ogyges's deluge. Whether this prince was a native or a foreigner; at what time he lived; and what was the deluge which happened under his reign, are queſtions of no very eaſy ſolution. The Greek hiſtorians tell us, that Ogyges reigned, as we have ſaid, in Attica and Bœotia, while Phoroneus, the ſon of Inachus, governed Argolis, and that it was in his time the deluge happened which has paſſed under his name, and the date of which Cenſorinus fixes about the year 1200 before the Trojan war: but in proof of theſe facts they cite no authorities. The Parian Marbles ſay nothing of it, and that famous chronicle begins only with the arrival of Cecrops in Greece. According to Auguſtine (De Civ. Dei), the deluge of Ogyges happened under Phoroneus, the ſecond king of Argos; and he alleges, that this was the opinion of Euſebius and Jerome. Sir Iſaac Newton, who has very much contracted the antiquities of Greece, places the date of this deluge in the year 1045 before our vulgar era. Julius Africanus, on authorities which he has cited, and among others that of Diodorus Siculus, maintains, that Ogyges lived more than 1020 years before the firſt Olympiad, and conſequently nearly 1800 years B.C.; and this date agrees with the opinion of Petavius, who fixes the deluge under that prince's reign to the year 1796 before our vulgar era. St. Jerome contends, that it was not at Attica, as all the ancients allege, but in Egypt that the deluge of Ogyges happened; but as Jerome ſuppoſes that prince to have been contemporary with Moſes, we may conjecture that this contended deluge was nothing elſe but the event that happened in the Red ſea at the exodus of the Hebrews. Banier thinks it certain, that Ogyges was not a native of Greece; but does not determine whether he was from Egypt or Phœnicia, or from the country of Amalek. He went and ſettled at Thebes in Bœotia, named frequently by the ancients Ogygian Thebes; and he reigned alſo over Attica. It was under his reign the inundation happened, which occaſioned great deſolation in the country, and went by the name of the deluge. The epocha of the deluge is placed by Banier towards the year 1796 B.C., agreeably to the Greek hiſtory, and to the opinion of Petavius and Marſham. In Blair's Table, the reign of Ogyges in Attica is fixed in the year 1796 B.C., and his death in 1764 B.C., when the deluge happened; which deluge is ſaid to have laid waſte the country of Attica for 200 years, till the coming of Cecrops.

OGYGIÆ INSULÆ, or *Ogygian Iſles*, in *Ancient Geography*, comprehend a certain number of iſlands near that part of Italy called Brutium, to the eaſt, and oppoſite to a kind of peninſula, north-eaſt of the Scylacian gulf. They are repreſented as the territory of the nymph Calypſo, and one of them bears her name, as well as that of Ogygia. It is particularly deſcribed by Pliny.

OHAMANENO, in *Geography*, a ſmall but good harbour, on the weſt ſide of Ulietea, one of the Society iſlands. The channel leading into it is about a quarter of a mile wide, lying between two low ſandy iſlands, within which is good anchorage in 28 fathoms, and ſoft ground. S. lat. 16° 45′. W. long. 151° 38′.

OHAMENE HARBOUR, a fine bay on the eaſt ſide of Otaha, one of the Society iſlands; which paſſes in between two ſmall iſlands, Tochoutu and Whannuaia, forming a good harbour, with 25 to 26 fathoms water.

OHANG JAVA, a group of nine iſlands in the Pacific ocean, diſcovered by Taſman, and lying in S. lat. 4° 36′. E. long. 154° 17′. One of theſe iſlands is of conſiderable extent, the other eight are ſcarcely better than large rocks; but though they are low and flat, they are well covered with wood, and abound with inhabitants. The people are black, and woolly-headed, like the Negroes of Africa. Their weapons are bows and arrows; and they have large canoes, which they navigate with a ſail.

OHATOOA, one of the Navigator's iſlands, probably the ſame with that called by La Perouſe *Ozolova*; which ſee.

OHERURUA, a harbour on the weſt coaſt of the iſland of Otaha. S. lat. 16° 38′. W. long. 151° 30′.

OHETEROA, an iſland in the South Pacific ocean, 13 miles in circuit, and rather high than low, but neither populous nor fertile in proportion to the other iſlands in theſe ſeas. The chief produce ſeemed to be the tree of which they make their weapons, called in their language "Etoa." It was encompaſſed by Cook and his companions, Auguſt 1769; but it had neither harbour nor anchorage about it. The natives, who were fierce and hoſtile, ſeemed to be luſty and well made: under their arm-pits they had black marks about as broad as the hand; they had alſo circles of the ſame colour, but leſs broad, round their arms and legs, but no other part of the body was marked. The cloth that formed their dreſs reſembled that of the other iſlands in its materials, of a bright but deep yellow, covered with a compoſition like varniſh, which was either red or of a dark lead colour: over this were painted ſtripes of many different patterns, regularly diſpoſed. Their habit was a ſhort jacket of this cloth, reaching about as low as their knees, conſiſting of one piece, and ſtitched round with long ſtitches. It was girt round them in ſuch a manner, that they exhibited a gay and warlike appearance. Some had caps of the feathers of the tropic-bird, and ſome had cloth turbans. Their arms were long lances, made of the hard wood of the tree called Etoa, well poliſhed and ſharpened at one end, ſome of which were 20 feet long, and three fingers thick. They had alſo a weapon, which was both a club and pike, and made of the ſame wood, about ſeven feet long, and poliſhed and ſharpened at one end with a broad point. As a guard, when they attacked each other, they had ſeveral folds of mats, placed under their clothes from the

the neck to the waiſt. Other things which were ſeen in this iſland were ſuperior to any which our navigators had ſeen before: the cloth was better dyed, and painted with greater neatneſs and taſte; the clubs were better cut and poliſhed; and the canoe, though ſmall, was very richly ornamented and well carved. Their hoſtile diſpoſition prevented any intercourſe. Hawkeſworth's Voyages, vol. ii. p. 273, &c.

OHETUNA, a harbour on the ſouth-eaſt coaſt of Ulietea.

OHEVAHOU, an iſland in the South Pacific ocean. S. lat. 9° 42′. W. long. 139° 2′.

OHHUD, a mountain of Arabia, in the province of Hedsjas, where Mahomet was defended by the Koreiſh; 8 miles N. of Medina.

OHIO, one of the United States of America, admitted into the union by act of congreſs, April 28th 1802, and organized March 3d 1803. Its length and breadth are 200 miles each; and it lies between 38° 10′ and 40° N. lat., and 80° 30′ and 85° 45′ W. long. Excluſively of the waters of lake Erie and Sanduſky, it contains 39,128 ſquare miles nearly, or 25,043,637 acres; of which 17,409,717 acres have been purchaſed of the Indians. Of theſe lands, to which the Indian title is extinguiſhed, 580,159 acres have been appropriated for the endowment and ſupport of an univerſity, an academy, and ſchools, and for the ſupport of religion; 8,418,068 acres are private property; and the remaining 8,411,490 acres are reſerved for the future diſpoſal of congreſs. This ſtate lies weſt of Pennſylvania, and is bounded ſouth by the Ohio river; weſt by the Indiana territory, being ſeparated from it by a line drawn from the mouth of the Great Miami river due north, nearly to the parallel of 42° N. lat.; north by Michigan territory and lake Erie, from the former of which it is divided by an eaſt and weſt line drawn through the ſoutherly extremity of lake Michigan, and interſecting the territorial line in lake Erie; eaſt by Pennſylvania. In 1804, this ſtate was divided into 18 counties, as in the following table:

Counties.	When conſtituted.	No. white Males of 21 Years and upwards, according to the Cenſus of 1803.	Chief Towns.
Trumbull	1799	1111	Warren
Columbiana	1803	542	
Jefferſon		1533	Steubenville
Bellmont	1803	1030	Pultney
Waſhington	1788	1246	Marietta
Gallia	1803	307	Galliopolis
Scioto	1803	249	Alexandria
Adams		906	Maſſieſburgh
Clermont		755	Williamſburgh
Hamilton	1799	1700	Cincinnati
Muſkingum	1803	†	
Fairfield		1051	New-Lancaſter
Roſs		1982	Chilicothe
Franklin		240	Franklington
Warren		854	
Greene		446	
Butler		836	
Montgomery		526	
		15,314	

† Included in Waſhington county.

The whole number of inhabitants in Ohio in 1803, was eſtimated at about 76,000, excluſively of ſeveral hundreds of people of colour, and the conſtant influx of emigrants amounting yearly to about 12,000.

For judicial purpoſes, the ſtate of Ohio is divided into three circuits, *viz.* 1. Butler, Clermont, Greene, Hamilton, Montgomery, and Warren. 2. Adams, Fairfield, Franklin, Gallia, Roſs, and Scioto. 3. Bellmont, Columbiana, Jefferſon, Trumbull, and Waſhington.

The chief towns of this ſtate are Marietta, Chillikothe, Cincinnati, Galliopolis, Xenia, &c. which ſee reſpectively. The principal rivers are the Ohio, Muſkingum, Hockhocking, Scioto, Miami, &c. Although a great part of this country is uneven, it cannot be called mountainous nor even hilly. However, in the upper and northern parts of the ſtate it may deſerve the latter appellation, and it is too rough to admit of much cultivation; and in other parts the inundation and ſettlement of the waters render it waſte land. No part of the federal territory unites, as it is ſaid, more advantages, with regard to health, fertility, variety of productions, and foreign intercourſe, than that tract which ſtretches from the Muſkingum to the Scioto and the Great Miami rivers. The country on the Ohio is every where pleaſant, with large level ſpots of rich land, and remarkably healthy. The bottom and ſides of the river are ſtony from Pittſburg down to the low country, a diſtance of about 800 miles. The ſtrata of ſtone are horizontally diſpoſed, and conſiſts principally of either free-ſtone or lime-ſtone. Although the flat lands on the Ohio are not ſurpaſſed by any in the United States for fertility, they are in many places ſmall and inconſiderable, being encircled by hills and mountains on one ſide and the river on the other. The lands on the various ſtreams that fall into the Ohio are interſperſed with all the variety of ſoil which conduces to pleaſantneſs of ſituation, and lays the foundation for the wealth of agricultural and manufacturing people. Large level bottoms, or natural meadows, (*priaries*) from 20 to 50 miles in circuit, are every where found bordering the rivers and variegating the country in the interior parts. Theſe afford a peculiarly rich ſoil, and may be cultivated with little labour. In many of theſe bottoms a man may clear an acre a day, fit for planting with Indian corn; as here is no underwood, and the trees, which grow high and large, are not thickly ſet. This country produces all the neceſſaries of life in great abundance, and far beyond the conſumption of the inhabitants; the reſidue, with many other articles, ſuch as hemp, cordage, hard-ware, glaſs, whiſkey, apples, cider, and ſalted proviſions, are carried down the river to New Orleans, where they find a ready market. Iron, lead, and copper are found in ſeveral places: beſides native ſulphur, nitre, and alſo vitriol and alum. Every part of the ſtate ſupplies pit-coal (lithanthrax); and the mines of it are not only abundant, but inexhauſtible, from Pittſburgh many miles down the river. Boles and pigments are found on the banks of the rivers: clay ſuitable for pottery and bricks is abundant. On the banks of the Ohio are fine marcaſites, ſometimes called thunder-ſtones; theſe are black, leſs ponderous than coal, and yet capable of giving fire when ſtruck againſt ſteel. Their compoſition is irregularly foliaceous; in the fire they yield a blue ſulphurous flame, and calcine into a purple powder. The natives uſe them in curing or rather bleaching leather. The prevailing growth of timber and the more uſeful trees are maple and ſugar-tree, ſycamore, black and white mulbery, ſome of which are of a very large ſize, black and white walnut, cheſnut, various ſorts of oak, hickory, cherry, buck-wood, or horſe cheſnut, honey-locuſt, elm, cucumber-tree, lynn-tree, gum-tree, iron wood, aſh,

aſh, aſpin, ſaſſafras, crab-apple tree, papaw or cuſtard apple, a variety of plum trees, nine bark-ſpice, and leather wood buſhes. Both the high and low lands produce great quantities of various kinds of grapes, from which the ſettlers ſupply their own conſumption with rich red wine. Hops grow ſpontaneouſly. The ſugar maple is the moſt valuable tree for an inland country. One tree will yield on an average about four pounds of ſugar a year, and the labour is trifling. The ſap is extracted in the months of February and March, and granulated, by the ſimple operation of boiling, to a ſugar equal in flavour and whiteneſs to the beſt Muſcovado. Springs of excellent water abound in every part of the territory; and ſmall as well as large ſtreams for mills and other purpoſes are interſperſed; but as there is little fall in the ſtreams, they fail in dry ſeaſons, and good mill-ſeats are ſcarce. The ſwamps may be eaſily drained and converted into arable and meadow land; and the hills, though frequent, are gentle and ſwelling; the ſoil is deep and rich, covered with a heavy growth of timber, no where incapable of tillage, and well adapted to the production of wheat, rye, indigo, tobacco, &c. In this ſtate, the orchard and garden fruit-trees thrive ſurpriſingly; the peach trees bear abundantly, and the fruit is ſuperior in ſize, beauty, and flavour to any that is raiſed in the northern ſtates. The productions of the fields, in general, are wheat, oats, barley, rye, Indian corn, hemp, flax, and cotton. The gardens yield all the culinary plants in perfection. Melons grow to a large ſize, and ripen into deliciouſneſs. Over the ſurface of the ground and in the extended foreſts grows a natural herbage, in great abundance, on which cattle are found to thrive remarkably well. This country alſo affords ample gratification to the curious botaniſt in his reſearches for new, rare, and curious plants. The climate in this ſtate is exceedingly mild and agreeable. The winter commences at the ſolſtice and laſts about two months. The ſnow does not lie upon the ground for more than three days. It ſeldom freezes for more than five or ſix days ſucceſſively, at which time the ſurface of the ſtagnant waters and of the ſmaller ſtreams is congealed. The winds in winter are very variable; and the ſevereſt cold attends the N.W. wind. In January are many fine days, a pure ſerene air, and clear ſun-ſhine, with ſoutherly and ſouth-weſterly winds. The ſpring is attended with rains and cloudy weather, with ſouth and ſoutherly winds. In the latter end of April the ſeaſon is in its flowery prime. During the ſummer the heats increaſe, tempered at night by refreſhing breezes up the river. There are frequent ſhowers with thunder. The autumn is diſtinguiſhed by ſerene and fine weather: but at the autumnal equinox the rains begin, with cold winds from the N.E. round to the N.W. The ſalubrity of the climate is equal to that of any part of the United States; though on ſome of the low and wet grounds fever and ague are prevalent. The diſtance of 100 miles N. or S. makes a great difference in the temperature of the air. Near the river Sanduſky the cold is much more ſevere, with a greater quantity of ſnow, than on the Muſkingum; and on the Scioto ſnow hardly ever remains on the ground. The weather alſo varies conſiderably on the E. and W. ſide of the Alleghany mountains. All ſtorms of thunder and lightning riſe either with S.W. or N.W. winds; but in Pennſylvania the N.W. wind brings fine and clear weather.

The exports from this country conſiſt of flour, corn, hemp, flax, cotton, beef, pork, ſmoked hams, veniſon, whiſkey, peach-brandy, oak-ſtaves, lumber, &c. raw and tanned hides, and peltry. Ship building has lately commenced and is likely to increaſe with advantage to the country.

No country was originally better ſtocked with wild game of every kind than this. Innumerable herds of deer and wild cattle were ſheltered in the groves, and fed in the extenſive low grounds that abound here. Turkies, geeſe, ducks, ſwans, teal, pheaſants, partridges, &c. were within a few years paſt very plentiful; but on the approach of ſettlers, buffaloes diſappear. Geeſe and ſwans are now ſeldom killed; ducks are not plentiful. Bears, deer, and turkies, are now the principal game. At the falls of the Ohio, geeſe and ſwans are found in great plenty. The rivers abound with various kinds of fiſh, which are generally large and of excellent quality.

Among the curious antiquities of this country we may mention its forts, which are moſtly of an oblong form, ſituated on well choſen ground, and contiguous to water. They are very ancient, and it is ſuppoſed that they were conſtructed 1000 years ago, but for what purpoſe and by whom, are queſtions of ſpeculation and reſearch. At a convenient diſtance from theſe are tumuli or mounds of earth, ſomewhat reſembling the barrows of other countries (ſee BARROW); and which have been found to contain a chalky ſubſtance, ſuppoſed to be bones and of the human kind. Other works have been diſcovered 90 miles from Marietta, on one of the weſtern branches of the Muſkingum, extending near two miles, the ramparts of which are now in ſome places more than 18 feet in perpendicular height. Theſe elevated mounds, ſquares, and forts, reſemble thoſe of Mexico, and it has been ſuggeſted that they have the ſame original; and they have been aſcribed to a people, the moſt ancient of which there is any account in that part of the world, called by Clavigero, in his "Hiſtory of Mexico," Toltecas. He deſcribes theſe people as celebrated for their ſuperior civilization and ſkill in aſtronomy and the arts. Theſe people are ſaid to have been baniſhed from their native country, and to have commenced an emigration about the middle of the ſixth century. In the courſe of their emigration they ſtaid for different intervals of time in various ſtages of their journey; in ſome places erecting houſes and directing their attention to the concerns of agriculture. The fact of ſuch an emigration from a northern region of theſe brave and warlike people, at an early period, though it is not poſſible accurately to aſcertain the dates of every event, cannot be doubted: and that they erected the fortifications and mounds that are here mentioned, as they advanced in their progreſs, ſeems not improbable. It merits conſideration alſo, that the ſituation, conſtruction, form, and general contents of the Aſiatic tumuli and the ancient American mounds are ſo ſimilar, that they may be aſcribed to the ſame people. Many other reaſons may be ſuggeſted to juſtify the opinion that the aborigines of America were deſcendants of the ancient Scythians, and paſſed into that continent from the eaſtern parts of Aſia; ſuch is the practice of ſcalping their priſoners, the fabric and ſtructure of birch canoes, the method of marching in what is called "Indian file," and the conſtruction of implements of war and inſtruments of the chaſe. Many other circumſtances might be mentioned, in which there is a reſemblance between the ancient Americans and the Tartar tribes of Aſia.

Other curioſities of this country, are the caves of artificial conſtruction found on the bank of the Ohio: in one of which, called by the Indians "the habitation of the great ſpirit," are found inſcriptions, names of perſons, dates, &c. Among the natural curioſities of this country we might alſo mention the "Prairiés," which are immenſe plains of different ſorts, occaſioned either by the exſiccation of lakes or vaſt moraſſes, or by the abſorption of the rains that fall upon them, and which reſemble the vaſt "Steppes" in the upper

parts of Ruſſia and Siberia. There are alſo found open cleared ſpots on the ſummits of hills, called "Buffaloe beats," becauſe they are ſuppoſed to have been occaſioned by the reſort of theſe animals thither in fly time. The "ſalt licks" are alſo among the natural curioſities of this country.

For a more particular account of theſe remains of antiquity we refer to Harris, ubi infra. At Athens, in the diſtrict of Middletown, is the "Ohio Univerſity," eſtabliſhed by an act paſſed on the 12th of December, 1801. This inſtitution, though recently eſtabliſhed, is endowed with 46,000 acres of land, within which the town of Athens, on the Hockhocking river, 40 miles by water from the Ohio, is pleaſantly ſituated. Of this land, 1500 acres were cleared in 1804, leaſed, and inhabited by 100 families. The corporation conſiſts of the governor of the ſtate for the time being, the preſident, and not more than 15, nor leſs than 10 truſtees.

The legiſlative authority of this ſtate is veſted in a general aſſembly, compoſed of a ſenate to be choſen biennially, and a houſe of repreſentatives to be choſen annually, both by the people: the repreſentatives to be proportioned by law from time to time to the population. The ſenators are divided into two claſſes, by lot; the ſeats of the firſt claſs to be vacated at the expiration of one year; of the ſecond at the expiration of the ſecond year; ſo that one-half is to be annually choſen. The houſe of repreſentatives have the power of impeachments, which are to be tried by the ſenate. The ſupreme executive power is veſted in a governor to be choſen biennially, by the people: he is eligible only ſix years in any term of eight years. The judiciary power is veſted in a ſupreme court, in courts of common pleas in each county, and juſtices of the peace. The judges of the ſupreme and county courts are to be appointed by a joint ballot of the two houſes of aſſembly, to hold their offices for ſeven years. In all elections, all white males, above the age of 21 years, having reſided in the ſtate one year next preceding the election, and who have paid or are charged with a ſtate or county tax, ſhall enjoy the right of an elector, in the diſtrict where he actually reſides at the time of the election.

The ſettlement of this county was checked and retarded for ſeveral years by the Indian war, which terminated on the 3d of Auguſt 1795, when a treaty was formed at Greenville between major-general Anthony Wayne on the part of the United States, and the chiefs of the following tribes of Indians, *viz.* the Wyandots, Delawares, Chawanou, Ottawas, Chippewas, Putawatimes, Miamis, Eelriver, Weeas, Kickapoos, Pian-Kaſhaws, and Kaſkaſkias. By this treaty the Indians ceded a conſiderable territory to the United States, and the latter relinquiſhed their claims to lands that are particularly deſcribed. Preſents were made to the Indians of goods to the amount of 20,000 dollars; and the treaty ſtipulated the grant of goods every year thenceforward, to the amount of 9500 dollars, at firſt coſt in the United States, to be delivered to the Indians at ſome convenient place northward of the Ohio. Since this treaty, a trade has been opened by a law of congreſs with the forementioned tribes of Indians, on a liberal footing, which promiſes to give permanence to the treaty and ſecurity to the future inhabitants. Morſe's Geography. Harris's Journal of a Tour, &c. Boſton, 1805.

OHIO, the principal river in the ſtate above-deſcribed, ſeparating this ſtate and Indiana territory from Kentucky and Virginia on the S.E. and formed by the confluence of the Alleghany and Monongahela below Pittſburg. Both the names, Alleghany and Ohio, have the ſame meaning in different Indian languages; the former in the Delaware, and the latter in the Seneca, ſignifies the "fine, or fair river;" and the whole ſtream, from its head to its junction with the Miſſiſippi, was ſo denominated by theſe reſpective nations. Hence it was firſt named by the French, "La Belle Riviere." From Pittſburg it takes a N.W. courſe for about 25 miles, then turns gradually to the W.S.W., and purſuing that courſe for about 500 miles, winds to the S.W. for nearly 160 miles, and at length empties itſelf into the Miſſiſippi in a S.E. direction, about 1100 miles below Pittſburg, and nearly at the ſame diſtance above New Orleans, in N. lat. 36° 43′, or 37° 0′ 20″. It is very crooked in its courſe, but its general direction is S. 60° W. At fort Pitt, it is a quarter of a mile wide; 500 yards at the mouth of the Great Kanhaway; 1200 yards at Louiſville; and at the rapids, half a mile, in ſome few places below Louiſville, but its general breadth does not exceed 600 yards. In ſome places its width is not 400, and in one place particularly, far below the rapids, it is leſs than 300. Its breadth in no place exceeds 1200 yards, and at its junction with the Miſſiſippi, neither river is more than 900 yards wide. Its length, as meaſured according to its meanders by Capt. Hutchins, is as follows: From Fort Pitt

		Miles.
To	Log's Town	18½
	Big Beaver Creek	10¾
	Little ditto	13½
	Yellow Creek	11¼
	Two Creeks	21¾
	Long Reach	53¾
	End Long Reach	16½
	Muſkingum	26½
	Little Kanhaway	12¼
	Hockhocking	16
	Great Kanhaway	82½
	Guyandot	43¾
	Sandy Creek	14½
	Scioto	48¾
	Little Miami	126¼
	Licking Creek	8
	Great Miami	26¾
	Big Bones	32½
	Kentucky	44¼
	Rapids	77¼
	Low Country	155¾
	Buffalo River	64½

	Big Cave	42¾
	Shavanee River	52¼
	Cherokee river	13
	Maſſack	11
	Miſſiſippi	46
		1188

In common winter and ſpring floods, the Ohio affords 30 or 40 feet of water from the Miſſiſippi to Louiſville; 25 or 30 feet to La Torte's rapids; 40 above the mouth of the Great Kanhaway; and a ſufficiency at all times for flat-bottomed boats and canoes, to Fort Pitt. The inundations of this river begin about the latter end of March, and ſubſide in July, although they frequently happen in other months. Beſides the waters of many creeks, the Ohio receives in its courſe ſeveral rivers; *viz.* the Great and Little Kanhaway, or Kenhawa, the Great and Little Guyandot, the Great and Little Sandy, Licking, Salt, Cumberland, and Tenneſſee from the E. and S.; and the Muſkingum, the Hockhocking,

Hockhocking, the Great and Little Scioto, the Great and Little Miami, and the Wabaſh, from the N.

The *rapids* in the Ohio are ſituated in N. lat. 38° 8′, according to Hutchins's Survey; 705 miles below Pittſburg. They are occaſioned by a ledge of rocks, which extends acroſs the bed of the river. When the water is low, the greater part of the rocks becomes viſible, and the navigation is difficult; though there is a channel through which flat-bottomed boats can paſs in ſafety, conducted by a ſkilful pilot: but in the time of the freſhets, the rapids are hardly to be perceived by the navigator, except from the ſuperior velocity of the veſſel's movement; and then a 74 gun-ſhip might deſcend with the greateſt eaſe. The ſituation of the rapids is very delightful; and the town of Louiſville commands a grand view of them. In levelling their deſcent, it has been found to be 22½ feet in two miles, except at the rapids. The current of this river is gentle, its waters clear, and its boſom ſmooth and unbroken.

The numerous iſlands interſperſed in this river add much to the beauty of its appearance; but they embarraſs the navigation, particularly in low water, as they occaſion ſhoals and ſand bars. The extent of ſome of theſe iſlands is conſiderable; their ſoil is rich, and they are covered with a fine growth of trees. Morſe and Harris.

Ohio, the north-weſternmoſt county of the ſtate of Virginia, bounded E. by Waſhington county in Pennſylvania, and N.W. by the river Ohio, which ſeparates it from the ſtate of Ohio. It contains 4483 free inhabitants, and 257 ſlaves. Its chief town is Weſt Liberty.—Alſo, a county of Kentucky, containing 1121 inhabitants, of whom 122 are ſlaves.

OHIOPE, a ſmall northern tributary ſtream of Alatamaha river, in Oglethorpe county, Georgia, in America.

OHIOPIOMINGO, a tract of land in the ſtate of Kentucky, ſituated in Nelſon county, on the river Ohio, S.W. of Salt river.

OHIOPYLE Falls, a cataract of America, in Youghiogany river, about 20 feet in perpendicular height, and 80 yards wide, at the diſtance of 30 or 40 miles from the mouth of this river, where it mingles its waters with thoſe of the Monongahela.

OHITABOO, an iſland in the South Pacific ocean. S. lat. 9° 55′. W. long. 139° 6′.

OHLAU, a town of Sileſia, in the principality of Brieg, on the river Ohla, which riſes four miles S. of Munſterberg, and runs into the Oder at Breſlau. The town is ſituated in the midſt of marſhes, and ſurrounded with walls and ramparts. It has a large caſtle, a copper flatting mill, and two churches, one for Roman Catholics and another for Proteſtants. It has alſo a Poliſh church. Its vicinity yields great quantities of tobacco; 8 miles N.W. of Brieg.

OHLM, or Ulm, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz, on the Selz; 6 miles S.W. of Mentz.

OHM, a river of Germany, in the circle of the Lower Rhine, which runs into the Lahn, near Marpurg.

OHOULANG, a town of Thibet; 107 miles S. of Haratoube.

OHRA, a river of Germany, in the circle of Lower Saxony, which runs into the Unſtrutt, 6 miles N. of Erfurt.

OHRDRUF, a town of Germany, in the circle of Upper Saxony, and principality of Gotha, capital of the county of Glaichen. After having often ſuffered by fire, it is now in a flouriſhing ſtate by its numerous manufactures; 8 miles S.S.E. of Gotha.

OHRENBAU, or Ohrnbau, a town of Germany, in the circle of Franconia, and biſhopric of Aichſtatt; 6 miles S.S.E. of Anſpach.

OHRINGEN, or Oringawe, a town of Germany, in the circle of Franconia, and principality of Hohenlohe, on the Ohrn, which runs into the Cocher: this river divides it into the Old and New Town; it contains two churches and an hoſpital; 34 miles E.S.E. of Heidelberg.

OHRLE, a town of Germany, in the circle of Lower Saxony, and duchy of Bremen; 3 miles S.W. of Bremervord.

OHTAKARI Islands, a cluſter of ſmall iſlands on the E. ſide of the gulf of Bothnia. N. lat. 64° 6′. E. long. 23° 26′.

OI, a river of Ruſſia, which runs into the Yeniſei, N. lat. 55° 16′. E. long. 91° 34′.

OIA, a river of Ruſſia, which runs into the Obſkaia gulf, N. lat. 68°. E. long. 72° 24′.

OJA, a town of Sweden, in the province of Sconen; 21 miles S.S.E. of Lund.—Alſo, a town of Sweden, in the province of Smaland; 9 miles S.W. of Wexio.

OIBO, or Maoibo, one of the Querimba iſlands, in the Indian ſea, near the coaſt of Africa. S. lat. 12° 12′.

OICH-Loch, a conſiderable lake in the county of Inverneſs, Scotland, is ſituated in the great vale of that diſtrict, and conſtitutes part of the ſeries of lakes and rivers which extend acroſs the whole iſland, from the Moray Frith to the Sound of Mull. It is about four miles in length, and contains ſeveral beautiful little iſlands covered with trees. The banks of this lake riſe very gradually, and form a ſeries of ſmall bays on each ſide. From its eaſtern extremity iſſues the river Oich, which, after a courſe of five miles, diſcharges itſelf into loch Neſs, at the diſtance of 400 yards from the mouth of the river Tarff. The peninſula between theſe ſtreams is diſtinguiſhed as the ſcite of Fort Auguſtus. This is a regular fortreſs, defended by four baſtions, and has barracks capable of accommodating a garriſon of four hundred men. It is not, however, conſidered a place of any ſtrength, being commanded by the ſurrounding hills. The rebels ſtormed this fort in 1746, but not deeming it of importance to the ſucceſs of their cauſe, ſoon again abandoned it, after deſtroying the greater part of the fortifications.

OICHIL, a mountain of Scotland; 12 miles S.W. of Perth.

OJECK, a town of Poland, in the palatinate of Sandomirz; 12 miles S.S.W. of Sandomirz.

OJEON, a town of Japan, in the iſland of Ximo; 25 miles S.W. of Awa.—Alſo, a town of Spain, in the province of Granada; 3 miles N. of Marbella.

OJEREN, a lake of Norway, in the province of Aggerhuus; 24 miles long and two wide; 10 miles E. of Chriſtiania.

OJESTADS, a town of Norway; 24 miles N.N.E. of Chriſtianſand.

OIGNY, a town of France, in the department of the Cote d'Or; 12 miles S. of Chatillon ſur Seine.

OJIO, a town of New Navarre; 24 miles E. of Caſa Grande.

OIL, in *Chemiſtry* and the *Arts*. Oils are divided into two claſſes: A. *Volatile*, and B. *Fixed oils*. The latter into two orders; *a*, fat, and *b*, drying oils.

A. *Volatile or Eſſential Oils*.—Theſe are ſo called becauſe they are evaporable at a moderate heat without decompoſition, and becauſe in them the odour or fragrance, or as the old chemiſts called it, the *eſſence* of vegetables conſiſts. Oils of this kind are obtained generally from vegetables, and ſome varieties from animals. They are extracted from the roots,

leaves, flowers, ſeeds, and fruits of vegetables, but ſeldom from ſeeds with two cotyledons, which generally afford the fixed oils; while the huſk, or cover of the ſeed, is always more or leſs impregnated with volatile oil, the acrimony of which defends in ſome degree the rudiments of the young plant from the depredations of inſects. The volatile oils, which are procured from the fruits of the lemon, the orange, and the bergamotte orange, are thoſe which alone are capable of being obtained by expreſſion. For this purpoſe a ſmall wheel, with its circumference ſet with ſtout nails, is put in motion, and a lemon or orange is applied to it till the whole of the yellow outer rind is raſped away. The raſpings fall to the bottom of the caſe in which the wheel turns, and they are then ſqueezed between two plates of glaſs. By this gentle preſſure the eſſential oil flows from the ruptured cells into any adjoining veſſel, and is there ſuffered to reſt till the water and other impurities have ſubſided. In a way ſimilar to this is obtained in India the precious perfume called the oil or "otter" of roſes. For this purpoſe a clean caſk or glazed earthen jar is filled with roſe-leaves ſeparated from its calyces, which are covered with ſpring-water. The veſſel is then ſet in the ſun for two or three days, and brought under cover in the night. At the end of the third or fourth day ſmall particles of yellow oil will float on the ſurface of the water, which in a week will have accumulated into a thin ſcum: this ſcum is taken up by a little cotton tied to the end of a ſtick, and ſqueezed into a ſmall phial.

Eſſential oils are generally obtained by diſtillation. The freſh herbaceous plant, or the dried plant, previouſly macerated for a few hours in water, or the bark or wood raſped or cut into ſhavings, and macerated for ſeveral days, are cloſely rammed down in a tinned copper ſtill or alembic; and when covered with water, the head of the ſtill is luted on and the refrigeratory filled with cold water, and then the fire is lighted and ſo regulated as to keep the contents of the ſtill conſtantly ſimmering, without boiling. The ſteam condenſed in the worm will form a ſmall ſtream of water, which is to be collected in proper veſſels, till it comes off nearly inſipid and inodorous; and then the diſtillation is ſtopped. The firſt part of the produce, as it is turbid from ſuperſaturation with eſſential oil, is kept for ſome hours in a cold place, during which time the exceſs of oil will ſeparate from the water, and either float on the ſurface or ſink to the bottom, according to its ſpecific gravity. The oil is completely ſeparated from the diſtilled water by an inſtrument called the Italian recipient; and the whole of the water produced by the firſt diſtillation is employed in the next, inſtead of plain water; ſo that thus the produce of oil in the ſecond diſtillation will exceed that of the firſt, by the whole quantity held in permanent ſolution by the water of the former proceſs. By this proceſs, the amount of oil yielded by equal quantities of the ſame ſubſtance will form a conſtantly increaſing ſeries, till the whole of the water drawn off by each diſtillation is completely ſaturated with oil. It is not till the ſeventh, or even ſometimes the tenth diſtillation, that the produce of oil attains its maximum. Eſſential oil may be procured not only from odorous vegetables themſelves, but from ſuch of the immediate products of vegetation as poſſeſs any odour; ſuch are the balſams and many of the reſins and gum reſins. The peculiar odour of vegetables, when not in a ſtate of decompoſition, depending on the volatile oil they contain, it is plain that the odours of the oil themſelves are equally various. Their taſte is exceedingly hot and pungent, and in ſome, particularly the oil of peppermint, followed by a remarkable ſenſation of coldneſs, though the thermometrical temperature undergoes no change. The acrimony of ſome of the oils, as the oil of cloves, is ſo great as actually to deſtroy the outer ſkin of the tongue and of other ſenſible parts. The colours of eſſential oils are various, ſome being blue, others green; but the uſual colour is light yellow, verging more or leſs by long keeping to reddiſh-brown. Other ſtriking characters of volatile oils are that they are liquid, more or leſs at different temperatures, ſometimes thick and glutinous like the expreſſed oils, and ſometimes ſolid and in cryſtals. In the latter ſtate they approach the nature of reſins. They are highly combuſtible, producing much ſmoke, condenſing into ſoot. They are alſo of an agreeable ſtrong ſmell, and of a pungent acrid taſte. They are volatile at a heat leſs than 212°. And they give a greaſy ſtain to paper, but evaporate without leaving any mark. Volatile oil, however, may be detained in a higher heat by mechanical mixture with dry clay or ſand; and then it undergoes a partial decompoſition, carburetted hydrogen being given out, and a little charcoal remaining in the receiver; the undecompoſed reſidue, if ſubjected three or four times ſucceſſively to ſimilar treatment, will be entirely deſtroyed.

The following table exhibits the moſt prominent properties of ſome of the volatile oils.

TABLE of Volatile Oils.

Names.	Colour.	Specific Gravity.	Conſiſtency at 60°. Freezes at 14°.	Odour.
Turpentine	None.	·792	Fluid as water.	Strong.
Juniper	Green.	.611	Very fluid.	Strong ſmell.
Roſemary	None.	·934	Thin liquid.	Like the plant.
Mint	None.	·975	Very fluid.	Agreeable.
Cloves	None.	1.034	Oily and very fluid.	Very fragrant.
Lemon	Yellow.		Thin liquid.	Very agreeable.
Orange	Yellow.	.888	Ditto.	Nearly ſimilar.
Cinnamon	Yellow.	1.035	Oily and leſs liquid.	Pleaſant.
Saſſafras	None.	1.094	Oily.	Like the root.
Fennel		·997	Becomes ſolid at 50°.	
Tanſy		·946		Very ſtrong.
Dill		·994		
Carraway	None.	·94		Very ſtrong and pungent.
Penny Royal		·978		Agreeable, like the plant.
Cummin		·975		

Nutmegs

Names.	Colour.	Specific Gravity.	Confiſtency at 60°. Freezes at 14°.	Odour.
Nutmegs - -	None.	·948	Like butter.	Very pleaſant.
Aniſeed - -	None.		Becomes ſolid at 50°.	Very ſtrong.
Thyme - -	Brown.		Cryſtallizes.	Like camphor.
Spike - -	Yellow.	·936		Very ſtrong.
Lavender - -	None.		Thin liquid.	Very agreeable.
Origanum - -		·94		Very ſtrong and acrid.
Wormwood - -	Green.			
Camomile - -	Blue.			
Hops - - -	Green.		Like butter.	Like the flower.
Parſley - -	Green.			
Bergamotte - -	Yellow.		Not oily. Is ſolid at 23°.	Very pleaſant.
Cardamom - -	None.		Oily.	
Mace - -			Oily.	Agreeable.
Roſes - -	None.			
Peppermint - -	Green.		Thin liquid.	Very agreeable.
Savine - -	None.			Diſagreeable.
Pepper - -	None.		Like butter.	Very acrid.

When the volatile oils are recently diſtilled they evaporate without leaving any reſiduum. They are diſtilled with greater facility when water or alcohol is preſent. After they have been expoſed to the air for ſome time they do not entirely evaporate, but a ſlight reſiduum is left of the nature of reſin. When deprived of heat to a certain extent they become ſolid, having an unctuous appearance. Some of them aſſume the cryſtalline form.

It has been aſſerted by Tingry, that light has the property of increaſing the abſolute weight of the volatile oils when expoſed in a cloſe glaſs veſſel, the air at the ſame time being excluded. This fact, however, ought to be doubted, till confirmed by ſtronger evidence. This he attributes to the fixation of light, a thing at preſent unknown to chemiſts. The eſſential oils, eſpecially the more volatile of them, deoxygenate atmoſpheric air very completely, as was firſt aſcertained by Dr. Prieſtley, and this circumſtance partly accounts for the uneaſy ſenſations experienced by moſt perſons when in a cloſe newly painted room.

The action of oxygen upon theſe bodies is very conſpicuous. They become viſcid, and aſſume a yellow colour. The colour becomes deeper, more eſpecially if it is expoſed to the ſun, and the oil ultimately aſſumes the form of reſin. In thick oils another change takes place; a weakly acidulous water is produced, and priſmatic cryſtals are depoſited; the reſidue of the oil becoming, in the mean time, concrete. Theſe cryſtals, which have been occaſionally miſtaken for camphor, are ſlightly ſoluble in hot water, and more ſo in alcohol; to which they communicate the property of reddening vegetable blues; when gently heated, they ſwell and cryſtallize in needles by cooling; when heated by the blowpipe they evaporate, but do not inflame; from theſe properties they have been conſidered as an acid very analogous to the benzoic. Some eſſential oils afford real camphor by evaporation, as Prouſt has ſhewn. (See CAMPHOR.) If the maſs ſo changed into reſin be ſubjected to diſtillation, an oil ſimilar to the original comes over, leaving behind a reſin of greater hardneſs, and more infuſible than the original maſs. Almoſt all the ſubſtances denominated reſin are capable of affording a portion of an eſſential oil by the action of heat, the reſin becoming harder and leſs fuſible. It is on theſe facts that the art of japanning depends. If the ſurface of any body be covered with common tar, and then expoſed to the heat of a ſtove for a certain time, the oily part evaporates, leaving a hard coating, which does not ſoften at a heat ſhort of that which would decompoſe it, and at the ſame time ſo hard as not to be penetrable by the nail. Common pitch and reſin are of different degrees of ſoftneſs, according to the extent to which the diſtillation has been carried. The change produced in the volatile oils, by expoſure to the air, has been ſuppoſed to ariſe from the abſorption of oxygen, but in all probability this is not the fact. That oxygen diſappears is undeniable, but that it is retained in the body is doubtful. We are informed by Fourcroy, that drops of water are formed when oxygen is expoſed over oil of turpentine. Hence it is highly probable, that the oxygen combines with the hydrogen of the oil, forming water, which leaves a compound having leſs hydrogen, and in conſequence more fixed and hard.

The volatile oils, from the great quantity of hydrogen they contain, take fire with great facility, and burn with a copious white flame, producing much ſoot. If the products of combuſtion be collected, they will be found to conſiſt of water and carbonic acid, derived from the carbon and hydrogen of the oil, with the oxygen of the atmoſphere.

It is by this means that we are to expect an analyſis of theſe ſubſtances, an object which has not yet been accompliſhed, but which is very deſirable.

The volatile oils do not undergo any change with hydrogen or carbon. They combine to a certain extent with ſulphur, by which they acquire a browniſh colour, and diſagreeable ſmell. This ſulphurized oil gives out on diſtillation ſulphuretted hydrogen; it is often called "balſam of ſulphur."

It is ſaid that theſe compounds are decompoſed by heat with a violent efferveſcence, which is ſuppoſed to ariſe from the ſulphur combining with the hydrogen, forming ſulphuretted hydrogen.

Camphor, which may be deemed a concrete volatile oil, combines with phoſphorus by trituration. This compound may afterwards be diſſolved in moſt of the volatile oils. The ſolution is luminous when expoſed to the air, ſo as to tell the hour of the night.

Water has little action upon the volatile oils. The water, however, diſſolves as much as gives it a ſtrong taſte of the oil. When the oil is firſt dropped upon ſugar, and this put into water, a greater quantity is retained. Advantage is frequently taken of this fact in pharmacy.

They are moſtly ſoluble in alcohol and ether, though in limited proportions.

The

The alkalies have much leſs action upon the volatile oils than upon the fixed oils. They are more ſuſceptible of combining with theſe bodies, in proportion as they approach the ſtate of reſin. Common turpentine combines with potaſh, while oil of turpentine is but with difficulty made to unite with it. This has been called *Starkey's ſoap*.

We are in poſſeſſion of ſome facts relative to the action of acids upon the oils.

The ſulphuric acid diſſolves them, and mutual decompoſition takes place. The colour becomes dark, and charcoal is at length depoſited. When water is poured upon the ſolution, a reſinous maſs becomes ſeparated. Hence it appears, that the oxygen of the ſulphuric acid produces a ſimilar change with the oxygen of the atmoſphere.

The nitric acid, when poured upon moſt of the eſſential oils, cauſes them to inflame with great violence, leaving behind a ſpongy coal of a brown colour. The acid ſhould be very ſtrong for this experiment.

Muriatic acid ſlightly diſſolves theſe ſubſtances, but we have no facts as to their mutual change.

It may eaſily be conceived, that many of the metallic oxyds will produce the ſame changes upon the volatile oils which are produced by the acids, and the oxygen of the atmoſphere. The facility with which lead, mercury, and manganeſe give up their oxygen, offers a ready method for an accurate analyſis of theſe bodies.

The volatile oils are uſed in medicine, and are conſidered ſtimulants. They are alſo uſed as perfumes; and in the compoſition of varniſhes and oil paints.

Fixed, Vegetable, or Unctuous Oils.—The fixed oils have the following characters:

1. They are greaſy to the touch.

2. They are moſtly liquid, or rather in the ſtate of a moderately thick, but not viſcid, fluid, at the common temperature of the atmoſphere, but become ſolid at certain degrees below.

3. They do not boil at leſs than 600°.

4. They take fire at a certain temperature, and burn with different degrees of brilliancy.

5. They are not acrid like the volatile oils, but frequently almoſt inſipid, or poſſeſſing a mild ſub-nauſeous taſte, and a peculiar flavour, according to the vegetables from which they are produced. Their colour, when recent, has more or leſs of a greeniſh tinge, which by keeping becomes yellow, and in ſome inſtances orange-coloured, verging on red. Their ſpecific gravity is uſually between that of alcohol and water, as they ſink in the former, and float on the ſurface of the latter. Of theſe fluids, there is no circumſtance in which they differ ſo much as in the temperature at which they congeal: ſome continue ſolid at the higheſt atmoſpherical temperature, as palm oil, and the reſt of the vegetable "butters," as they are called from this circumſtance; others require being cooled down to the freezing point of water; and others, again, are capable of enduring a much greater degree of cold without becoming ſolid.

6. They are inſoluble in water and alcohol.

7. They leave a ſtain on paper, which cannot be removed by evaporation.

Fixed oils are ſo called, becauſe they are incapable of being volatilized by heat without decompoſition. When any of them, *e. g.* olive oil, is heated in a cloſe diſtillatory apparatus, as ſoon as the fluid has arrived at its boiling point, a white vapour is diſengaged, conſiſting of oil, carburetted hydrogen, and carbonic acid. The firſt of theſe is for the moſt part condenſed in the receiver; while the other two, retaining in ſolution a portion of oil, eſcape in the form of permanent gas: and when every thing volatile has been driven off, nothing remains in the retort but a little charcoal. The oil which is found in the receiver is lighter, more limpid and volatile, than that from which it was procured; and theſe qualities are obſerved to increaſe by each ſucceſſive diſtillation; carbon and carburetted hydrogen being diſengaged as at firſt. By continuing this proceſs with the product of each diſtillation, the oil at length entirely diſappears, being partly decompoſed, and partly carried off in ſolution by the carburetted hydrogen gas.

They are principally procured from the cotyledons of ſeeds, and ſometimes, though rarely, from the pulp or fleſh of fruits. The ſubſtance containing the oil is beaten to a pulp, and then heated to a certain temperature. It is then ſubjected to the action of a ſtrong preſs, to force out the oil. Much of the mucilage is carried off with the oil. This is more particularly the caſe when the pulp is heated. If it be preſſed cold, the oil is much freer from colour, and in a ſtate of greater purity; but the quantity obtained is leſs. The oil obtained in this way is ſaid to be *cool drawn*. If the heat be too great, the oil will be more coloured. The kernels of the common nut, the walnut, and the hickory nut, yield an abundance of oil: it is alſo expreſſed from the ſeeds of the lint, the rape, the poppy, and the ſun-flower; and in great abundance from the exterior ſubſtance of the olive. All the fixed oils, except the latter, are obtained from the cotyledons of ſeeds; and it is remarkable that no ſeed with one cotyledon affords a fixed oil. Oil may be extracted not only by preſſure, which is the moſt common method, but by immerſion in hot water. In this latter caſe, the oil ſeparates from the other ingredients with which it is naturally mixed, and riſes by the force of gravity to the ſurface of the water, from which it is ſkimmed off. Recently drawn oil is more or leſs impure, on account of its containing a variable proportion of mucilage, fecula, and perhaps other ſubſtances: of theſe a part is always depoſited by reſt, eſpecially if the contact of the air is not wholly excluded; but another portion remains in permanent ſolution; and to this that partial ſpontaneous decompoſition in oils, called "rancidity," is principally owing. They are alſo obtained from animals, ſuch as whale oil and neat's-foot oils.

All animals, except thoſe included in the claſs of inſects, contain oil; the quantity of which, as well as its ſituation in the body, is ſubject to conſiderable variety. (See Cellular *Membrane*, Adeps, and Sebacic *Acid*. See alſo *Anatomy of* Birds, Fish, and Mammalia.) While the fat remains in the living body, it is always in a fluid or ſemi-fluid ſtate; but its conſiſtence changes, when it is extracted and expoſed to the common temperature. The oil or fat, inveſting the kidnies of quadrupeds, is called ſuet or tallow, and is the hardeſt and moſt ſolid of any; the next in hardneſs is the fat of the bones, and that in which the muſcles are imbedded is the next in degree: the fat of the hog, called "lard," is the leaſt ſolid. The fat of birds is ſeldom ſo ſolid as hog's lard, and in many ſpecies is actually fluid. The fat or oil of fiſh is almoſt always fluid at the common temperature. There is alſo fat in the yolk of eggs, which may be extracted by ſimple preſſure, after the yolk has been coagulated by heat.

Animal oil is obtained in its pureſt ſtate by ſhredding freſh ſuet, and liquefying it in boiling water, and then paſſing it through a piece of thin gauze, in order to ſeparate the cellular membrane. Thus purified, its colour is yellowiſh-white: it is moderately hard, of a mild taſte, and almoſt deſtitute of odour or flavour; it is combuſtible, like the fixed vegetable oils, and agrees with theſe in the changes produced upon it by the alkalies and other chemical re-agents.

All

All the animal oils belong to the claſs of unctuous or fat oils, none of them being either drying in themſelves, or capable of becoming ſo by means of litharge and other ſubſtances. Fat, expoſed to dry diſtillation, when it acquires the temperature of about 400°, emits a white acrid and diſagreeable vapour: as the heat increaſes, ſome of the oil comes over into the receiver, and that which remains in the retort acquires a blackiſh tinge; empyreumatic, acetous, and ſebacic acids manifeſt themſelves, together with carburetted hydrogen and carbonic acid of a very offenſive odour. Hence it is inferred that there is a real difference between animal and vegetable oils, though it has not been pointed out by chemical analyſis. The coarſer kinds of animal oil, extracted by putrefaction and a ſtrong heat, poſſeſs a much more diſagreeable odour than any of the vegetable oils; and, when rancid, diſengage ammonia by the action of the fixed cauſtic alkalies, in which they alſo differ from the latter. The fiſh oils, always rancid, are for the moſt part thick and glutinous, which renders them in ſome degree unfit for burning, and ſome other uſes to which they are applied. Many attempts have been made to meliorate them; and it appears by the experiments of Mr Doſſie, that they may be conſiderably improved by means of fixed alkali and chalk, by which the albumen and gluten are thrown down, and the ſupernatant oil, after due reſt, may be poured off in a fluid ſtate, and very ſenſibly amended in conſiſtence, odour, and fitneſs for burning. Animal oils are ſubſtances of very great economical importance. They are uſed as food, and in medicine as the baſis of various unguents: they are largely employed in the manufacture of ſoap, and alſo for burning either in lamps or in the form of candles. Aikin's Dict.

Whale oil is much contaminated by different animal matters, to which it owes its diſagreeable odour. It has, however, been ſo purified as to poſſeſs leſs ſmell and taſte than the beſt olive oil.

All the fixed oils are of leſs ſpecific gravity than water; and ſince they do not combine, the former muſt float upon the ſurface of the latter.

The fixed oils cannot be diſtilled without decompoſition. They boil at 600°: a vapour comes over, which condenſes into an oil, which is different from the original. An inflammable gas is diſengaged, and ſome coal depoſited. This is ſome proof that decompoſition takes place. From theſe facts we may fairly conclude, that the oil of lamps and candles, when in the act of burning, undergoes decompoſition. The inflammable gas and the vapour conſtitute the volatile part which makes the flame, while ſome carbon is ſeparated, which lodges in the wick.

Fixed oils are divided into two orders: (*a*), *fat oils*, and, (*b*), *drying oils*.

(*a*). *Fat Oils*.—Theſe are ſuch as, when expoſed to the air for a certain time, firſt become viſcid, and ultimately concrete, having the appearance of tallow, and in every reſpect ſimilar to fat. This oil will be more or leſs hard, according to the time expoſed: it at the ſame time acquires a diſagreeable odour, to which we give the name of rancidity. Of theſe kinds we may mention olive oil, almond oil, and that extracted from rape ſeed, called rape oil. This change is more rapidly brought about by dilute nitric acid, or any ſubſtance which affords oxygen. It has been ſuppoſed that the combination of the oxygen with the oil gives to it the concrete form. It is, however, to be regretted that we have not as yet learned from any experiments, whether the abſolute weight of the oil be increaſed or diminiſhed by the agency of the oxygen. It ſeems moſt plauſible to ſuppoſe, that the oxygen combines with a portion of hydrogen of the oil, forming water, leaving the remainder more concrete and leſs fuſible. Olive oil, by treating it with nitric acid, may be rendered equally infuſible with ſpermaceti.

The fat oils combine with the alkalies, earths, and moſt metallic oxyds, forming ſoaps. See Soap.

They are not miſcible with water, except through the medium of ſugar, ſtarch, or gum. With the two latter they form compounds, called *emulſions*.

They do not combine with many of the combuſtible bodies. They unite with ſulphur, forming a dark brown compound of a diſagreeable ſmell. On cooling, ſome of the ſulphur is depoſited in cryſtals. Phoſphorus combines with ſeveral of the fat oils. Olive oil, when rubbed with phoſphorus in a mortar, diſſolves a portion of it. The ſolution, when expoſed to the air, by opening the bottle containing it, becomes very luminous. Any ſubſtance ſmeared with it ſhines for ſome time, but no perceptible heat is produced.

When concentrated ſulphuric acid is poured upon the fixed oils, decompoſition ſpeedily enſues. The products are water, carbon depoſited, giving a black colour. The ſulphur is alſo depoſited, and ſome acetic acid formed. When concentrated nitric acid is poured upon oils, the action is conſiderable; the oil takes fire, and burns, leaving a ſpongy coal behind. If the acid be dilute, as has been obſerved, it converts the fat oils into fat like tallow.

The fixed oils combine with ſome of the metals. A leaden veſſel ſoon becomes corroded by oil contained in it; the oil at the ſame time becoming thicker. They have ſcarcely any action upon tin; hence the uſe of the latter metal in preference to the former for oil veſſels. Oil has alſo a decided action upon iron, as we ſee in the axle-trees of carriages, and in all inſtances in which oil is uſed with iron to leſſen friction.

b. Drying Oils.—Theſe oils poſſeſs properties moſtly common to both, but differing in ſome particulars. They, like the fat oils, become concrete by the action of oxygen; but inſtead of aſſuming an opaque fatty appearance, they retain their tranſparency, and acquire the flexible property of horn.

The varieties poſſeſſing this property are the oils of nut, poppy, and lint.

Theſe oils are leſs fitted for combuſtion than the fat oils, but are of great uſe for paints and varniſhes, and making printers' ink. When uſed for the latter purpoſe the nut oil is preferred, on account of its not turning yellow. It is firſt ſet on fire, and allowed to burn for a ſhort time; it is then covered by a lid to extinguiſh it, and allowed to boil for ſome time. By this treatment it loſes its greaſy quality, becomes thick and ropy, and is more miſcible with water, a property of great importance in the above application. Drying oils become more ſuſceptible of the concreting quality by being boiled with litharge, or almoſt any ſubſtance containing oxygen. Doubtleſs in this proceſs the oxygen of the lead combines with the hydrogen of the oil, while the lead combines with the oil, to which it gives a dark colour, and makes it thicker. Acetat of lead, and other metallic ſalts, produce the ſame change.

When oil is mixed with the black oxyd of manganeſe, it ſome time after takes fire. This ariſes from a more rapid combination of the oxygen of the oxyd with the hydrogen of the oil.

The compoſition of the fixed oils has been given by Lavoiſier, but it is not to be relied upon. He makes it conſiſt of 79 carbon, and 21 hydrogen.

Another ſpecies of oils is found in ſome vegetables, which have an acrid taſte, and diſſolve in alcohol, like the volatile

volatile oils, but are not ſo volatile as to admit of diſtillation. The vegetable containing the oil is infuſed in alcohol, which diſſolves the oil. The alcohol is afterwards diſtilled from the oil.

Theſe oils are ſaid to be poiſonous, which appears to be their moſt diſtinguiſhing character. An oil of this kind is obtained from the root of the helleborus hyemalis, and another is found in tobacco.

Oils, *Empyreumatic*.—Theſe approach the nature of volatile oils, and are formed during the diſtillation of vegetable and animal ſubſtances. They have properties nearly allied to tar, and afford, by a ſecond and careful diſtillation, a liquid volatile oil, not much unlike the oil of common tar, which has many properties in common with oil of turpentine. A ſimilar ſubſtance is obtained from pit-coal by diſtillation, which oil belongs alſo to this claſs.

The colour of empyreumatic vegetable oil is yellowiſh-red, paſſing into blackiſh-red; it has a ſtrong odour, and an acrid empyreumatic taſte; it is more volatile than the fixed oils, but leſs ſo than the proper eſſential ones; by re-diſtillation with a little water it almoſt wholly loſes its colour, and becomes more volatile than before, though ſtill poſſeſſed of much of its empyreumatic flavour. See Aikin's Dict.

The uſe of oil in ſtopping the violent ebullition of various ſubſtances, may be very great in many occaſions of life. It is well known that if a mixture of ſugar, honey, or the like, be boiling on the fire, and in danger of riſing over the ſides of the veſſel, the pouring in a little oil immediately makes it ſubſide. In many caſes, the marking a circle round the inſide of a veſſel, in which a liquor of this kind is to be boiled, with a piece of hard ſoap, ſhall, like a magic ring, confine the ebullition to that height, and not ſuffer it to ſtir any farther. This is wholly owing to the oil, or fat, contained in the ſoap; but there is, beſides theſe, another very important uſe of oil, on a like occaſion, which is the pouring a little of it on any metallic ſolution, while making; this reſtrains the aſcent of the noxious vapours; preſerves the operator from danger; and, at the ſame time, by keeping down the evaporating matter, gives redoubled ſtrength to the menſtruum.

Pliny has mentioned an extraordinary effect of oil, in ſtilling the ſurface of water when it is agitated with waves, and the uſe made of it by the divers, for this purpoſe. "Omne," ſays he, "oleo tranquillari," &c. lib. ii. cap. 103. and Plutarch, in Quæſt. Natur. aſks, "Cur mare oleo conſperſum perlucidum ſit et tranquillum?" Pliny's account ſeems to have been either diſcredited or diſregarded by our writers on experimental philoſophy, till it was confirmed by ſeveral curious experiments of Dr. Franklin, which were publiſhed in the year 1744.

The property of oil above-mentioned has, however, been well known to modern divers and dredgers for oyſters, at Gibraltar, and elſewhere. The divers in the Mediterranean, in particular, deſcend, as in Pliny's time, with a little oil in their mouths, which they now and then let out; and which, on riſing to the ſurface of the ſea, immediately renders it ſmooth, ſo as to permit the light to paſs through the water, undiſturbed by various and irregular refractions.

The Bermudians, it is ſaid, are enabled to ſee and ſtrike fiſh, which would be concealed from their view, through the roughneſs of the ſea, by pouring a little oil upon it. And the Liſbon fiſhermen effect a ſafe paſſage over the bar of the Tagus, by emptying a bottle or two of oil into the ſea, when the ſurf is ſo great as to endanger its filling their boats. Our ſailors have alſo obſerved, that the water is always much ſmoother in the wake of a ſhip that hath been newly tallowed than it is in one that is foul.

Dr. Franklin was led, by an accidental obſervation made at ſea in 1757, to attend particularly to Pliny's account; and the various informations which he afterwards received relating to it, induced him to try ſome experiments on the ſubject. Standing on the windward ſide of a large pond, the ſurface of which was rendered very rough with the wind, he poured a tea-ſpoonful of oil on the water. This ſmall quantity produced an inſtant calm over a ſpace of ſeveral yards ſquare, which ſpread amazingly, and extended itſelf gradually, till it reached the lee-ſide, making all that quarter of the pond, perhaps half an acre, as ſmooth as a looking-glaſs. On repeating this experiment, which conſtantly ſucceeded, one circumſtance ſtruck him with particular ſurprize; this was the ſudden, wide, and forcible ſpreading of a drop of oil on the face of the water, which, he adds, "I do not know that any body has conſidered."

When a drop of oil is put on a looking-glaſs, or poliſhed marble, it ſpreads very little: but on water it inſtantly expands into a circle extending ſeveral feet in diameter, becoming ſo thin as to produce the priſmatic colours for a conſiderable ſpace, and beyond them ſo much thinner as to be inviſible, except in its effects of ſmoothing the waves at a much greater diſtance. It ſeems, ſays Dr. Franklin, as if a mutual repulſion between its particles took place as ſoon as it touched the water, and a repulſion ſo ſtrong as to act on other bodies ſwimming on the ſurface, as ſtraws, leaves, &c. forcing them to recede every way from the drop, as from a centre, leaving a large clear ſpace. The quantity of this force, and the diſtance to which it will operate, the author ſays, he has not yet aſcertained; but he thinks it a curious enquiry, and wiſhes to underſtand whence it ariſes. In endeavouring to account for the ſingular effects of oil, Dr. Franklin obſerves, that there ſeems to be no natural repulſion between water and air, ſo as to keep them from coming into contact with each other. Therefore air, in motion, which is wind, in paſſing over the ſmooth ſurface of water, may rub, as it were, on that ſurface, and raiſe it into wrinkles, which, if the wind continues, are the elements of future waves. The ſmalleſt wave does not immediately ſubſide, but in ſubſiding raiſes nearly as much of the water next to it. A ſmall power, continually operating, will produce a great action: ſo that the firſt raiſed waves, being continually acted upon by the wind, are, though the wind does not increaſe in ſtrength, continually increaſed in magnitude, riſing higher and extending their baſes, ſo as to include a vaſt maſs of water in each wave, which, in its motion, acts with great violence. But if there be a mutual repulſion between the particles of oil, and no attraction between oil and water, oil dropt on water will not be held together by adheſion to the ſpot on which it falls; it will not be imbibed by the water; but be at liberty to expand itſelf and ſpread on a ſurface, that prevents, perhaps, by repelling the oil, all immediate contact; the expanſion will continue till the mutual repulſion between the particles of oil is weakened, and reduced to nothing by their diſtance.

Dr. Franklin imagines, that the wind blowing over water, thus covered with a film of oil, cannot eaſily catch upon it, ſo as to raiſe the firſt wrinkles, but ſlides over it, and leaves it as ſmooth as it finds it. It moves a little the oil, indeed, which being between it and the water, ſerves it to ſlide with, and prevents friction: hence the oil dropt on the windward ſide of the pond proceeds gradually to leeward, as may be ſeen by the ſmoothneſs it carries with it quite to the oppoſite ſide: for the wind, being thus prevented from raiſing the firſt wrinkles, which he calls the elements of waves, cannot

produce

produce waves, which are to be made by continually acting upon and enlarging thoſe elements, and thus the whole pond is calmed.

Upon the whole, there is great room to ſuppoſe (notwithſtanding the partial failure of an experiment made at Portſmouth, by Dr. Franklin, and others), that ſea-faring people may derive advantages from uſing oil on particular occaſions, in order to moderate the violence of the waves, or to leſſen the ſurf, which ſometimes renders the landing on a lee-ſhore dangerous, or impracticable.

To this purpoſe we are informed that the captain of a Dutch Eaſt India ſhip, being overtaken by a ſtorm, found himſelf obliged, for greater ſafety in wearing the ſhip, to pour oil into the ſea, to prevent the waves breaking over her, which had an excellent effect, and ſucceeded in preſerving her. Phil. Tranſ. vol. lxiv. part. 2. p. 445, &c.

Oil, in *Agriculture*, a fatty unctuous material, obtained from animal as well as vegetable ſubſtances. Theſe matters are diſtinguiſhed into different kinds, as ethereal or eſſential, and fat or fixed oils: the former are acrid, volatile, odoriferous, and exiſt in the plants in the ſame ſtates in which they are found; while the latter are fixed, deſtitute of odour, and mild to the taſte. Theſe laſt, when kept a long time, corrupt and become rancid. They do not act upon earths, but readily combine with alkaline ſalts, with which when cauſtic they form vegetable ſoaps.

Though theſe matters cannot be employed by the farmers in their ſimple ſtates, as being too expenſive, and having rather a noxious or poiſonous effect, than a beneficial one on the growth of plants, they may frequently be uſed in the condition of compoſts with advantage, as has been the caſe in the application of various of the groſſer ſorts of materials of this nature, ſuch as thoſe of whale blubber, the bottoms and refuſe of oil caſks, &c. when blended with earthy materials, ſo as to be laid upon the land in an even and regular manner. And in this ſtate of combination they have been found, by the experiments of different cultivators, to form very ſtrong and powerful manures.

The account of Mr. C. Baldwin's trials made with the bottoms or *foots* of oil, and a rich thick South-ſea whale oil, in the whole ſixty gallons, is thus ſtated.

Having a platform or bottom of twenty loads of mould, with eight loads of dung on it, he carried on three loads of light ſandy mould, and one load of brick and mortar rubbiſh, ground fine, and having mixed theſe well, and made a kind of diſh of it, about five feet wide and ten feet long, with a ladle he had put over it one-half of the oil. It was in Auguſt, and the warmth of the ſun ſoon made the thick oil ſoak into the compoſt, when it was directly thrown up in a heap, broke down again, and by five or ſix turnings well mixed together, and left in a heap two days, when it was ſpread equally over the whole dunghill; twenty loads more of good mould were then carried on, eight loads of dung, and the remaining thirty gallons of oil were mixed as before, in ſandy mould, and brick and mortar rubbiſh, and equally ſpread over, and the whole was covered by trimming the four ſides of the dunghill, and throwing it on the top. And thus the dunghill lay more than two months, when it was cut down by mattocks, carefully broke, well mixed, and turned over. The end of March it was carried on the field, ſpread and ploughed in; it lay about a fortnight, and was then ploughed again, and on the 22d of April it was drilled with the Rev. Mr. Cooke's excellent drill. The field was drilled with barley, two buſhels to the acre; the crop came up in a moſt even and beautiful manner; every ſeed was up within forty-eight hours of each other; all was ripe at the ſame time, and, from a couple of months after ſeed-time to harveſt, was rated by all who ſaw it, and it was ſeen by many, as a ſixty buſhel crop. At harveſt, three rows were cut acroſs the field, directly thraſhed and meaſured; one load out of thirteen was alſo thraſhed and meaſured, and both ſtated the crop to be ſixty buſhels; but to wave all poſſibility of diſpute or doubt, he is content to ſtate the crop at ſeven quarters *per* acre. As to the quality of the barley, he could here cite the opinion of one of the moſt eminent brewers in London, who ſaw the crop growing, and declared he would readily give 1000*l.* to be aſſured that all the barley crops in the kingdom were of equal burthen and weight; five quarters of it have been lately ſent to Nethrapps, in Norfolk, as ſeed-barley, under the denomination of 15 comb-barley; and an eminent maltſter tells him it weighs 220lbs. *per* ſack, or 55lbs. *per* buſhel, Wincheſter meaſure. It is added, that among the many gentlemen and farmers who ſaw the crop on the ground, was the celebrated Mr. Bakewell; he came with three or four others, and walking down the field, obſerved the hedge and bank; the bank, upon being touched with a ſtick, run down as ſand and gravel generally do, and Mr. Bakewell being aſked his opinion of the value of the land, if he does not miſtake, valued it at 18*d.* *per* acre, but turning to the crop, and deſiring his friends to do ſo alſo, he admitted that it ſeemed as if growing on land of 15*s.* or 20*s.* *per* acre. He muſt not omit ſaying that the barley followed oats, upon a lay of ſix years old; that the land was, as is too common in ſuch caſes, much infeſted with the little red or wire worm, and that the oats ſuffered much from them; when they were ploughing for the barley the firſt time, he obſerved many turned up by the plough, when a diſtant ray of hope inſtantly darted upon his mind, that the ſoil in its then ſtate, or from its ſtrong effluvium, might prove obnoxious to them, and he is happy in ſaying, that the barley did not ſuffer from them in the leaſt.

It is further ſtated, that he is trying the experiment in Hampſhire, having laſt autumn made up a dunghill, with twenty gallons of oil, on one-third of it for a ſix-acre field, which is now drilled with peaſe.

And he concludes by obſerving, that it is well known that all animal ſubſtances, in a ſtate of corruption, wonderfully promote vegetation, and are the actual food of plants. The whale-oil which he uſed is an animal ſubſtance, perhaps the richeſt part of the animal; whether he uſed enough, or what is the proper quantity *per* acre, experience muſt point out; ſay he uſed eight loads of mould, three or four loads of dung, and twelve gallons of whale-oil *per* acre. That oil applied to land, as a food for plants, in its crude ſtate, acts as a poiſon he cannot deny; but his proceſs is very different: he believes that oil, particularly animal-oil, is the pabulum of plants, that is, oil ſubtilized by the ſalts in a compoſt dunghill, left there a conſiderable time in a ſtate of putrefaction, and until the whole is become putreſcent; then he believes he has got the beſt and richeſt manure that can be carried on land. The barley evidently proved its excellence; a ridge of ſummer cucumbers in his garden pointed out to many its great power, the leaves being in general from ten, to ten and a half inches broad, and the vines occupied an uncommon ſpace of ground. Five hundred cabbages and ſavoys, planted by the ſide of four thouſand more, and which had only one handful of the oil manure put in each hole made by the dibble at the time of planting, were evidently near as big again as the others. See Oil-*Compoſt*.

Oil-*Cake*, the cake which remains after the oil has been expreſſed from flax, rape, and ſome other ſorts of ſeeds. Cakes of the firſt ſort are found to be extremely beneficial in the fattening of cattle, ſheep, and other animals, in different

diſtricts, where they are made uſe of upon an extenſive ſcale.

A recent writer has ſtated, that the late advances in the price of this article, have probably rendered it incapable of being made uſe of with much profit, except in particular caſes, and where manure is a principal object: with this ſort of food it is the common practice to give ſome other ſort of meat, ſuch as hay, cut chaff, and other ſubſtances of the ſame nature, and ſome begin by giving to a beaſt of a hundred ſtones, two cakes *per* day of about ſix pounds each, for ſix or eight weeks, and then increaſe them to three, till the animals become fat: at firſt, however, as the animals ſeldom like it, much leſs may be found ſufficient. In addition to the cake, from half a ſtone to a ſtone of hay is given each day, the whole conſumption in cake being about 21 cwt., and in hay 26 cwt., which at the prices previous to the late advance on theſe articles, rendered the expence of winter-fattening an animal of the above ſize ſomething more than ſeven guineas: lean cattle of the ſmaller kinds have been made perfectly fat in the courſe of eight or ten weeks by this ſubſtance in the trials of Mr. Moody. The cake in this application is broken down into ſmall parts, and frequently blended with the chaff or other ſubſtances that are made uſe of with it. On the continent, Mr. Young ſays, linſeed cake is ſometimes exhibited in a liquid ſtate, being diffuſed in hot water, and drank by the cattle, hay and other ſubſtances being given at the ſame time. And in the Lincolnſhire report, a method is ſuggeſted of giving cake to cattle while in the paſtures in a ſmall proportion, with great ſucceſs, a practice which may be applicable, where the cake-fed beaſts are not fully fattened for ſale in the early ſpring months. It is an advantage in fattening with this and other ſimilar ſubſtances, that the animals may be completed with them at much more advanced ages than in other modes of fattening.

But wherever this expenſive ſort of food is employed, great care ſhould be taken that the cakes be freſh, good, and free from mouldineſs. They are the beſt where the expreſſion of the oil has not been carried too far, but where this has happened they are moſtly deficient in nouriſhment.

It has been ſtated by Mr. Donaldſon, that in Lancaſhire, Yorkſhire, Norfolk, and a few other diſtricts, they ſometimes uſe oil-cakes of the latter kind, after being reduced to powder by means of a machine contrived for the purpoſe, as a manure, ſometimes for wheat and barley crops, but more generally for turnips. It is always ſown by hand, and harrowed in with the ſeed. The quantity uſed is from three to ſix quarters the acre. The price is extremely different in different diſtricts. It was then in Lancaſhire from ſix to eight ſhillings the quarter, in ſome parts of Yorkſhire from ſixteen to twenty. Experience has proved, that the ſucceſs of this manure depends in a great meaſure on the following ſeaſon. If rain happens to fall ſoon after the rape-duſt is applied, the crop is generally abundant, but if no rain fall for a conſiderable period, the effects of this manure are little diſcernible either on the immediate crop, or on thoſe which ſucceed it on the land in the following year.

And in an experiment ſtated in the eleventh volume of the Agricultural Magazine, four ridges, about twenty yards wide each, in the middle of a large field, were alternately manured with lime and rape-ſeed cake. The quantity of lime was, it is ſuppoſed, three chaldrons to an acre. The part oil-caked had a quarter of a ton an acre drilled by a machine, which throws the oil-cake reduced to powder, and the turnip ſeed, into the ſame drills. The ſoil was a ſtrong dry red loam, with a few ſpots of gravel interſperſed in different parts of the field. On theſe gravelly ſpots the turnips were rather ſuperior on the parts which were limed; but on the loam the oil-caked ridges produced, at leaſt, double the weight of thoſe which were limed.

Mr. Calvert, at Albury, when oil-cake was much cheaper than at preſent, found it the moſt advantageous and profitable food that he could give his cows; three cakes a day, with eight or ten pounds of hay, or four cakes and good ſtraw, were the uſual allowance; two were given to cows in calf and growing heifers: he practiſed this till cake advanced beyond 9*l.* a thouſand. How far it may anſwer at much higher prices, hay and butter having both greatly advanced, careful experiments will alone aſcertain, which he himſelf ſhould have made, but, Swediſh turnips being introduced and anſwering uncommonly well, he loſt the inducement to go on with the other food. Cake gave very good butter, and at 6*l.* or 7*l.* a thouſand was the cheapeſt food that could be given. Hertfordſhire Agricultural Report.

Good potatoe crops have been raiſed by it in ſome parts of Lancaſhire.

Oil-*Compoſt*, a ſubſtance of the manure kind, prepared by incorporating different oily materials with thoſe of other kinds. It has been highly extolled by ſome cultivators, while others have thought leſs favourably of its properties. It is probable, however, that the expence of articles of this nature muſt render their uſe very limited in moſt ſituations.

But on the ſuppoſition that oil rendered miſcible with water, conſtitutes the chief nouriſhment of vegetables, and affords their principal ſupport; Dr. Hunter of York propoſed the following oil-compoſt.

	£.	s.	d.
Take North American pot-aſh 12lb.	0	4	0
Break the ſalt into ſmall pieces, and put it into a convenient veſſel with four gallons of water. Let the mixture ſtand forty-eight hours, then add coarſe train-oil, 14 gallons	0	14	0
	0	18	0

It may be noticed, that in a few days the ſalt will be diſſolved, and the mixture, upon ſtirring, become nearly uniform. Then take fourteen buſhels of ſand, or twenty of dry mould. Upon theſe pour the above liquid ingredients. Turn this compoſition frequently over, after adding to it as much freſh horſe-dung as will bring on heat and fermentation: in ſix months it will be fit for uſe. And it is apprehended, that the above quantity will be found ſufficient for an acre; his trials, however, do not give him ſufficient authority to determine upon this point. But for the convenience of carriage, he has directed no more earth to be uſed than will effectually take up the liquid ingredients. However, if the farmer chooſes to mix up the compoſt with the mould of his field, he would adviſe him to uſe a larger portion of earth, as he will thereby be enabled to diſtribute it with more regularity upon the ſurface. He has not yet had any extenſive trial of its efficacy upon paſture and meadow grounds; but he preſumes, that whatever will nouriſh corn, will alſo feed the roots of graſs. When uſed upon ſuch lands, it ſhould be put on during a rainy ſeaſon, as all top-dreſſings are injured by the ſolar heat, and all kinds of cattle muſt be kept off the lands for ſome time, as they will bite the graſs too cloſe in queſt of the ſalt contained in the compoſt, which he has found to be the caſe in ſmall trials.

It is added, that the oil-compoſt is only intended to ſupply the place of rape-duſt, ſoot, woollen rags, and other expenſive

expenſive hand-dreſſings. It is in all reſpects inferior to rotten dung: where that can be obtained, every kind of manure muſt give place to it. But at the ſame time that dung affords nouriſhment, it opens the pores of the earth. Hand-dreſſings, on the contrary, give food to plants, but contribute little towards looſening the ſoil. This is an uſeful and practical diſtinction, and may be applied through all the variety of manures made uſe of by the farmer. And it is preſumed, that the oil-compoſt reſembles the natural food of plants; but he ſubmits that, as well as every thing elſe, to experience our unerring guide. It may be objected, that it has not ſufficiently undergone the putrid ferment, to attenuate the oily particles. The uſe of rape-duſt, ſoot, horn ſhavings, and woollen rags, takes off that objection, and at the ſame time confirms the theory upon which the above compoſt is founded. But he does not take upon him to direct the experienced farmer in the manner of uſing this new compoſt. He would have every perſon apply it in the way moſt agreeable to himſelf. Many things will occur to the practical huſbandman, that no reaſoning of the philoſopher could foreſee. By attending to the different ways of uſing it, we may, it is ſuppoſed, reap conſiderable advantages. Improvements may be collected even from the higheſt degree of miſmanagement. And facts muſt ever be the foundation of our reaſoning. Without them, the philoſopher is a kind of *ignis fatuus*. Inſtead of unfolding nature, he covers her with a cloud, and endeavours, as it were, to bring old chaos back again into the world. If, however, he ſhould preſume to inſtruct the farmer in the management of the compoſt, he would recommend it to be ſown immediately after the grain, and both harrowed in together.

The following experiment is ſtated, which, though trifling in its own nature, gave him the firſt encouragement to proſecute the ſubject upon a larger ſcale. He took four pots, Nos. 1, 2, 3, 4.

"No. 1. contained 12lb. of barren ſand, with 1 oz. of the ſand oil-compoſt.

"No. 2. contained 12lb. of ſand without any mixture.

"No. 3. contained 12lb. of ſand, with ½ oz. of ſlaked lime.

"No. 4. contained 12lb. of ſand, with 4 oz. of the ſand oil-compoſt."

And in the month of March he put ſix grains of wheat into each pot, and during the ſummer occaſionally watered the plants with filtered water. All the time that the plants were conſuming the farina, he could obſerve but little difference in their appearance. But after one month's growth, he remarked that No. 1. was the beſt; No. 2. the next; No. 3. the next; No. 4. much the worſt. And in Auguſt he made the following obſervations: No. 1. had five ſmall ears, which contained a few poor grains. No. 2. had three ſmall ears, containing a few grains, much inferior in goodneſs to the former. No. 3. had no ears. Only he obſerved two very ſmall ones within their reſpective ſheaths, which for want of vegetable ſtrength never made their appearance. No. 4. had no ears; the ſtalks appeared ſtunted in their growth.

"He then removed the plants from their pots, and took a view of the roots of each.

"No. 1. The roots tolerably large, and well ſpread.

"No. 2. The roots not ſo large.

"No. 3. The roots very ſhort and ſmall.

"No. 4. The roots much the ſhorteſt, with the appearance of being ricketty."

Upon this experiment it is ſuggeſted,

"1. That the oil-compoſt may be conſidered as a vegetable food; but it, when uſed too liberally, the alkaline ſalt will burn up the roots of the plant, and hinder vegetation. For which reaſon he would recommend the compoſt to be expoſed to the influence of the air for ſome months, before it is laid on. 2. That lime contains no vegetable food, and is, in its own nature, an enemy to vegetation. It is, however, of excellent uſe in aſſiſting vegetation."

Theſe experiments teach him, that all kinds of ſoils may be benefited by this manure. The limeſtone, gravelly, ſandy, and chalky ſoils ſeem to require it moſt. The rich loams and good clays have nouriſhment within themſelves, and ſtand more in need of the plough than the dung-hill. And it is noticed, that it is obſerved by farmers, that rape-duſt ſeldom ſucceeds with ſpring-corn, unleſs plentiful rains fall within a few weeks after ſowing. He has more than once made the ſame obſervation upon the oil-compoſt, which induces him to recommend it for winter crops only. From the unctuouſneſs of its nature, it is more than probable, that it ſhould lie expoſed for a long time to the influence of the weather, which benefit it is deprived of when uſed for barley, and ſuch crops as are ſown late in the ſpring. He is confirmed in this idea, from repeated experiments made with the compoſt upon turnips, which generally proved unſucceſsful. And at the ſame time he invariably found that thoſe parts of the field on which the compoſt had been ſpread produced the beſt crops of grain the following year. From this ſlow manner of giving its virtues, it ſeems to be an improper dreſſing for all plants that have a quick vegetation.

On the whole it is concluded, that the oil-compoſt, as it plentifully reſtores particles of the oily kind, ſimilar to thoſe that are carried off, has a fair appearance of proving an excellent reſtorative.

The following experiments in ſupport of the utility of this ſort of manure are ſtated. In the month of June he ſelected four lands of equal goodneſs in a field intended for turnips. The ſoil was a light ſand, with a ſmall portion of vegetable earth amongſt it. It was ploughed out of ſward in November, and had not borne a crop for many years. He diſtinguiſhed his experimental lands by Nos. 1, 2, 3, 4.

No. 1. was manured with rotten dung.

No. 2. with oil-compoſt.

No. 3. with lime.

No. 4. was left without any dreſſing.

On the 20th of June they were all ſown with turnip-ſeed, broadcaſt, and during the courſe of the ſeaſon were twice hoed.

"In November he viewed the field, and made the following remarks:

N° 1—the beſt.

2—the next.

3—the worſt.

4—better than N° 3.

"Here he ſuppoſes the oil-compoſt appears in a favourable light; but other trials, made with equal accuracy, ſeem rather to prove that it is not proper for turnips, barley, or quick growing vegetables. It requires being meliorated by the action of the atmoſphere, and therefore is better adapted to winter crops." But by repeated experiments made ſince he firſt brought forward this manure, he is "convinced that the addition of an alkaline ſalt is not ſufficient to alter the nature of ſoil, ſo as to make it fully capable of entering in to the roots of plants in its native form: but when decompoſed by the mixture of freſh dung, he is convinced that it then becomes the true pabulum of plants."

It is ſuppoſed that "when the land happens to be ſtiffer than is required for turnips, it may be good huſbandry to lay upon it a large quantity of lime to open its body for the free admiſſion of the tap-root of the turnip. The lands will

alſo be rendered more dry, without which the turnips will never arrive at any ſize. Farmers, in general, take great pains to pulverize their light ſoils intended for turnips; but they ſeldom plough deep enough. A turnip is found to root deep, and in all operations of huſbandry we ſhould be careful to follow the bias of nature. It is for that reaſon we ought to make ourſelves acquainted with the ſize and the ſhape of the roots of ſuch plants as are the objects of field huſbandry: when once we have obtained that neceſſary knowledge, it will be an eaſy matter to ſuit the preparation of the ſoil to the nature of the grain. It will alſo enable us to direct the variations of our crops upon juſt and rational principles."

But in Mr. Stovin's trials with oil-compoſt in 1769, the reſults were theſe:

	£	s.	d.	Produce. Q.	B.	P.
"One acre, ſown with barley, and manured with oil-compoſt -	0	18	0	5	5	0
"One acre adjoining, ſown with barley, and manured with rotten dung, twelve loads, worth -	3	0	0	4	3	2
Difference	1	1	2			

And the compoſt barley was bolder and better corn than the other. In the year 1770, the dunged acre produced of rye, three quarters. The compoſt acre, of ditto, two quarters ſix buſhels. And in the year 1771, the ſame lands were ſown with oats, and the produce was greatly in favour of the dunged acre. This laſt experiment, being contrary to the idea of good huſbandry, was made with a view to determine the abſolute ſtrength of the compoſt. All top-dreſſings are exhauſted in the year. The oil-compoſt ſeems to retain its vigour longer. It will here be proper to obſerve, that theſe experimental lands were in a common field, which had been many years under the plough.

Alſo in Mr. Townley's experiments, they were as below. "In the ſpring of 1770, he prepared a piece of ground for onions. It was laid out into ſix beds of equal ſize, and all ſown at the ſame time.

"Over two of them, the oil-compoſt was ſcattered in a very moderate quantity; over the other two, pigeon-dung; and over the remaining two, ſome of his weed-compoſt, which he eſteems one of the beſt manures, for moſt vegetables, that can be made." It is compoſed of vegetable ſubſtances reduced into a putrid ſtate. "The onions came up very well in all the beds; but, in about ſix weeks, thoſe that were fed with the oil-compoſt plainly diſtinguiſhed the advantage they had over the reſt, by their luxuriancy and colour; and at the end of the ſummer perfected the fineſt crop that he had ever ſeen, being greatly ſuperior to the others both in quantity and ſize."

In another experiment with it in this crop, his ſucceſs was ſtill much greater though the ſoil was worn out. The oil-compoſt was uſed as a top-dreſſing after the crop was ſown. "The ſame ſpring he made an experiment upon four rows of cabbages, ſet at the diſtance of four feet every way. Two were manured with the oil-compoſt, and two with his own. All the plants were unluckily damaged, juſt before they began to form, by ſome turkies getting into the field, and plucking off the greateſt part of the leaves. However, they ſo far recovered as to weigh, in the September following, from 22lbs. to 28lbs. a-piece. The rows proved ſo equal in goodneſs that he could not determine which had the advantage."

And "the ſame year one part of a field of wheat expoſed to the north-eaſt winds, which that ſpring continued to blow for a month or five weeks, appeared very poor and languid at the time of tillering. Over it he ordered ſome of the oil-compoſt to be ſown with the hand, which not only recovered, but alſo puſhed forwards the wheat plants in that part of the field, ſo as to make them little inferior, if any, to the reſt."

The ſame ſpring he "made a comparative experiment upon four contiguous lands of oats, between the oil-compoſt and his own weed-compoſt. The latter had manifeſtly the advantage, though the other produced a very fine and large crop. He alſo tried the oil-compoſt upon carrots, and it anſwered exceedingly well. He did the ſame this year (1771), both upon them and his onions; and has the fineſt crops of thoſe vegetables he ever ſaw any where upon the ſame compaſs of ground."

Mr. Roebuck, in trying this manure in gardening, planted twelve alleys, that lay between his aſparagus beds, with cauliflower plants; each alley took up about thirty plants. One of the alleys he ſet apart for an experiment with the oil-compoſt, prepared as above.

"About a handful of the compoſt was put to the root of each cauliflower plant. In all other reſpects the alley was managed like the reſt. The plants in general flowered very well; but thoſe to which he applied the compoſt, ſprung up haſtily with ſmall ſtalks, and produced very poor flowers. He imputed this unfavourable appearance to the freſhneſs of the compoſt, which was only a few weeks old. In all future trials, he intends to expoſe it to the action of the air, in order to abate the heat, and neutraliſe the acrimony of the ſalt."

But "in the September following this unſucceſsful experiment, he planted the ſame alleys with early cabbages. The neceſſity of melióràting the compoſt was in this trial fully confirmed. For the cabbages that grew upon the alley, which in May had received the compoſt, were larger, and in all reſpects finer, than the others. The idea that he entertains of the compoſt is, that when meliorated in the earth, it is capable of giving a richneſs and freſhneſs to it. Upon this principle he would recommend it to gardeners as a ſubject worthy of further trials.

Although theſe experiments ſufficiently ſhew, that ſubſtances of this ſort may be uſed with advantage in the way of manures, their expence muſt in moſt caſes prevent their being made uſe of to any great extent.

Oil-*Manure*, ſuch as is conſtituted of oil with other materials. The compoſition of a manure of this kind, which has been ſaid to be highly beneficial, with the expence for one acre of land in 1792, is thus ſtated:

	£	s.	d.
Rape or train-oil ſix gallons, at 2*s.* 6*d.* -	0	15	0
Sea-ſand ſix buſhels, at 2*d.* - -	0	1	0
Coarſe ſalt two buſhels, at 1*s.* - -	0	2	0
Malt coombs 24 buſhels, at 4½*d.* - -	0	9	0
	1	7	0

In the preparation of which, it is adviſed to ſpread the coombs on the floor about four inches thick, then to ſprinkle the ſalt as level as poſſible, throwing on half the quantity of ſand and half the quantity of oil out of a watering-pot, turning it and raking it well, afterwards to add the reſt of the oil and ſand as before, turning it well till thoroughly mixed, and then throw the whole into a heap for uſe. On this it is ſuggeſted, that as the prolific quality of oil-cake is only in proportion to the oil it contains, this compoſition muſt be preferable, having a much greater quantity of oil

in

in it; and as malt coombs are a manure of themſelves, eſpecially for turnip land, at about eighty or ninety buſhels *per* acre, he dares venture to aſſert, that twenty-four buſhels with the addition of oil is equal to the above quantity, or even to the twelve loads of muck. The ſand and ſalt mixed with it, not only occaſion it to imbibe the oil more freely, but likewiſe give it a better body for the conveniency of ſpreading on the land. And though ſome may think the quantity of ſalt is too little, he is convinced of the contrary, having found by experience that a ton or even a ton and a half has not anſwered ſo well as three or four hundred. The caſe is very ſimilar with regard to lands near the ſalt marſhes, where the tide ſometimes overflows them, and it is well known by thoſe who occupy ſuch lands that nothing will grow for three or four years, but afterwards they become very fertile. The reaſon he ſhall not take upon himſelf to give, but he has found it ſo by his own experience. The writer concludes by obſerving, that ſome farmers have uſed only half the above quantity *per* acre, notwithſtanding which they had good crops. But it has been obſerved that the extra expence makes againſt its becoming generally uſeful from the great price of oil, and the expence of the carriage of ſea ſand and droſs ſalt, in moſt inland ſituations. See OIL-*Compoſt*.

OIL-*Paint*, in *Rural Economy*, that ſort of paint which is compoſed of oil, and the oxyd of lead, or ſome other ſimilar ſubſtance, to form its baſis, or give it a body, and which is uſed for various farm purpoſes.

But the great expence of paints of this ſort has led lately to the introduction of many other materials, for the protection of wood work, and boarding of different kinds, ſuch as preparations from foſſil coal, &c. But a great objection to all theſe ſubſtances, beſides their expence, is the highly diſagreeable ſmell that they afford, and their liability to crack and bliſter.

In caſes where oil painting cannot be had recourſe to, either becauſe it does not dry ſoon enough, and has an inſupportable ſmell, or becauſe it is too dear; the following method has been employed by Mr. Ludicke for painting ceilings, gates, doors, and even furniture, with great ſucceſs: it is thus prepared, take freſh curds, and bruiſe the lumps on a grinding-ſtone, or in an earthen pan, or mortar, with a ſpatula. After this put them in a pot with an equal quantity of lime, well quenched, and become thick enough to be kneaded; ſtir this mixture well without adding water, and a white coloured fluid will ſoon be obtained, which may be applied with as much facility as varniſh, and which dries very ſpeedily. It muſt, however, be employed the ſame day, as it will become too thick the next day. And with this ochre, armenian bole, and all colours which hold with lime, may be mixed according to the colour which is wiſhed to be given to the wood; but care muſt be taken that the addition of colour made to the firſt mixture of curds and lime contain very little water, otherwiſe the painting will be leſs durable.

In performing the work, after two coats of this paint have been applied, it may be poliſhed with a piece of woollen cloth, or other proper ſubſtance, and will become as bright as varniſh.

It is aſſerted that this paint, beſides being cheap, has other advantages; in the ſame day two coats may be laid on and poliſhed, as it dries ſpeedily, and has no ſmell. If it be required to give it more durability in places expoſed to moiſture, it may be done after it has been poliſhed with the white of an egg; which is ſaid to render it as durable as the beſt oil painting that can be employed. And another ſubſtitute that may be uſed for painting weather boarding is prepared by taking three parts air-ſlaked lime, two of wood-aſhes, and one of fine ſand or ſea-coal aſhes, ſifting them through a fine ſieve, and then adding as much linſeed oil as will bring it to a conſiſtence for working with a painting bruſh: great care muſt be taken to mix it perfectly. It is impenetrable to water, and the ſun hardens it, and renders it a great preſerver of the wood.

Another compoſition has likewiſe been made uſe of with great benefit to paint boards, &c. which is made in this way. Melt twelve ounces of roſin in an iron pot, adding three gallons of train oil, and three or four rolls of brimſtone; when melted thin, as much Spaniſh brown ochre firſt ground fine with as much of the oil as will give the colour, ſhould be added; it ſhould be laid on with a bruſh as hot and as thin as poſſible, and ſome days after the firſt coat is dry another applied. It will preſerve planks for a very great length of time, as well as other ſubſtances.

The kinds of oils, their properties, manners of expreſſion, &c. are numerous: for the generality of them, the reader is referred to the proper articles.

Such as could not be more conveniently inſerted, are as follow.

OIL *of the Almond*, in the *Materia Medica*, is obtained either from the ſweet or the bitter almond, that from the one or the other being equally free from bitterneſs. The almonds are put into a coarſe hempen or hair ſack, and ſhaken violently, in order to detach, by friction with one another and againſt the ſides of the ſack, the outer-brown ſkin, which is apt to give a bitter taſte to the oil: they are then bruiſed and made into a paſte, and preſſed in the uſual manner. The London college directs the almonds to be macerated in cold water for 12 hours, and then bruiſed; and the oil is afterwards to be expreſſed without heat. The Edinburgh college orders any quantity of almonds to be bruiſed in a ſtone-mortar, and then put into a hempen ſack; the oil is to be expreſſed without heat. The Dublin college prepares this oil by bruiſing the freſh almonds in a mortar, and expreſſing it by a preſs, without heat. Sixteen ounces of almonds yield about five ounces of a bland inodorous oil, of a very ſlightly ſweetiſh taſte, which is at firſt turbid, but ſoon becomes clear. About ʒiii more may be obtained by impregnating the marc with the ſteam of boiling water. The colour of this oil is very pale greeniſh-yellow, and its ſpecific gravity .932, Fabroni; .917, Aikin. The degree at which it congeals is variouſly ſtated at 19° Fahr. and 8° Fahr. It is ſaid that the oil from the bitter almond keeps longer without growing rancid than that from the ſweet almond. This oil is demulcent and emollient, and uſed in coughs and other pulmonary complaints united with water by means of mucilage, or the yolk of egg and ſugar. A mixture of f.ʒiv of almond oil, ♏ viii of acetate of lead, forms an uſeful injection at the commencement of gonorrhœa. The doſe of the oil is from f.ʒiv to f ʒj. See ALMOND.

OIL *of Amber* of the London college is obtained by putting the amber into an alembic, and diſtilling from a ſand-bath, with a fire gradually raiſed, an acid liquor, the oil, and a ſalt impregnated with the oil; then re-diſtilling the oil twice.

The *purified* oil of amber of the Edinb. diſpenſatory is had by diſtilling oil of amber, mixed with ſix times its weight of water, from a glaſs retort, until two-thirds of the water have paſſed into the receiver; then ſeparating this purified volatile oil from the water, and keeping it in well ſtopped veſſels.

The *rectified* oil of amber of the Dublin pharmacopeia is prepared by taking a pound of the oil which comes over in the preparation of ſuccinic acid, and ſix pints of water, and diſtilling

diſtilling until two-thirds of the water have paſſed into the receiver, and ſeparating the oil. This oil is of a dark colour, thick conſiſtence, and fœtid odour; but by ſucceſſive diſtillations, it is rendered thinner, of a lighter colour, and at length nearly limpid. Rectified oil of amber has a ſtrong ungrateful odour, and a hot acrid taſte. It is light, volatile, and inflammable, inſoluble in water, and only partially ſoluble in alcohol. As to its medical properties, it is ſtimulant, antiſpaſmodic, and rubefacient. It has been found ſerviceable in deficient menſtruation, and in hyſteria, epilepſy, and ſome other convulſive affections; but it is now ſcarcely ever uſed as an internal remedy. The doſe may be from ♏ v to ♏ xij, combined by means of mucilage with any diſtilled water. It is more generally employed as a rubefacient in rheumatiſm and paralyſis; and a mixture of f.ʒj of this oil with f.ʒſs of tincture of opium, has been found beneficial as a friction to the affected part in tic douloureux; and in hooping-cough, rubbed upon the cheſt two or three times a day. The officinal preparation is the Spiritus *Ammoniæ Succinatus* of the London college. See Amber and Succinic *Acid*.

Oils, *Animal*, in general, are thoſe that are obtained from animal ſubſtances, either in the ſtate of butter and fat, uncombined with the other principles of animal matters; of which kind are fat, marrow, the expreſſed oils of yolks of eggs, ſpermaceti, &c. Or, in a ſtate of combination, afforded by diſtillation of the gelatinous ſubſtance, which forms almoſt entirely all the parts compoſing animal bodies, as fleſh, tendons, nerves, cartilages, bones, horns, hair, &c. See Oil, *ſupra*.

Oil, *Animal*, *Oleum Animale*, in a more reſtricted ſenſe, the name of an eſſential oil diſtilled by a retort from blood, and formerly recommended as a powerful internal remedy in epilepſies, the gout, and other obſtinate diſeaſes.

It was originally uſed in Germany in theſe intentions. As an external, it may probably be of good ſervice in removing fixed pains, hard tumours, &c. for it is extremely penetrating.

Oil, *Volatile*, *Animal*, or *Dippel's oil*. (See Dippel's *Oil*.) If albumen or gluten be diſtilled at a dry heat, there ariſes, together with the ammonia and carburetted hydrogen, a quantity of fœtid black oil, which was the ſubject of various experiments, firſt by Dippel, a chemiſt of Berlin, and afterwards by Rouelle. From the concurrent labours of the enquirers, it appears that if this oil is rectified by three ſucceſſive diſtillations from the ſurface of water, it becomes at length quite colourleſs and tranſparent; its odour is powerful, but ſomewhat aromatic, and it is nearly as light and volatile as ether. It contains a little ammonia, and hence changes the colour of ſyrup of violets green; it is ſparingly ſoluble in water, and largely ſo in oils, ether, and alcohols. It combines both with acids and alkalies into imperfect ſoaps; it is very inflammable, and, like the vegetable eſſential oils, may be ſet on fire by ſtrong nitrous acid. If expoſed even to the light, it is partly decompoſed, loſing its tranſparency, and becoming of a brown colour. It was formerly employed in medicine; but is now wholly diſuſed. Aikin's Dict.

Oil *of Aniſe-ſeed*. (See Anise-seed.) This oil is given as a carminative, and for relieving flatulence in children, from ♏ v to ♏ xv triturated with ſugar. The officinal preparations are tinctura opii ammoniata of the Edinburgh college, and tinctura opii camphorata of the Dublin college. See Tincture.

Oil *of Antimony*, a name given to the butter of antimony, and ſome other ſolutions of antimony by acids. See Antimony.

Oil *of Arſenic*. See Arsenic.

Oil *of Aſpic*, or *Spike*. See Spike.

Oil *of Balm*. See Balsam and Melissa.

Oil *of Bays* is an eſſential oil, obtained from the berries of the bay, or Laurus *Nobilis*. Theſe berries give out to the preſs an almoſt inſipid fluid oil; and on being boiled in water, a thicker butyraceous one, of a yellowiſh-green colour, impregnated with the flavour of the berry. The berries and leaves of the bay are accounted ſtomachic, carminative, and uterine: with this view, infuſions of the leaves are drank as tea, and the eſſential oil of the berries is given on ſugar, or diſſolved by means of mucilages, or in ſpirit of wine, from one to five or ſix drops. But the principal uſe of theſe ſimples in the preſent practice is external: they are made ingredients in carminative glyſters, warm cataplaſms, and uterine baths; and the butyraceous oil of the berries ſerves as a baſis for ſome nervine liniments, and mercurial and ſulphureous unguents. Lewis. See Daphneleæon.

Oil *of Beech*, See Beech-*oil*.

Oil *of Been*, or *Ben*. See Ben.

Oil, *Birch*, a vegetable empyreumatic oil, prepared in Ruſſia, by charring birch-wood in a cloſe oven, the watery acid and oil being collected in a large receiver; and the latter product being the lighteſt, is ſkimmed off from the ſurface of the water. This oil has a peculiar ſcent, and is ſaid to drive away worms and other inſects; on which account it is uſed in the dreſſing of Ruſſia leather, to which it communicates thoſe properties that render it ſo much eſteemed by the binders of books.

Oil, *Britiſh*, an empirical medicine of the ſame nature with the petrolea; the genuine ſort being extracted by diſtillation from a hard bitumen, or a kind of ſtone-coal, found in Shropſhire, and other parts of England. Lewis.

Oil, or *Butter*, of *Cacao*. See Cocos.

Oil, *Cajeput*. See Cajeput and Melaleuca.

Oil *of Camphor*. See Camphor and Laurus.

Oil *of Caraway*. (See Carua.) Six pounds of caraway-ſeeds yield 4½ ounces of oil, which has an aromatic odour, and a ſweetiſh pungent taſte; it is viſcid, and of a yellow colour; its ſpecific gravity is .946. This oil, which is ſtimulant and carminative, is chiefly uſed as an adjunct to purgative pills, and for covering the diſagreeable flavour of other ſubſtances. The doſe is from ♏ j to ♏ x. The officinal preparations are electuarium ſennæ, confectio ſcammonii, pilulæ aloes comp., and pilulæ aloes, cum myrrha.

Oil *of Caſtor*. See Castor and Ricinus.

Oil, *Cardamom*. See Cardamom.

Oil, *Cauſtic*. See Arsenic.

Oil *of Chamomile*, an oil diſtilled from anthemis or chamomile. Its odour is unpleaſant, and its taſte pungent. When recently diſtilled, its colour is a cerulean blue, which changes by age to a deep yellow. Eighty-two pounds of chamomile-flowers yield 18 drams of oil. This oil is ſuppoſed to poſſeſs antiſpaſmodic powers, and is therefore ſometimes recommended in cramp of the ſtomach, and as an adjunct to purgative pills. The doſe is from ♏ v to ♏ x, but it is ſeldom uſed. See Anthemis.

Oil *of Cinnamon*. See Cinnamon.

Oil *of Cloves*. See Caryophyllus.

Oil *of Cole-Seed*. See Cole-*Seed*.

This oil, and alſo thoſe of muſtard-ſeed, rape-ſeed, and ſunflower-ſeed, are leſs coloured and leſs highly flavoured than thoſe of linſeed and hemp-ſeed. They are very little liable to dry by expoſure to the air; and theſe circumſtances, together with their moderate price, induce a large conſumption of them by the wool-dreſſers, in order to preſerve

ſerve the wool from the attacks of moths and other inſects; and alſo by the leather-dreſſers.

Oil, *Connecting*, a term uſed by Boerhaave, and his followers, to expreſs a certain oil, found in all vegetable ſubſtances, but wholly different from, and independent of, their eſſential oil. This is not poſſeſſed of any of their virtues or qualities, but ſeems the ſame in all plants, and is the means of their conſiſtence and ſolidity, giving tenacity to their earth, which, without it, falls to duſt, and the plant exiſts no more.

This oil is not ſeparable by boiling water, as the eſſential oil is, but only by fire: when a plant has been boiled and diſtilled, its eſſential oil, ſalt, &c. are all carried off, and what remains is only the earth corrected by this oil. This being expoſed to the fire, the oil diſcovers itſelf in a thick, black, ſtinking ſmoak, and, finally, taking fire, it burns away, and leaves only the earth, which was the baſis of the plant; retaining its form, indeed, if the proceſs has been carefully made, but falling into a ſhapeleſs powder only on being roughly breathed upon.

This great author, therefore, eſtabliſhes it as a rule, that there are three ſorts of oil in plants. 1. An oily froth. 2. The eſſential oil, diſſolved in decoction. And, 3. This connecting, or conſolidating oil, ſeparable only by a naked fire.

Oil, *Cornel*, a fixed oil reſembling olive oil, by being contained, not in the ſeed, but in the pulpy fruit of the vegetable. The berries of this ſhrub (Cornus *Sanguinea*) being collected when quite ripe, and laid in heaps for a few days to mellow, are to be reduced to a pulp, and preſſed without heat in the uſual manner. By this treatment, from 22lbs. avoirdupois may be obtained ſomewhat more than four wine pints of a fat, ſomewhat viſcid, oil, of a bright green colour, and equally deſtitute of any unpleaſant flavour as the beſt olive oil. When heated with nitric acid, it is converted to a brown-yellow butter or wax. By boiling with litharge, it becomes drying; when ſpread thin on water, and expoſed to the air for a month, it is converted into a white wax. It does not freeze ſo readily as olive oil, and laſts rather longer than this when uſed in a lamp. Aikin's Dict.

Oil *of Cumin*. See Cuminum.

Oil *of Dill*. See Anethum.

Oils, *Drying*. See Oil, *ſupra*.

Drying oils are formed of linſeed oil, prepared by means of boiling, ſometimes with and ſometimes without the addition of other ſubſtances. Thoſe commonly added to oil, in this preparation, are white vitriol, ſugar of lead, ſeed-lac, gum maſtic, gum ſandarac, gum anime, gum copal, umbre, colcothar, litharge, and red-lead. A drying oil for the nicer works may be prepared by boiling two ounces of gum ſandarac, white vitriol, and ſugar of lead, of each one ounce, in a pint of nut or poppy oil, till the ſolid ingredients be diſſolved, and the mixture becomes of the colour of linſeed oil. For coarſer work, take one gallon of linſeed oil, one pound of litharge of gold or ſilver, half a pound of white vitriol, and ſugar of lead, gum arabic, and umbre, of each a quarter of a pound; boil them as long as the diſcolouring of the oil, which is the gradual conſequence of boiling, will allow. That made for ſale is prepared by boiling one gallon of linſeed oil, and one pound and a half of red-lead, as long as the colour will bear it. When the calxes of lead are united in ſmall quantity with oil, they diminiſh its fluidity, and diſpoſe it to dry more readily. Theſe oils are much uſed in painting, on account of their drying quality. When a large quantity of calxes of lead is combined with oil, they form with it a ſolid, opaque, and tenacious body, capable of ſoftening by heat. Theſe combinations are uſeful in pharmacy, for giving a convenient conſiſtence and tenacity to many plaſters.

Oils, *Diſtilled*, are the volatile oils, ſo called in the London pharmacopeia. For preparing them, they direct that the ſeeds of aniſe and caraway the flowers of chamomile and lavender, the berries of juniper and all-ſpice, the tops of roſemary, and the entire plants of the other articles, dried, are to be employed. Any one of theſe is put into an alembic, and as much water poured in as will cover it; and then the oil is diſtilled into a large refrigeratory. The water which diſtils over with the oils of pepper-mint, ſpear-mint, all-ſpice, and penny-royal, is to be preſerved for uſe.

Oil *of the Earth*, *Oleum Terræ*, in the *Materia Medica*, the name of a thick mineral fluid of a duſky browniſh-black, with a faint caſt of purple, and of the conſiſtence of a thin ſyrup, very little tranſparent, and of a ſtrong penetrating ſmell, like that of common oil of amber. It oozes out of the cracks of rocks, in ſeveral parts of the iſland of Sumatra, and ſome other parts of the Eaſt Indies, and is much eſteemed there in paralytic diſorders; but it is ſeldom imported into England; what our Eaſt India ſurgeons and captains uſually bring over under this name being only a vegetable oil, impregnated with the virtues of certain of their foſſils by boiling. See Petrol.

Oil, *Empyreumatic*. See Oil, *ſupra*, and Empyreuma.

Oils, *Eſſential*, are thoſe which have evidently the ſmell of the vegetable from which they are obtained. All theſe oils are ſufficiently volatile to riſe with the heat of boiling water; and this degree of volatility is one of their ſpecific characters. See Oil, *ſupra*.

The oils of plants have not always the ſame taſtes with the plant they are diſtilled from, or, at leaſt, not in the ſame degree. Nothing is more bitter than wormwood, yet the oil of wormwood has no remarkable bitterneſs. Aniſe, which is of a ſweet taſte, yields, on the contrary, an oil infinitely more ſweet than the ſeed; and pepper, which is ſo remarkably hot and acrid, affords an oil no way remarkable for its pungency. Thyme, which is in itſelf very acrid and pungent, conveys that property, in a yet greater degree, to its oil; there is, indeed, no eſſential oil ſo acrid and fiery as that of this plant. The fetid oils drawn in dry diſtillation by the retort, in an open fire, no way differ from theſe but by the damage the fire has done them, and may always be converted into theſe by repeated diſtillations. Nay, the very fat oils, ſuch as that of almonds, may be attenuated ſo far as to become as fine, and as ſubtile, as the eſſential oils. This is to be done by means of quick-lime; and ſeveral repeated diſtillations of this oil, or any other of a like kind, with freſh lime to every diſtillation, will reduce it to be volatile, penetrating, and capable of being raiſed, and diſtilled, by means of water, which is the greateſt teſt of the eſſential oils. The bituminous and fetid oils may alſo, in the ſame manner, be reduced, by repeated diſtillations, to the ſtate of the eſſential ones, and to be equally fluid and limpid, and equally penetrating. Memoirs Acad. Par. 1721.

The eſſential oils of vegetables may be divided into two claſſes, according to their different ſpecific gravities, ſome floating upon water, and others readily ſinking to the bottom thereof. Thus the eſſential oils of cloves, cinnamon, and ſaſſafras, readily ſink; but the oils of lavender, marjoram, mint, &c. ſwim upon the water. The lighteſt of all the eſſential oils is, perhaps, that of citron peels, which even floats on ſpirit of wine; and the heavieſt of them ſeems to be the oil of ſaſſafras.

For the obtaining the full quantity of the more ponderous oils

oils from cinnamon, cloves, ſaſſafras, &c. it is proper 1. To reduce the ſubjects to fine powder. 2. To digeſt this powder for ſome days in a warm place, with thrice its quantity of ſoft river water, made very ſaline with the addition of ſea-ſalt, or ſharp with oil of vitriol. 3. To uſe the decoction left in the ſtill, inſtead of common water, for a freſh digeſtion. 4. To uſe alſo, for the ſame purpoſe, the water of the ſecond running, after it has been cleared of its oil. 5. Not to diſtil from too large a quantity of the ſubject at once. 6. To leave a conſiderable part of the ſtill empty. 7. To uſe a briſk fire, or a ſtrong boiling heat at firſt, but to ſlacken it a little afterwards. 8. To have a low ſtill head, with a proper internal lodge, and current, leading to the noſe of the worm. And, 9. To cohobate the water, or pour it back upon the matter in the ſtill, after ſeparating its oil, and repeating this once or twice more.

The vegetable world affords vaſt variety of eſſential oils, moſt of them very odorous, and of great virtues; but different vegetables yield oils of different conſiſtence, and in different quantities.

Theſe oils are employed in painting, in ſpirituous liquors uſed at the table and at the toilette, in perfumes, and in medicine. As they act very powerfully, ſmall doſes, as from one drop to four or five, incorporated with ſugar, muſt be given internally. They are recommended as cephalic and antiſpaſmodic, in convulſive and hyſterical affections: they are alſo ſtimulant, ſudorific, and ſtrengthening. All drugs which are alexipharmic, cephalic, tonic, and ſtomachic, containing vegetable aromatic, derive their virtues from the eſſential oils of theſe vegetables. The ſame may be ſaid of all medicinal, aromatic, and ſpirituous waters. In ſome caſes, eſſential oils are employed externally as ſtrengtheners, and to allay painful ſpaſms of nervous and tendinous parts, to reſolve and diſſipate acrid humours, which occaſion pain, without any ſenſible inflammation; but they muſt not, on account of their cauſtic quality, be uſed alone, but formed into liniments or pomatums, by mixing them with a ſufficient quantity of fat, or fat oils. When applied to the human body, they ſtimulate, corrode, and reſiſt putrefaction; and mixed with the blood, raiſe ſome degree of fever. Med. Eſſ. Edinb. vol. v. art. 24. See *Volatile* OILS, *infra*.

As many of the eſſential oils are dear, it is a very common practice to adulterate, or debaſe them ſeveral ways, ſo as to render them cheaper both to the ſeller and the buyer. Theſe ſeveral ways ſeem reducible to three general kinds, each of which has its proper method of detection. Theſe three ways are, 1. To adulterate them with expreſſed oils. 2. With alcohol. And, 3. With cheaper eſſential oils.

If any eſſential oil be adulterated with expreſſed oil, it is eaſy to diſcover the fraud by adding a little ſpirit of wine to a few drops of the ſuſpected eſſential oil, and ſhaking them together; for the ſpirit will diſſolve all the oil that is eſſential, or procured by diſtillation, and leave all the expreſſed oil that was mixed with it untouched.

If an eſſential oil be adulterated with alcohol, or rectified ſpirit of wine, it may be done in any proportion, up to that of an equal quantity, without being eaſily diſcoverable either by the ſmell, or taſte. The way to diſcover this fraud is to drop a few drops of the oil into a glaſs of fair water; and if the oil be adulterated with ſpirit, the water will immediately turn milky, and by continuing to ſhake the glaſs, the whole quantity of ſpirit will be abſorbed by the water, and leave the oil pure at top.

Finally, if an eſſential oil be adulterated by a cheaper eſſential oil, this is commonly done very artfully: the method is to put fir-wood, turpentine, or oil of turpentine, into the ſtill, along with the herbs to be diſtilled for their oil, ſuch as roſemary, lavender, origanum, &c.; and, by this means, the oil of turpentine diſtilled from theſe ingredients comes over in great quantity, and is intimately blended with the oil of the genuine ingredient. The oils thus adulterated always diſcover themſelves in time, by their own flavour being overpowered by the turpentine ſmell; but the ready way to detect the fraud is to drench a piece of rag, or paper, in the oil, and hold it before the fire; for thus the grateful flavour of the plant will fly off, and leave the naked turpentine ſcent behind. Shaw's Lectures, p. 145.

The eſſential oils, as volatile oils are called by the Dublin college, are prepared in the following manner: let the oil be extracted by diſtillation from the ſubſtance previouſly macerated in water, as much water being added during the diſtillation as may be ſufficient to prevent empyreuma. In diſtilling fennel, pepper-mint, ſpear-mint, penny-royal, and all-ſpice, the watery fluid that comes over in diſtillation with the oil is to be preſerved for uſe.

OIL *of Fennel Seeds*. (See ANETHUM *Fœniculum*.) Seventy-five pounds of fennel ſeeds yield thirty ounces of oil, which is colourleſs, and congeals at 50°. It has the odour of the plant and a ſweet taſte. The ſpecific gravity is .997. The medical properties and uſe are the ſame with thoſe of the plant. The uſual doſe is from ♏ ij to ♏ xx; but it is rarely uſed.

OIL, *Fern*. See FERN.

OIL, *Granulated*, is that fixed in little grains; this is the beſt, and moſt eſteemed, eſpecially of oils of olives.

OIL, *Green*, *Oleum Viride*, a form of medicine preſcribed in the late London pharmacopeia, and made in the following manner: take leaves of bay, rue, marjoram, ſea-wormwood, and chamomile, each three ounces; oil of olives, a quart. Boil the herbs in the oil till they are criſp, and then ſtrain off the oil; and when it has ſtood for the fæces to ſubſide, put it up for uſe.

OIL *of Hartſhorn, Rectified*, is prepared by the Dublin college in the following manner. Take of the oil which riſes in the diſtillation of the volatile liquor of hartſhorn, three pounds, and ſix pints of water. Diſtil the oil, then remix it with the water, and rediſtil, repeating the diſtillations until the oil becomes limpid. This oil ſhould be kept in a dark place, in ſmall phials completely filled and cloſely ſtopped.

This empyreumatic oil is firſt formed by the decompoſition of animal matter by heat; and ariſes from a new combination of part of the hydrogen and carbon of the ſubſtance diſtilled. When firſt obtained, it is thick, of a dark colour, and has a very offenſive odour; but by the rectification preſcribed, it is rendered thinner and leſs offenſive. The rectified oil is nearly colourleſs and tranſparent; it has a ſtrong, ſlightly aromatic odour, and a penetrating taſte. It is very light and volatile, ſtrikes a green colour with ſyrup of violets, is partially ſoluble in water, and unites readily with alcohol, ether, and oils. The acids form with it a thick ſaponaceous compound; and with the alkalies it forms a fine ſoap. Expoſure to light and air deſtroys its tranſparency, and gives it a deep brown colour. As to its medical properties and uſes, this oil is ſtimulant, antiſpaſmodic, anodyne, and ſudorific. It was formerly regarded as a remedy of much efficacy in fever, adminiſtered a few hours before the acceſſion of the paroxyſm of intermittents; and was alſo much employed in epilepſy, hyſteria, and all convulſive affections: but it is now almoſt diſcarded from practice, being only uſed occaſionally as an external application to paralytic limbs. The doſe may be from ♏ x to ♏ xxx, in a ſufficient quantity of water. Thomſon's Lond. Diſp.

OIL,

Oil, *Hempſeed*, is of a green colour, and ſtrongly impregnated with the peculiar colour of this plant. The proportion of oil which hemp-ſeed affords is from 20 to 25 *per cent.* In its general properties, uſes, and mode of preparation, it very much reſembles linſeed oil; which ſee.

Oils, *Inflammability of.* See Oil, *ſupra.*

Oil *of Juniper*, or *of Juniper Berries.* (See Juniperus.) Forty-eight pounds of berries yield ſix ounces of oil, of a ſpecific gravity .611. In odour it reſembles turpentine, and its taſte is hot and acrid. It has a greeniſh-yellow colour, is viſcid, and depoſits a fæculent matter when long kept. When genuine it is ſoluble in alcohol. This oil is carminative, diaphoretic, and diuretic. It is ſometimes given in dropſy, and may be added to fox-glove, when it is exhibited in form of pills. The doſe is from ℳ ij to ℳ x, combined with water by means of ſugar or mucilage.

Oil *of Lavender.* (See Lavandula.) One pound and nine ounces of this oil are obtained from eighty pounds of lavender flowers. Its odour is very fragrant, and taſte warm and agreeable; its colour is a pale lemon-yellow, and ſpecific gravity .936. It is ſtimulant and cordial; and is chiefly uſed in hyſteria and nervous head-ache, in doſes from ℳ j to ℳ v, given on a lump of ſugar. Its officinal preparation is unguentum ſulphuris of the Edin. pharmacopeia.

Oil *of Lead*, is a ſolution of ſalt of lead in the eſſential oil of turpentine. This preparation is a powerful antiſeptic.

Oil *of Lemon*, called the eſſence of lemon. (See Lemon.) This eſſential oil is chiefly uſed as a perfume to cover the ſmell of ſulphur in ointments compounded with it. Its officinal preparations are ſpiritus ammoniæ aromaticus, unguentum ſulphuris, and unguentum veratri.

Oil *of Linſeed.* (See Linseed.) The ſeeds of the common flax, conſiſting of a white kernel covered with a thin browniſh ſhell, which cannot be ſeparated from it, are ſubmitted entire to the preſs; but if they are thus treated without any previous preparation, they yield a comparatively ſmall quantity of oil, on account of a ſtrong mucilage that reſides in the ſhell, and abſorbs a large proportion of the oil as it is forced out of the kernel. For this reaſon, and alſo becauſe the cold-drawn oil is not ſo fit for the purpoſes to which this oil is generally applied, the mucilage is deſtroyed before the application of the preſs by the following method. An iron-veſſel, like a ſand-bath, and capable of containing ſome buſhels, is fixed in a furnace; it is then filled with linſeed, and heated by a moderate fire, the contents being carefully ſtirred from time to time, that every part may be equally roaſted: at firſt there ariſes an abundance of aqueous vapour, which, as the heat is increaſed, is followed by denſe blackiſh fumes of a very nauſeous odour. When the torrefaction is completed, the paſte is preſſed in the mill in the uſual way. The proportion of oil yielded by this trial is about 20 *per cent.*; its ſpecific gravity is .9403: it is not congealed except by a cold below 0° Fahr., and its point of ebullition is about 600° of the ſame thermometer. The cold-drawn oil has a high yellow colour, is very unctuous and unpleaſant both to the taſte and ſmell: by expoſure to the air and light it becomes dry. The hot-drawn oil is of a high yellowiſh-red, or deep wine colour, and is more nauſeous than the former: it is of a thicker conſiſtence, and dries without much difficulty in the air, more eſpecially if it has been boiled with a little litharge. The great demand for this oil is in the coarſer kinds of painting, particularly ſuch as is not much expoſed to the weather, as floor-cloths, &c. In medicine it is conſidered as emollient, demulcent, and ſlightly laxative; but as an internal remedy it is ſeldom uſed, on account of its nauſeous taſte; though it has been given with advantage in ileus, when purgatives have failed. It is chiefly employed in the form of a glyſter, in flatulent colic attended with coſtiveneſs, and in abraſions of the rectum; and it is an uſeful application to burns, eſpecially when combined with lime-water. The doſe, when taken by the mouth, is from f. ʒſs f. ʒj; but from f. ʒiij to f. ʒvj may be given at once, per anum. The officinal preparation is the linimentum aquæ calcis of the Edinburgh pharmacopeia, formed by mixing equal parts of linſeed oil and lime-water. Aikin. Thomſon.

Oil *of Mace.* See Mace and Nutmeg.

Oil *of Marjoram.* See Marjoram.

Oil, *Medullary.* See Medullary *Syſtem.*

Oil *of Mercury*, a ſolution of corroſive ſublimate in ſpirit of urine. See Mercury.

Oil *of Mint.* See Mentha.

Oil *of Muſtard.* See *Hedge* Mustard, and Sinapis.

Oil *of Myrrh.* See Myrrh.

Oil *of Nut.* (See Nut-*Oil.*) As the walnut and hazel-nut from which this oil is obtained, chiefly by cold-drawing, come to their full perfection in the warm climate of the ſouth of Europe, they will yield, by proper management, full half their weight of oil. Recent cold-drawn nut-oil is preferred by many to olive-oil, on account of its retaining the exquiſite flavour of the nut; the hot-drawn has an empyreumatic taſte, and is no longer fit for the table: it is, however, much valued by the painter, as being eminently drying, much leſs coloured than linſeed oil, and capable of bearing the injuries of the weather better than any other oil.

Oil *of Nutmeg.* See Nutmeg.

Oil *of Olives* is the moſt popular, and moſt univerſal of all other; being that chiefly uſed in medicine, in foods, ſallads, and in the manufactures.

It is drawn from olives by preſſes or mills made for the purpoſe. The fruit is gathered when at its utmoſt maturity, in November, as it begins to redden: being put under the mill, as ſoon as gathered, care is taken that the mill-ſtones are ſet at ſuch a diſtance that they may not cruſh the nut of the olive. The fleſhy pulp, covering the nut or ſtone, and containing the oil in its cells, being thus prepared, is put into bags made of ruſhes, and moderately preſſed; and thus is obtained a conſiderable quantity of a greeniſh ſemi-tranſparent oil, which, from its ſuperior excellence, is called Virgin oil. The marc remaining after the firſt preſſure is broken to pieces, moiſtened with water, and returned to the preſs, upon which there flows out a mixture of oil and water, which ſpontaneouſly ſeparate by reſt. This oil, though inferior to the former, is of a good quality, and fit for the table. The marc, being again broken to pieces, well ſoaked in water, and fermented in large ciſterns, is again ſubmitted to the preſs, by which is obtained a very conſiderable quantity of a third kind of oil, that is very valuable to the ſoap-boiler and other manufacturers. In ſome countries, particularly in Spain, the olives, inſtead of being gathered by hand, are beaten down, ſo that the ripe and unripe ones are mixed together, and to theſe are added ſuch as have fallen of themſelves, and are therefore more or leſs decayed. All theſe are thrown together in a heap, which ſoon ferments: the olives in this ſtate are ground and preſſed, and thus is procured with leſs trouble a large quantity of oil, of a rank diſagreeable flavour, which none can bear but ſuch as have been accuſtomed to it from their childhood. Recently-drawn Virgin oil has a bland almoſt mucilaginous taſte, with a ſlight but agreeable

agreeable flavour: when expoſed to the air, in an open bottle or caſk, a white fibrous albuminous matter is depoſited, and the ſupernatant oil becomes clear and of a dilute yellow colour: and when this oil is poured off into another veſſel, a ſecond depoſition occurs, and then the oil obtained, being put into clear glaſs phials, may be kept for a conſiderable time, without undergoing any change. But if the oil be allowed to ſtand on the white matter, it becomes in a few weeks very rancid; nor can the common oil, even under proper management, be preſerved in caſks longer than a year and a half, or two years at the fartheſt. The ſpecific gravity of olive-oil is .9153; it boils at about 500° Fahrenheit, and congeals at 36° or 38° Fahrenheit. The facility with which it freezes renders it improper for lamps, eſpecially in cold countries; but by previouſly expoſing it in an open clear glaſs phial to the ſun-ſhine, it may be ſo far amended in this reſpect, as to continue fluid at 21° Fahrenheit. Olive-oil is often ſophiſticated by a mixture of poppy oil, which renders it drying, a quality which the genuine oil does not poſſeſs. In countries that produce it, it is uſed for food, as butter is with us: that of the inferior kinds is burnt in lamps, or employed in the manufacture of ſoaps, which are of a finer quality than thoſe that are compoſed of animal oils. The beſt oil is made in Provence; but that which we receive in this country is brought from Lucca and Florence. It is imported in jars, half-jars, and half-cheſts, which are wooden packages containing flaſks.

Olive-oil is uſed in medicine, internally, as a demulcent in catarrh and other pulmonary affections, diffuſed in water by means of mucilage; and it is alſo given, in large quantities, to mitigate the action of acrid ſubſtances, as ſome poiſons, taken into the ſtomach; and in caſes of worms, applied externally it is a very uſeful relaxant, and inſtead of ſtopping up the cutaneous exhalants, appears to promote the excretion of ſweat, on which account it is beneficially employed in frictions at the commencement of the plague. The body is ordered to be very briſkly rubbed all over with a clean ſponge dipped in warm olive-oil, and the operation is repeated once a day until ſymptoms of recovery appear. Mr. Jackſon relates, that the coolies, who are employed in the oil-ſtores at Tunis, ſmear themſelves all over with oil, and are ſeldom afflicted with the plague when it rages in that city. Frictions with it are uſeful in aſcites. It is alſo uſed as an injection in gonorrhœa; as an adjunct to glyſters in dyſentery and inteſtinal abraſions; and extenſively in pharmacy, in the compoſitions of ointments and plaſters.

The doſe of olive oil is from f.ʒſs to f.ʒj, triturated with mucilage, or mixed with water by means of a few drops of ſolution of potaſs. In caſes of poiſons and worms, as much may be given as the ſtomach can bear. The officinal preparations of oil, beſides cerates and ointments, are Oleum ſulphuratum, L. E. Linimentum ammoniæ fortius, L. E. D. Linim. ammoniæ carbonatis, L. Linim. calcis, D. Linim. camphoræ, L. E. D. Emplaſtrum plumbi, L. E. D. Emp. hydrargyri, E. Emp. oxidi rubri ferri, E. Enema catharticum, D.

For the "oleum ſulphuratum," ſee preparations of Sulphur. For the liniments, ſee Liniment. For the plaſters, ſee Emplastrum and Plaster. Aikin. Thomſon.

Oil *of Orange-peel.* See Aurantii *Cortex.*

Oil *of Origanum.* See Marjoram.

Oil, *Palm*, or *Oil of Senegal*, a thick unctuous liquor, of a yellow colour, and a violet ſmell; ſo called, becauſe drawn, by ebullition, or by expreſſion, from the fruit of a kind of palm-tree, growing in ſeveral places of Africa, eſpecially in Senegal.

Many of the palms produce nuts, which abound in oil. The principal of theſe are the Cocos *Butyracea*, and Elæis *guineenſis*. The ripe fruit is collected in a heap, and ſlightly fermented; it is then coarſely pounded and macerated in hot water, and thus its oil is parted with and ſwims on the ſurface of the water, which by cooling concretes into a ſolid cake. It is purified by waſhing in hot water, and thus becomes fit for uſe. It has a light brown-yellow colour, little or no taſte, but a high odour and flavour like thoſe of the Florentine iris; by long keeping it becomes rancid, and is then nearly white, and almoſt without odour.

The Africans and the Negroes in the Weſt Indies uſe this oil as we do butter; and burn it in their lamps when old. With us, it is only uſed in ſome external applications, for pains and weakneſs of the nerves, cramps, ſprains, and other ſuch complaints. The common people ſometimes apply it to chilblains; and when uſed early, not without benefit. It is alſo employed in the compoſition of the beſt yellow ſoap. It is ſometimes counterfeited with wax, oil of olives, iris, and turmeric; but the trick is found out either by air or fire. The air alters the colour of the genuine, and leaves the counterfeit unchanged; and, on the contrary, fire changes the counterfeit, but does not alter the genuine.

Oil *of Penny-royal.* (See Mentha *Pulegium.*) This oil, which is of a reddiſh-yellow colour, reſembles in its other qualities the oil of pepper-mint. Its ſpecific gravity is .978. It is ſtimulant and antiſpaſmodic, but ſeldom uſed. The doſe may be from ♏ j to ♏ v, given on a lump of ſugar.

Oil *of Jamaica Pepper.* (See Pimento.) This oil has the agreeable odour of the pimento, with its pungent taſte augmented. Its colour is reddiſh-brown, and it is heavier than water. It has the ſame properties with the all-ſpice, but in a greater degree: it is given in dyſpeptic affections, colic, and tympanitis, in doſes of from ♏ iij to ♏ v, rubbed with ſugar, or in any proper vehicle. Its officinal preparation is emplaſtrum aromaticum of the Dublin college. See Plaster.

Oil *of Pepper-mint.* (See Mentha.) This is a common domeſtic remedy in cramp of the ſtomach, flatulent colic, and anorexia; and uſually rubbed up with ſugar or mucilage. The doſe is from ♏ j to ♏ iij. The officinal preparations are pilulæ thei camp. E. Pilulæ aloes cum zingibere, D.

Oil *of Petrol.* See Naphtha and Petroleum.

Oil *of Pimento.* See Pimento, and Oil *of Jamaica* pepper, *ſupra.*

Oil *of Black Pitch.* See Pitch.

Oil *of Poppy-ſeed*, or *Pink-oil*, is extracted by cold-drawing from the ſeeds of the large white poppy (*Papaver ſomniferum*), which is largely cultivated for this purpoſe in France, the Netherlands, and various parts of Germany. It is tranſparent and nearly colourleſs, and when well prepared, has no other taſte or flavour, than a ſlight one of nut-kernels. Its ſpecific gravity is .9288. This is one of the naturally drying oils, and like all of that claſs is frozen with difficulty; it may be cooled down to 0° of Fahr. without congealing. When employed as food, it is ſcarcely to be diſtinguiſhed from olive-oil, which is often adulterated with it. The quantity of oil yielded by a given weight of the ſeeds depends partly on the country and ſeaſon in which the ſeeds are produced, and partly on the mode of extracting the oil. From 100lbs. of freſh ſeeds, ſome ſtate the produce of oil at 25lbs., and others at 58lbs. It is uſed as an article of diet, and in the compoſition of varniſhes, but it is very unfit for burning in a lamp. See Papaver and Poppy.

Oil *of Rape-ſeed.* See Rape, and Oil *of Cole-ſeed.*

Oil, *Red*, in the *Porcelain Manufacture*, a name given to a peculiar

a peculiar colour uſed on the china-ware, or to thoſe pieces of the ware which are coloured with it. It is a very elegant ornament, and would be worthy our attempting to imitate in England, on our better ſorts of wares. They do it in the following manner: they mix the red colour, called *tamlan-hum*, or the copperas red (ſee PORCELAIN) with *oil of ſtone*, and with another oil, as they expreſs it, of the ſame kind, made of a whitiſh ſort of pebble, or agate, found on the ſhores of their rivers, and the place of which might probably be ſupplied with us by common cryſtal. The powder is to be thoroughly mixed with theſe liquors, and the veſſel dipt carefully into the mixture, or ſome parts of it only covered with it in figures: after this, it is to be ſet by to dry, and, when thoroughly dried, it is to be baked in the common way. The general method is that of covering the veſſel all over, both inſide and out, with this red; and it comes out of the moſt bright and brilliant colour imaginable, but it will not ring when ſtruck upon, as our common china-ware does. We ſeldom ſee this in any degree of perfection, but it is very elegant when fine.

OIL, *Rock*. See PETROLEUM.

OIL *of Roſemary*. (See ROSEMARY.) Twenty-four pounds of the plant yield one ounce of a fluid colourleſs oil, the odour of which is leſs agreeable than that of the plant. It depoſits cryſtals of camphor when long kept. Its ſpecific gravity is .934. As to its medical properties, it is ſtimulant, and frequently enters into the compoſition of liniments. The doſe, as an internal remedy, may be from ♏ ij to ♏ vj; but it is ſcarcely ever ordered. The officinal preparations are tinctura ſaponis, and alcohol ammoniacum aromaticum.

OIL *of Rue*. (See RUTA.) Twenty-one pounds of rue yield 59 grains of oil, which has the ſtrong ungrateful odour and taſte of the plant. When recently drawn the colour is yellow, but it deepens into brown by age, and depoſits a browniſh reſinous ſediment. It congeals at 40° Fahr. Oil of rue is ſtimulant and antiſpaſmodic; it is ſometimes given in hyſteria, and the convulſive affections of children attendant on dentition; and is alſo occaſionally uſed as a rubefacient in palſy. The doſe is from ♏ ij to ♏ v, triturated with ſugar or mucilage.

OIL *of Sage*. See SAGE.

OIL *of Saſſafras*. (See SASSAFRAS.) Sixty pounds of ſaſſafras yield 12 ounces of a viſcid yellow oil, heavier than water; its ſpecific gravity being 1.094. Its odour is fragrant, and its taſte hot and acrid, excoriating the lips when incautiouſly taſted.

The oil of ſaſſafras is peculiarly liable to cryſtallization in certain circumſtances, and that into the moſt beautiful forms. Mr. Maud gives an account of a quantity of this oil, which having ſtood expoſed to the air in a very froſty night, in an open veſſel, was in the morning found changed three parts in four of it into very beautiful and large cryſtals: they were of an hexagonal form, very tranſparent, and of three or four inches in length, and half an inch in thickneſs. Theſe cryſtals ſubſided in water, and were indiſſoluble in it; they were readily inflammable at the fire, and were reduced by heat to their priſtine fluid ſtate: hence it is evident that they ſtill retain the natural qualities of an oil, though they appear under ſo very different a modification of their parts. What is moſt remarkable in this change, is, the metamorphoſis of a fluid to a ſolid body, of ſo determinate and regular a figure, and that theſe cryſtals ſhould be perfectly clear and colourleſs, though the liquor from which they froze was of a yellowiſh colour, not unlike that of Madeira wine.

This oil is ſtimulant, and ſuppoſed to be alſo ſudorific and diuretic. It has been given in chronic rheumatiſm, ſcurvy, and ſome cutaneous affections. The doſe is from ♏ ij to ♏ x, but it is ſcarcely ever ordered.

OIL *of Savine*. (See JUNIPERUS.) Two pounds of ſavine are ſaid to yield five ounces of oil, which is limpid, of a pale yellow colour, having the odour of the plant, and being very acrid to the taſte. This oil is the principle on which the virtues of ſavine depend; hence it poſſeſſes the ſame properties, and is applicable to the ſame purpoſes as the plant. The doſe may be from ♏ ij to ♏ vj, triturated with ſugar.

OIL *of Spearmint*. (See MENTHA.) The flavour of this oil is ſimilar to that of pepper-mint, but leſs grateful; its taſte is warm, and leſs pungent; its ſpecific gravity is .975, and its colour greeniſh. Its medical properties are the ſame with thoſe of oil of peppermint. The doſe is from ♏ ij to ♏ v, given on a lump of ſugar. Its officinal preparation is infuſum menthæ compoſitum, which is prepared, according to the directions of the Dublin college, by taking of the leaves of ſpearmint, dried, two drachms, and a ſufficient quantity of boiling water to afford ſix ounces by meaſure when ſtrained; digeſting for half an hour, but ſtraining the liquor when cold, then adding of refined ſugar two drachms, oil of ſpearmint, three drops diſſolved in half an ounce (fluid?) of compound tincture of cardamoms; and mixing the ingredients. This is a grateful ſtomachic, and is ſlightly diaphoretic. It may be ſerviceable in anorexia and nauſea, and as a vehicle to cover the diſagreeable taſte of other medicines. The doſe may be from f. ʒj to f. ʒiij, or at pleaſure.

OIL, *Stillatitious*. See STILLATITIOUS.

OIL *of Stone*. In the manufacture of the Chineſe porcelain, they uſe a liquid matter of a white colour, which they call by this name, on which their great myſtery of finiſhing their work depends; yet this has been leſs enquired into by the imitators of that ware in Europe than many other articles of leſs conſequence. The ſtone of which this oil is made, is of the ſame degree of hardneſs with that which the petunſe is prepared of. They procure it from quarries, and chooſe ſuch as is of a good white colour, and has many dark green ſpots in it.

Theſe ſpots are of the colour of the leaves of cypreſs. Sometimes a ſtone is choſen which has a brown ground, variegated with ſpots and blotches of a reddiſh colour. They firſt carefully waſh this ſtone; then laying it in a clean place, they break it to pieces with iron inſtruments, and afterwards grind theſe to a perfectly fine and impalpable powder, by rubbing them in large mortars, with peſtles of ſtone faced with iron, and turned either by the labourers, or by water. When the whole is thus reduced to a fine powder, they throw it into a veſſel of water; and ſtirring it briſkly about, they let the coarſer part ſubſide to the bottom, and there ſwims a fine thick matter like cream, for two or three inches depth on the ſurface. This they carefully ſkim off, and putting it into another veſſel, of clear water, they let it throw down any coarſe matter it may yet contain; and, finally, taking off the thick ſurface again, they mix this with ſome freſh water in another veſſel, and leave it to ſubſide; then pouring on the clean water, they take out the remainder at the bottom of the veſſel, which is perfectly fine, and reſembles a thick cream. To every hundred pounds of this they add one pound of a ſubſtance of the nature of which we are not yet perfectly informed. It is ſaid to be a mineral reſembling alum. They calcine this firſt, and then beat it to a fine powder; and this being added to the cream, or oil, as it is called, ſerves to keep it always in the ſame liquid ſtate. This ſubſtance, when finiſhed in this manner, has very little title to the name of an oil; it is rather a varniſh, and is always uſed in mixture with another varniſh, which

is called at this time fern oil, and uſed to be called lime oil; it is prepared in the ſame manner with the other after burning. See FERN-*Oil.*

OIL *of Sulphur* is a name given to the concentrated acid of ſulphur. See OIL, *ſupra*, and SULPHUR.

OIL *of Tartar.* See TARTAR.

OIL, *Train.* See *Whale* FISHERY, TRAIN, and WHALE.

OIL *of Turpentine* is obtained by diſtilling the reſin with water in a common ſtill, when the oil is found in the receiver ſwimming on the water, from which it is eaſily ſeparated. The average proportion is 60lbs. of oil from 250lbs. of good turpentine. This proceſs is carried on both abroad and at home; but the oil drawn in this country is always preferred. (See PINUS, and TURPENTINE.) The Dublin college directs 5lbs. of turpentine and four pints of water, and the oil to be diſtilled from a copper alembic. Yellow reſin will remain in the retort after the diſtillation.

The *rectified* oil of turpentine of the London and Dublin college is obtained from a pint (two pints Dub.) of oil of turpentine, and four pints of water. Diſtil the oil (a pint and a half of the oil, Dub.)

Purified oil of turpentine of the Edinburgh college is obtained from 1lb. of oil of turpentine, and 4lbs. of water; and diſtilling as long as any oil paſſes over. The rectification of the oil is a troubleſome proceſs, and on account of the great inflammability of the vapours, much caution is required to prevent them from eſcaping through the lutings of the veſſels, and catching fire. The rectified oil is a little lighter than the common oil, and completely free from any reſinous admixture; but in other reſpects it has no peculiar excellence to recommend it. What remains in the retort is a thick reſinous matter, and is denominated "balſam of turpentine." (See BALSAM.) For the chemical and medicinal properties of oil of turpentine, ſee PINUS, TURPENTINE, and TAPE *Worms*.

OIL *of Venus*, a name given by Lemery to the ſalt formed by the union of copper with the nitrous acid, when it is reſolved into a liquor by the moiſture of the air. This is a cauſtic and eſcharotic.

OIL, *Virgin*, is underſtood of oils expreſſed from olives, nuts, &c. freſh gathered, without being heated, too much preſſed, &c. See OIL *of Olives.*

OIL *of Vitriol.* See SULPHURIC *Acid* and VITRIOL.

OILS, *Volatile.* (See OIL, *ſupra.*) For the method of preparing theſe oils by the London college, ſee *Diſtilled* OILS, and for thoſe of the Dublin college, ſee *Eſſential* OILS, *ſupra.* The Edinburgh college directs the volatile oils to be prepared in the ſame manner as the diſtilled waters, except that leſs water is to be added. Seeds and woody ſubſtances muſt be previouſly bruiſed or raſped. The oil diſtils over with the water, and, as it is lighter or heavier, floats on the ſurface or ſinks to the bottom, and is afterwards ſeparated. It is neceſſary to obſerve, in preparing theſe oils, and alſo the diſtilled waters, that the quality of the ſubſtances, their texture, the ſeaſon of the year, and ſimilar circumſtances, muſt occaſion ſo many differences, that no general rules, that are applicable to every caſe, can be laid down. Few of the volatile oils are prepared by the apothecary. The oils of aniſe, chamomile, juniper, origanum, roſemary, and pimento, are uſually imported into this country; while thoſe of lavender, peppermint, ſpearmint, and penny-royal, are annually prepared on a large ſcale.

As medical agents, volatile oils are ſtimulant and ſtomachic. They are chiefly employed to remove nauſea and flatulence, to correct the griping qualities of ſome purgatives, and the diſagreeable taſte of other remedies. They may be given triturated with water and mucilage; or dropped firſt on a lump of ſugar, and through its medium diffuſed in water, forming a ſolution of what has been denominated "oleum ſaccharinum." The quantity of ſugar muſt be more than ten times the weight of the oil; and when they are well triturated together the oil becomes thus completely ſoluble in water, and may be diluted to any extent. Some of the more ſtimulant of theſe oils are added to embrocations to be uſed as rubefacients in caſes of numbneſs, pains, and paralytic affections of the joints. Thomſon.

OIL *of Wax.* See WAX.

OIL frequently takes new names from the drugs mixed with it; as *oil of roſes*, which is that mixed with roſes; *oil of jeſſamy*, that perfumed with jaſmin.

OIL *of Wine.* See ETHER.

OIL, *Anointing with.* See UNCTION.

OIL-*Bag*, a veſſel in birds replete with an unctuous ſubſtance, ſecreted by one ſometimes two glands, for the purpoſe, diſpoſed among the feathers; which being preſſed by the bill or head, emits its oily matter for dreſſing and pruning the feathers. See *Anatomy of* BIRDS.

OIL *Beetle.* See *Oil* BEETLE.

OIL-*Bladders*, in *Vegetable Phyſiology*. See *Secretions of* VEGETABLES.

OIL-*Dregs.* See DREGS.

OIL, *Gilding in.* See GILDING.

OIL, *Painting in.* See PAINTING.

OIL *Mill*, in *Mechanics*, is a machine uſed to expreſs oil from linſeed, rape-ſeed, and other oleaginous grain, but chiefly from the above-mentioned for the uſe of painters. Olive and other vegetable oils, the produce of the ſouth of Europe, are alſo expreſſed by a machine, but it is not called a mill, being ſimply a ſtrong ſcrew-preſs, provided with a windlaſs or capſtan, to give it a greater power; in ſhort, it is the ſame machine as the CYDER *Preſs* (ſee that article). The olives are firſt pounded, or bruiſed, either in a large mortar, or by a running ſtone, in the ſame manner as the apples for making cyder. The pulp thus produced is put up in bags made of horſe-hair, and a pile of theſe, being made up under the preſs, the ſcrew is forced down by men working at a long lever, and the oil expreſſed: it runs very freely at firſt, and this, which is eſteemed the beſt quality, is in ſome countries kept ſeparate. When this preſſure has continued an hour or two, the power of the capſtan is applied. This produces a good quantity of oil of the ſecond quality, which is ſold at an inferior price; and in ſome provinces of Spain, where the olive is extenſively cultivated, it is uſed to burn in their lamps.

The oil-mill we intend to deſcribe in this article is for a different purpoſe; *viz.* the expreſſing of linſeed and rape-ſeed oils. Theſe grains are exceedingly hard and ſmooth on their ſurfaces, and the fragments of their ſhells, however broken, form little concavities which will retain the oil, unleſs a far greater preſſure is applied than can be obtained by a ſcrew-preſs; it is, therefore, done by a wedge-preſs. This conſiſts of a ſtrong block of wood, or a caſt iron frame, in which a long mortiſe is made: in this a bag of bruiſed ſeed is placed at each end, and blocks being put in to fill up the mortiſe, a wooden wedge is introduced between the blocks, and driven in by repeated blows of a heavy ſtamper, which is raiſed up by the power of the mill, and let fall upon the wedge, till it has driven it down as far as it will go. This cauſes a moſt immenſe preſſure upon the ſeed contained in the bags, and forces out the oil at every blow of the ſtamper: for it is a curious fact that the ſame preſſure,

preſſure, gradually produced, will not expreſs any ſenſible quantity of oil; it muſt, therefore, be done by a ſudden and violent acceſſion of force; accordingly, at every ſtroke upon the wedge, the oil exudes in conſiderable quantity from the ſeed, until the whole is expreſſed, leaving a cake of ſeed as hard as a piece of board. Theſe oil-cakes are very good food for cattle.

The machinery of an oil-mill is explained by the drawing in *Plate Oil-mill*, where *fig.* 1. is a plan, and *fig.* 2. an elevation, of a very good mill of this kind, which was erected after the deſigns of the late John Smeaton, eſq. F.R.S.; whoſe proportions for the parts of mills have been ſcarcely improved ſince his time; though in the conſtruction of the wheels, &c. caſt iron has of late years been ſubſtituted for wood almoſt univerſally. A, in both figures, is the water-wheel actuating the whole mill; it is underſhot; that is, the water paſſes under it, and turns the wheel, by its momentum ſtriking upon the floats. (See WATER-WHEEL.) It works very cloſe, in a pit formed between the two walls *c*, C, the latter being the outſide wall of the mill-houſe: it is framed on a ſtrong octagonal ſhaft B B, turning on two gudgeons fixed in its ends: D is the pit-wheel, or great cog-wheel, fixed upon the main ſhaft, within the houſe: it has wooden teeth fixed in its rim, parallel to its axis, in the manner of a crown-wheel. There are 80 of theſe teeth, by which it turns a ſmaller wheel, E, of 37 teeth, fixed on an horizontal ſhaft, F, called the tumbling ſhaft, extending nearly acroſs the houſe. It gives motion to the ſtampers, V, W, of the preſs, and alſo the rolling ſtones or runners, I, K, which bruiſe the ſeed. The latter is done by means of a wheel, G, with 35 teeth, fixed on the end of it, for the purpoſe of turning a large wheel, H, of 72 teeth, which is fixed upon a vertical ſhaft, *n*, which gives motion to the running ſtones, I, K. Theſe are two circular ſtones, fitted upon an iron axle, the ends of which are ſhewn at *a a*. This axle paſſes through the vertical ſhaft *m*, and alſo through runners: thus they have two motions, a rotation round their own axis, by which they are carried round upon the nether or horizontal mill-ſtone, L, on which they roll. The centre-holes in theſe running mill-ſtones are made a little wide, and the hole in the ſhaft *m*, which carries the middle of the iron axis, is made oval up and down. This great freedom of motion is neceſſary for the runner mill-ſtones, becauſe frequently more or leſs of the grain is below them at a time, and they muſt therefore be at liberty to get over it without ſtraining the ſhaft.

The lower mill-ſtone, L, is ſupported on maſonry, and ſurrounded by a border or ledge of wood *d d*, which prevents the ſeed being ſcattered: the two ſtones I, K, as the figure ſhews, are placed at different diſtances from the central axis *m*, ſo that they run in different paths, and thus bruiſe the ſeed more effectually than if they followed each other in the ſame circuit: *n*, *n*, are the ends of two wooden rails, projecting from the ſhaft *m*, and at their ends ſupporting two upright pieces of wood, which, at their inferior extremities, carry ſweeps or rakes: theſe drag round upon the ſurface of the lower ſtone, and turn the ſeed about, to receive the greateſt poſſible action from the ſtones I, K, rolling over it. There are two of theſe ſweeps on the oppoſite ſides of the ſtones, one called the outer rake, and the other the inner rake. The outer rake collects the grain under the runner from the ſurface of the border *d*. In this manner the grain is turned over and over, and cruſhed in every direction. The inner rake lays the grain in a ſlope or ridge, over which the runners paſs, and cruſh it: then the ſecond rake lifts it again into a ridge, to receive the action of the next ſtone, ſo that every ſide of the grain is preſented to the runner mill-ſtone, and receives its action, while the reſt of the lower ſtone is ſwept by them ſo clean, that not a ſingle grain is left on any part of it. The outer rake is alſo furniſhed with a rag of cloth, which rubs againſt the border of a hoop which ſurrounds the nether mill-ſtone, ſo as to drag out the few grains which might otherwiſe remain in the corners. There is alſo another ſweep, making part of the inner rake, which is occaſionally let down for ſweeping off all the ſeed when it has been ſufficiently bruiſed. The preſſure and action of theſe rakes are adjuſted by means of wooden ſprings, which cannot be eaſily and diſtinctly repreſented by any figure. The oblique poſition of the rakes (the outer point going foremoſt) cauſes them to ſhove the grain inwards, or towards the centre, and at the ſame time to turn it over ſomewhat in the ſame manner as the mould board of a plough ſhoves the earth to one ſide, and partly turns it over. Some mills have but one ſweeper, and indeed there is great variety in the form and conſtruction of this part of the machinery. The great pit, D, turns a ſmall cog-wheel *e*, *fig.* 1, on whoſe ſpindle is fixed one of the two iron rollers *f*, *g*, which are uſed for bruiſing the ſeed, as in the firſt operation.

Theſe rollers are made of caſt iron, and truly turned in a lathe, their ſpindles turning in braſs buſhes, fixed in iron frames bolted down to the wood work. Theſe frames have mortiſes in them, in which the buſhes for the pivots of the roller, *g*, are placed, with liberty to ſlide in the mortiſes when they are puſhed up by ſcrews ſcrewed through the ends of the iron frames. By theſe means the rollers can be ſet at any diſtance apart, according to the ſize of the ſeed which is to be cruſhed between them; *l*, *l*, are two ſmall iron cog-wheels, of 15 teeth each, fitted on the ends of the pivots of the rollers; they make both rollers turn together with the ſame motion: the ſeed is put into a hopper, ſupported at ſome diſtance above the roller, and it runs out at an opening in the bottom into a trough called the ſhoe, which is continually ſhaken by means of a piece of wood nailed to it, and reſting upon the cog-wheel *l*. By this means the ſhoe continually feeds the rollers with a ſmall quantity of ſeed, without any danger of choaking them up, and the ſeeds fall, from the end of the ſhoe, between the rollers, which, as they turn round, take the ſeed in between them, and bruiſe it. It is proper to have a piece of iron plate nailed to ſome part of the frame, and kept conſtantly preſſing againſt the rollers, ſo as to ſcrape off the ſeed which may adhere to them. The ſeed, after having paſſed between the rollers, falls upon an inclined board, placed in the frame beneath them, and is thus ſhot down in a heap before the rollers, from whence it is conveyed by a labourer to the rolling ſtones.

The preſs comes next to be noticed, for we have hitherto only deſcribed the machinery for bruiſing the ſeed previous to expreſſing the oil from it.

The tumbling ſhaft, F, has two lifters, M, N, projecting from it, which as it turns round lifts up and lets fall the ſtampers, V, W, of the preſs. They riſe and fall in a frame conſiſting of two thick pieces of wood P, P, firmly bolted together at the bottom by beams T, T, extended between them. The ſpace between theſe beams is filled up by the bags of ſeed at *d*, *d*, *fig.* 2, the preſſing wedge *b*, the diſcharging wedge *c*, and blocks of wood, to keep them at the proper diſtance apart.

The beams, T, T, have croſs pieces upon them, between which the ſtampers, V, W, ſlide up and down: they are lifted up by the wipers or lifters M, N, fixed upon the ſhaft F: theſe take hold of tappets or chocks projecting from the ſtampers, and raiſing them to the proper height, let them fall on the wedges. When they are to be ſtopped, the workman pulls a rope, which raiſes a lever, and holds up the ſtamper too high to meet the lifter in its revolution. The

inverted

inverted wedge, *c*, is ſuſpended by a rope from a wooden ſpring, which raiſes it up, as in the figure, when the other wedge is taken out for the purpoſe of putting a freſh charge of ſeed in the bags at *d d*. The opening of the preſs, or the ſpace contained between the uprights, P, P, of the frame, and the two beams T, T, has a very ſtrong caſt iron frame within it, which reſiſts the preſſure to rend the preſs open. The upper edge of this frame is ſhewn by the dark line in *fig.* 2, and the internal parts are ſhewn by dotted lines.

The bags of ſeed, *d*, *d*, are included between two iron plates, united together at the bottom in the manner of book lids, and the bag is ſhut up between them: immediately beneath theſe are ſmall holes in the bottom of the preſs, at which the oil oozes out into ſmall pots *k*, *k*: the blocks which fill up the preſs reſt upon the bottom of the preſs, to prevent them being carried down by the action of the wedges which ſlide againſt them, having thin pieces of wood between, to make them ſlide eaſily by each other: the preſſing wedge, *b*, has its point downwards, and is driven by the ſtamper V: the diſcharging wedge *c* is inverted, its ſmalleſt end being upwards; and this, when ſtruck by the ſtamper W, is forced down, and thus releaſes the preſs, when it would be exceedly difficult to diſengage it by any other means, the preſſing wedge being driven in very faſt by the repeated blows of the ſtamper V.

There is likewiſe a ſmall apparatus in an oil-mill called the fire gear or chaufer pan, which we have omitted in our plate. It is intended to keep the bruiſed ſeed ſtirring whilſt it is heated in a copper pan, previous to preſſing, as this is found to increaſe the produce of oil. The chaufer pan conſiſts of a ſmall fire-place, ſituated in the corner of the mill-houſe, and heated by burning charcoal in it. The ſeed is contained in a circular copper pan, which is ſet over the fire, and the ſeed is prevented from burning to the bottom of the pan, by a croſs piece of iron fixed to the lower end of a vertical ſpindle, which, as it turns round in the pan, ſtirs the ſeed. The ſides of this croſs are ſet inclined, ſo as to ſcrape the ſeed from the bottom of the pan, and throw it over the back of the ſtirrer. The ſpindle for the ſtirrer is put in motion by means of a train of ſmall wheelwork, receiving motion from a rigger or pulley fixed upon the tumbling ſhaft F, by means of an endleſs chain or rope. In many of the moſt improved mills the chaufer pan is heated by ſteam inſtead of charcoal: in this caſe it has a falſe bottom on which the ſeed lays, and the ſteam from a boiler is admitted into the ſpace beneath the bottom. This is found to give the proper heat with greater preciſion than can be done (except by experienced workmen) with the charcoal fire; for if the heat is too great it makes the oil rancid, and if it is too low the produce of oil will be diminiſhed. In either caſe the pan muſt have a ſmall opening on one ſide, and a ſluice to ſhut it up and keep in the ſeed until it is properly heated. Immediately beneath the door are two hoppers, which lead the ſeed down at the ſide of the furnace, and conduct it into the flannel bags, which are hung at the lower extremity, or ſmall openings of the hopper. When the ſeed is ſufficiently heated, and the preſs is ready for it, the ſluice is opened, and the ſtirrer throws the ſeed out into the hoppers and the bags. Theſe are made of flannel-cloth, which is found the beſt ſubſtance to reſiſt the preſſure and admit the oil through. The bags, before they are put into the preſs, are flattened by the hand, and wrapped up in a long ſlip of very thick leather, which encloſes it, and prevents the bag being burſt by the preſſure.

Our readers will now comprehend the ſtructure of the oil-mill; but as in all operations of this nature much management is requiſite to carry them on to the beſt effect, we ſhall briefly deſcribe the proceſs followed by our moſt careful manufacturers of oil.

Linſeed and rape-ſeed are the produce of almoſt every county in England, and as the conſumption of the oil for painting is not confined to particular places, the manufacture is carried on in every part of the kingdom. A great number of oil-mills are to be met with in Hull, and other parts of Yorkſhire, where they have the advantages of falls of water. The ſeed is firſt bruiſed between the rollers, to crack every grain without ſeparating their parts: this very much facilitates the operation of the grinding, for the grains are ſo hard and ſmooth, that they ſlip away from beneath the runner-ſtones, and it would require a long time to get all the grains cruſhed; but by the rollers every grain is broken, and then the runner-ſtones act with proper effect. The rollers require ſo much power, that in ſmall mills they cannot drive the other machines at the ſame time; but this is no objection to them, becauſe they act with ſuch rapidity, as in a very ſhort time to bruiſe ſeed enough for the whole day's work. The ſeed, after being cruſhed between the rollers, is ſpread by a ſhovel upon the nether mill-ſtone L, to be ground by the runners. That this may be more expeditiouſly done, one of the runners is ſet about two-thirds of its own thickneſs nearer the ſhaft than the other. Thus they have different circuits, and the grain, which is a little heaped towards the centre, is thus bruiſed by both. The inner rake gathers it up under the outer ſtones into a ridge, over which the ſtone paſſes and flattens it: it is then gathered up again by the outer rake into a ridge under the inner ſtone. The outer rake conſiſts of two parts; the outer part preſſes cloſe on the wooden border *d d*, which ſurrounds the nether ſtone, and ſhoves the ſeed obliquely inwards, while the inner part of this rake gathers up what had ſpread towards the centre.

The outer rake has a joint near the middle of its length, by which the outer half of it can be raiſed from the nether ſtone, while the inner half continues preſſing on it, and thus ſcrapes off the moiſt ſeed, which is like a paſte. When the ſeed is ſufficiently bruiſed, the miller lets down the outer end of the rake; this immediately gathers the whole charge, and ſhoves it obliquely outwards to the wooden rim, where it is at laſt brought to a part that is left unboarded, and it falls to the ground. In the Dutch mills it falls through troughs placed to receive it. Theſe troughs have holes in the bottom, through which the oil drips all the time of the operation. This part of the oil is conveyed into a peculiar ciſtern, being conſidered as the pureſt of the whole, having been obtained without preſſure, by the mere breaking of the hull of the ſeed.

The ſeed in this country is ſeldom ſo ripe as to yield any oil in this ſtage without preſſure; but in ſome mills they take a quantity of their beſt ſeed from the ſtones, and putting it into bags give it a moderate preſſure by a ſcrew-preſs. The oil thus obtained is called cold drawn, and is ſold at a higher price for the uſe of cabinet makers, who rub their ornamental wood work with it to give a poliſh: in other work, the cold drawn oil is nothing more than the firſt obtained by the preſs, but without heating the ſeed.

In ſome of the Dutch mills, a much greater quantity of oil is obtained in the grinding, without preſſure, by having the bed of maſonry, which ſupports the lower mill-ſtone, formed into a little furnace and gently heated. But the utmoſt care is neceſſary to prevent the heat from becoming conſiderable. This enabling the oil to diſſolve more of the fermentable ſubſtance of the ſeed, expoſes the oil to the riſk of growing ſoon very rancid, and in general it is thought a hazardous

a hazardous practice, and the oil does not bring ſo high a price.

When the ſeed is very dry, a little water is thrown in among it whilſt grinding, which is found to facilitate the proceſs. In about twenty minutes a charge of ſeed will be ſufficiently ground, and is then carried to the chaufer pan, where it is heated previous to being preſſed. Here the ſtirrer keeps it from burning to the bottom of the pan: while this is doing the wedges of the preſs are taken out, both the ſtampers are hauled up, and the iron lids at *d d*, which are to include the bags of ſeed, are opened out ready to receive them. When the ſeed is ſufficiently heated the ſluice is opened, and the ſtirrer throws it out into the bags, the workman flattens them, wraps them in the leather, and puts them into their places. The wedge, *b*, is now introduced, and the ſtamper, V, diſengaged to drive it down. After a few blows the oil begins to run, and this continues till the wedge gets ſo faſt, that the ſtamper will rebound up from it two or three times: it is then judged that it can be driven no farther. The ſtamper, V, is now hauled up, and the other let looſe. This at one or two blows drives down the wedge W, and relieves the preſſure, after which the wedge and the bags may be taken out to put in a freſh charge. The contents of the bag are compreſſed into a denſe cake, from which the bag is ſtripped off, and the cakes are ground up, and ſubjected to a ſecond preſſure. They are broken into pieces by the ſhovel, and thrown under the runners, where the cake is again broken down, and the parenchyma of the ſeed reduced to a fine meal. Thus free egreſs is allowed to the oil from every veſicle in which it is contained. But it is now rendered much more clammy by the forcible mixture of the mucilage, and even of the finer parts of the meal. When ſufficiently ground the workman conveys the paſte to the chaufer pan, where it is heated rather more than for the firſt time, and the ſecond preſſure is conducted in the ſame manner as the firſt. The produce of oil from the ſecond operation is very uncertain; as it depends upon a number of circumſtances. It will ſometimes exceed the quantity of the firſt time, and at other times it will not be half as much. The bags for the ſecond preſſure are filled with twice as much ſeed as the firſt time, and the cake will be more than twice as thick. The linſeed cakes are ſold at a high price for cattle, but the rape-ſeed cakes are ground to a coarſe powder, and in that ſtate ſold for manure.

The mill ſhewn in our plate is on a ſmall ſcale, but many mills have from 10 to 15 preſſes in uſe. A preſs will generally preſs ſeven cwt. of ſeed *per* day the firſt time, but only two, or two and a half cwt. for the ſecond time, becauſe it requires as much more time for the laſt operation.

Reſpecting the produce of oil from linſeed, we have found from an average of four months work of an oil-mill in Yorkſhire, that 280 quarters of linſeed, generally weighing 30 ſtone (of 14lbs. each) *per* quarter, produced 5616 gallons of oil, which is at the rate of $20\frac{2}{3\,5}$ gallons *per* quarter. The greateſt produce in the period from which this average was obtained, was 409 gallons from 20 quarters, or $20\frac{9}{10}$ gallons *per* quarter. The leaſt produce was $19\frac{4}{5}$ gallons *per* quarter.

Oil-*Stone*, *cos olearia*, in *Natural Hiſtory*, is a ſtone of a whitiſh colour, with a faint mixture of a blueiſh-grey; and it is ſometimes ornamented with black ſpots and dendritæ. It is of a moderately fine and compact texture, hard and heavy, and capable of a tolerable poliſh. It is not acted upon by acids, gives fire very freely with ſteel, and when burnt, acquires a pure white colour. This ſtone has not yet been found in England; but in the eaſtern parts, and in Germany, there are large ſtrata of it. It is much uſed by our artificers for ſetting a fine edge on their tools, and is only uſed with oil, which by degrees changes its colour to a deep brown. They call it the Turkey-ſtone. De Coſta's Hiſt. of Foſſils, p. 153.

Oil-*Tree*, in *Botany*. See Ricinus.

Oil *Creek*, in *Geography*, a river of America, in Alleghany county, Pennſylvania, which iſſues from a ſpring, on the ſurface of which floats an oil, ſimilar to that called Barbadoes tar, and which runs into Alleghany river. The oil is found in ſuch quantities, that a perſon may gather ſeveral gallons in a day. Thoſe who have been affected with rheumatic complaints have found relief by bathing their joints in this oil; and the water drank freely, has operated as a cathartic.

OILS, in *Agriculture*, a provincial term uſed to ſignify the beards, or prickles of barley, &c.

OILY Grain, in *Botany*. See Sesamum.

The ſeſamum, with oblong entire leaves, called the Eaſtern fox-glove, is much uſed by the Egyptians and African Negroes, both as food and medicine. The Arabians call the expreſſed oil of the ſeeds *zeid taib*, that is, good oil, by way of eminence, becauſe it is of frequent uſe with meats; and in Egypt is ſold dearer than oil of olives. Parkinſon.

Oily *Waters*. See Waters.

OINGHT, or Yoingt, in *Geography*, a town of France, in the department of the Rhone and Loire; 7 miles W.S.W. of Villefranche.

OINTMENT, in *Pharmacy* and *Surgery*, &c. See Unguent.

OIRSBECK, in *Geography*, a town of France, in the department of the Lower Meuſe, and chief place of a canton, in the diſtrict of Maeſtricht. The place contains 803, and the canton 10,340 inhabitants, on a territory of 100 kiliometres, in 14 communes.

OISE, one of the twelve departments of the ſecond or northern region of France, formerly Beauvaiſis, deriving its name from the river Oiſe, which joins the Seine, 5 miles S. of Pontoiſe. It is ſituated N. of the Seine and Oiſe, in N. lat. 49° 25′, and bounded on the N. by the department of the Somme, on the E. by that of the Aiſne, on the S. by the departments of the Seine and Marne, and Seine and Oiſe, on the W. by the departments of the Eure and the Lower Seine. It is 27 French leagues in length, and 18 in breadth, and contains 6082½ kiliometres, or 298 ſquare leagues, and 369,086 inhabitants. It is divided into four circles, or diſtricts, 35 cantons, and 738 communes. The circles are, Beauvais, comprehending 122,786 inhabitants; Clermont, 84,942; Compiegne, 88,048; and Senlis, 73,310. According to Haſſenfratz, the circles are 9, the cantons 76, and the number of inhabitants 385,206. The capital is Beauvais. The contributions, in the 11th year of the French era, amounted to 4,714,895 fr. and the expences to 293,983 fr. 33 cents. The ſoil in this department, conſiſting of plains and eminences, is of different qualities, but in general is fertile, yielding grain, flax, paſture, &c.

OISEAU, in *Conchology*, the name of a peculiar ſpecies of oyſter, of ſo remarkable a figure, that it repreſents a bird, with its wings expanded, and has a ſmall protuberance at the hinge, repreſenting a head, and a long proceſs at the oppoſite end, which very well repreſents a tail. It is of a duſky reddiſh colour on the outſide, and of a fine pearly hue within. When the outſide of this ſhell is taken off, and it is nicely coloured, by cutting it down to a proper depth in every part, it is of a fine reddiſh yellow, and is the aurora ſhell of collectors.

OISEL, James, in *Biography*, profeſſor of law at Groningen,

ningen, was born at Dantzic in 1631, and died in 1686. His works are corrections and notes on various authors, a treatiſe entitled "Theſaurus ſelectorum Numiſmatum antiquorum ære expreſſorum," and a "Catalogue" of his library, which was large and valuable. Moreri.

OISELE, in *Geography*, a town of Weſtphalia, in the biſhopric of Oſnabruck; ſix miles E.S.E. of Oſnabruck.

OISEMONT, a town of France, in the department of the Somme, and chief place of a canton, in the diſtrict of Amiens; 21 miles W. of Amiens. The place contains 1030, and the canton 10,339 inhabitants, on a territory of 165 kiliometres, in 35 communes.

OISTER, in *Zoology*. See Oyster.

Oister's *Town*, in *Geography*, a town which ſtands on a bay, to which it gives name, near the ſouthern extremity of the iſland of Barbadoes, formed to the S.E. by Kendal's point, and well defended by forts; four miles E.S.E. of Bridgetown.

OISY, a town of France, in the department of the ſtraits of Calais; eight miles S. of Douay.

OITAMA, a town of Japan, in the iſland of Niphon; 25 miles N.W. of Mogani.

OITS. See Omi.

OKA, or Okka, a river of Ruſſia, which riſes in the government of Orel, and after watering that and the governments of Kaluga, Tula, Moſco, Rezen, Tambof, Vladimir, and Niſhnei-Novgorod, falls at the city of the laſt-mentioned name into the Volga. This is a very conſiderable river, navigable to its upper regions, taking up a multitude of ſmaller ſtreams, and thus effecting an excellent communication between moſt of the inland governments of the empire. On its left it receives the Ugra, the Moſkva, and the Kliaſma; and on its right, the Upa, the Oſetr, and the Moſkſha.—Alſo, a river of Ruſſia, which runs into the Angara, near Bratſkoi. N. lat. 56° 5′. E. long. 101° 40′.

OKAKEE, a town of America, in Virginia; 10 miles S.W. of Dumfries.

OKAMUNDEL, a circar of Hindooſtan, in Guzerat, on the S. ſide of the gulf of Cutch. The chief town is Nonagur.

OKANDA, a town of Japan, in the iſland of Niphon; 55 miles E. of Jedo.

OKANDE, a town of Ceylon, on the E. coaſt; 24 miles S. of Trincomaly.

OKASAKI, a town of Japan, in the iſland of Niphon. N. lat. 35° 40′. E. long. 138°.

OKE, an Egyptian weight, conſiſting of three rotolos, each of twelve ounces, at twelve drachms to the ounce, and ſixteen carats to the drachm.

OKEHAM, in *Geography*. See Oakham.

OKEHAMPTON. See Oakhampton.

OKEISUT, a cape on the W. coaſt of Weſt Greenland. N. lat. 61° 48′. W. long. 50° 3′.

OKELAS, in Egypt, and ſome other of the eaſtern countries, are a ſort of indifferent buildings round a court, and commonly appropriated to the merchants of ſome particular country, with their goods; as at Cairo, there is one for the merchants of Nubia, and the black ſlaves, and other goods they bring with them; and another for white ſlaves from Georgia.

OKER. See Ochre.

OKERAH, in *Geography*, a town of Bengal; 43 miles N.W. of Burdwan. N. lat. 23° 49′. E. long. 87° 20′.

OKI, an iſland of Japan, about 60 miles in circumference, near the N.W. coaſt of Niphon. N. lat. 35° 50′. E. long. 133° 30′.

OKIANOW, a town of the duchy of Warſaw; 20 miles N. of Warſaw.

OKILPOUR, a town of Hindooſtan, in Bengal; 20 miles S.E. of Mauldah.

OKLANDBEIG, a town of Norway, in the province of Aggerhuus, on the Glomme; eight miles S. of Chriſtiana.

OKLANSK, a town of Ruſſia, near the gulf of Penzinſkaia. N. lat. 63° 30′. E. long. 163° 44′.

OKMIANY, a town of Samogitia; 28 miles N. of Medniki.

OKNA, a town of European Turkey, in Moldavia; 44 miles S. of Niemecz.

OKOLSKI, in *Biography*, a Dominican, was a native of Ruſſia, and became provincial of his order in Poland in 1649. He publiſhed, in 1641, at Cracow, a work entitled "Orbis Polonus," in three volumes folio, being a hiſtory of the Poliſh nation, with learned reſearches concerning the origin of the Sarmatians. The work is very rare, and of high value. He was author alſo of a work entitled "Preco divini verbi Albertus epiſcopus Ratiſponenis."

OKONE, in *Geography*, a town of Eaſt Florida, on the Aſhley. N. lat. 50° 10′. W. long. 84° 16′.

OKOTSK. See Ochotsk.

OKOTSKOI, or Okhotskoi. See Ochotskoi.

OKRAH, a town of Hindooſtan, in the circar of Gurrah; 10 miles N. of Mahur.

OKSOR. See Acsor.

OKU-JESSO, ſignifying Upper Jeſſo, or North Jeſſo, an iſland on the coaſt of Tartary, ſeparated from Jeſſo by a ſtrait, and peopled by inhabitants who have the ſame origin with the Kuriles, though it lies 150 leagues to the weſtward of the Kurile iſlands. It is the ſame iſland with that which is called *Segalien* and *Tchoka*; which ſee.

OKULOKA, a town of Ruſſia, in the government of Archangel, on the river Pinega; 180 miles S.E. of Archangel.

OKUNEVO, an oſtrog of Ruſſia, in the government of Tobolſk, on the Eniſei or Yeniſei. N. lat. 69° 25′. E. long. 87° 24′.

OKUNEVSK, a town of Ruſſia, in the government of Tobolſk, on the Mijas; 200 miles S.W. of Tobolſk. N. lat. 55° 40′. E. long. 63° 54′.

OKUS, a bay on the W. coaſt of the iſland of Ximo, N. of Nangaſaki.

OLABUS, in *Ancient Geography*, a town of Aſia, in Meſopotamia, ſituated on the left bank of the Euphrates.

OLAF, in *Biography*, king of Norway in the 10th century, ſent miſſionaries into Greenland to convert the inhabitants of that country to Chriſtianity.

OLAHUS, Nicholas, a learned prelate, who flouriſhed in the 16th century, was born of an ancient family at Hermanſtadt in 1493. Being brought up to the eccleſiaſtical profeſſion he obtained various inſtances of preferment, till at length he was nominated by Ferdinand, king of Hungary, biſhop of Zagrat, and chancellor of the kingdom. He was afterwards elevated to the ſee of Agria, and in that character was preſent at the famous ſiege of that town by the Turks in 1552, in which he contributed greatly, by his liberality and exhortations, to the ſpirited and ſucceſsful defence made by the inhabitants. In 1553 he was appointed archbiſhop of Strigonia, and during the fifteen years in which he occupied this ſtation, he aſſiduouſly attended to the intereſts of religion and morality. He held two national councils at Tyrnau, the acts of which were printed at Vienna in 1560. It was chiefly through his munificence that the firſt Jeſuits' college in Hungary was founded at Tyrnau. In

1562 he was created palatine of the kingdom, in which quality he crowned Maximilian as king of Hungary. He died at Tyrnau in 1568: leaving behind him, as monuments of his induſtry and learning, "A Chronicle of his own Times:" "A Hiſtory of Attila," and "A Deſcription of Hungary."

OLAM, in *Geography*, a river which riſes in Thibet, and entering into the province of Chen-ſi, in China, changes its name into Tai-tong, and finally loſes itſelf in the Hoang. N. lat. 36° 10′. E. long. 102° 44′.

OLAND, a ſmall iſland of Denmark, in the North ſea; eight miles N. of Nordſtrand.

OLANE, in *Ancient Geography*, a town of Aſia, in the mountains of the Greater Armenia, and in the vicinity of Artaxata. Strabo.

OLANGO, in *Geography*, a ſmall iſland among the Philippines, near the E. coaſt of Siba. N. lat. 10° 33′. E. long. 123° 51′.

OLANOW, a town of Poland, in Volhynia; 28 miles S.W. of Berdiczow.

OLAN-POULAC, a town of Thibet; 75 miles N. of Haralope-pai.

OLARGUES, a town of France, in the department of the Herault, and chief place of a canton, in the diſtrict of St. Pons; ſeven miles N.E. of St. Pons. The place contains 1037, and the canton 9272 inhabitants, on a territory of 312½ kiliometres, in 12 communes. N. lat. 43° 33′. E. long. 3° 0′.

OLARTE, Fr. Diego de, in *Biography*, "was," ſays Mr. Southey, "a townſman and ſervant of Cortes, whom he accompanied to Mexico, and bore his ſhare in the guilt and the glory of that wonderful, but atrocious conqueſt. Olarte, however, enjoyed none of the ſpoils; and made the beſt atonement he could to the Mexicans, by entering the Franciſcan order, and living the life of a miſſionary among them forty years, inflicting upon himſelf during all that time penances, which proved the ſincerity of his contrition." He was one of the moſt ſucceſsful miſſionaries, and beſt loved by the natives. At different times he was guardian of the convent at Mexico, definidor of the province, and afterwards provincial. In 1567, the viſitors whom Philip II. ſent to proceed againſt the rebels, ordered him to Spain as a ſuſpected perſon; he cleared himſelf ſatisfactorily of the charge, and returned with the rank of comiſario-general of New Spain. But the fatigue of the voyage, and the anxiety which he had undergone, was too much for his old age, and he died ſhortly after his return in 1569.

OLASH, in *Geography*, a town of Aſiatic Turkey, in the government of Sivas; 10 miles S. of Sivas.

OLASSGUNGE, a town of Hindooſtan, in Bahar; 32 miles S. of Patna. N. lat. 25° 5′. E. long. 85° 20′.

OLAVIDES, the *Count de*, in *Biography*, was born in Spaniſh America, but had his education at Madrid, where he was ſecretary to the count de Aranda, whom he accompanied in his embaſſy to France. On his return to Spain Charles III. created him count, and appointed him to the office of ſuperintendant of Seville. He undertook the great work of fertilizing the Sierra Morena, or Black Mountain, a completely deſert region. By his perſeverance, and with the aid of the colonies of Germans which he carried thither, it aſſumed a new face. Notwithſtanding the benefits which he had thus rendered his country, he fell into diſgrace, and was ſent to priſon, from whence he effected his eſcape to Venice, where he died at the age of ſixty-five. A work entitled "El Evangelio en Triumf," or "The Triumph of the Goſpel," in four volumes, 4to. is attributed to him.

OLAX, in *Botany*, ſo called, as Linnæus, the author of the name informs us, from ωλαξ, *a furrow*, but how it applies to the plant we are not informed; nor is the difficulty of the queſtion leſſened by the name being ranged, in *Phil. Bot.* 184, among thoſe which allude to the medicinal effect of the plants that bear them.—Linn. Gen. 22. Schreb. 29. Willd. Sp. Pl. v. 1. 185. Vahl. Enum. v. 2. 33. Mart. Mill. Dict. v. 3. Brown. Prodr. Nov. Holl. v. 1. 357. Juſſ. 153. Gærtn. t. 179. (Fiſſilia; Juſſ. 260. Willd. Sp. Pl. v. 1. 194. Lamarck Illuſtr. t. 28. Spermaxyrum; Labillard. Nov. Holl. v. 2. 84.)—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Sapotæ*, Juſſ. *Santalaceis affine*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, hemiſpherical, undivided, entire, permanent. *Cor.* Petals ſix, combined in pairs by means of the fertile ſtamens, oblong, obtuſe, equal. *Stam.* Filaments three, alternate with, and combining the petals, ſhort; anthers heart-ſhaped erect; barren filaments ſix, longer, moſtly forked, one inſerted into the middle of each petal. *Piſt.* Germen ſuperior, roundiſh; ſtyle thread-ſhaped, ſhorter than the corolla; ſtigma obſcurely three-lobed. *Peric.* Drupa encloſed in the coloured calyx. *Seed* Nut cruſtaceous, of one cell.

Eſſ. Ch. Calyx undivided. Petals ſix, cohering in pairs by the ſtamens. Barren filaments ſix. Drupa inveſted with the enlarged calyx.

Obſ. The petals are, in ſome caſes, but five, and therefore vary in their degree or mode of connection. Mr. Brown obſerves that the New Holland ſpecies have the barren filaments ſimple, not forked, and only five petals, one of which is not connected with the reſt. The flowers are ſometimes polygamous.

1. O. *zeylanica*. Linn. Sp. Pl. 48.—Leaves ovate, pointed, ſmooth on both ſides. Branches angular.—Native of Ceylon. We received a ſpecimen from the late profeſſor Van Royen, but there is none in the Linnæan herbarium, nor do we find any figure of this ſpecies. The *branches* are ſmooth, long and wavy, obſcurely angular, of a tawny brown. *Leaves* alternate, on ſhort ſtalks, ovate, pointed, entire, wavy, ſmooth on both ſides, about two inches long, with one rib and ſeveral fine tranſverſe veins. *Flowers* in little axillary forked panicles, quite ſmooth in every part. Vahl deſcribes the leaves as nearly deſtitute of veins.

2. O. *ſcandens*. Roxb. Coromand. v. 2. 2. t. 102.—Leaves elliptical, obtuſe; downy beneath. Calyx minutely fringed.—Native of foreſts on the coaſts of Coromandel, flowering all the year round. *Trunk* inclining, often as thick as a man's thigh. *Branches* long, climbing, or trailing, round and downy when young. *Leaves* about the ſize of the laſt, but elliptical, two-ranked, ſoft and downy beneath, becoming ſmooth by age. *Flowers* in ſhort axillary cluſters, whitiſh ſmall. *Fruit* yellow, pulpy, inveſted with the enlarged, coloured, but ſcarcely pulpy, calyx.

3. O. *pſittacorum*. Vahl. Enum. v. 2. 33. (Fiſſilia pſittacorum; Lamarck Illuſtr. 102. t. 28.)—Leaves elliptic-lanceolate, very ſmooth. Branches round. Gathered by Commerſon in the iſle of Bourbon, and by Koenig in Ceylon. A buſhy *tree*, with round, ſmooth, rather zigzag branches. *Leaves* on very ſhort ſtalks, ſmooth and even, rather coriaceous, nearly two inches long. *Flowers* larger than in either of the foregoing. Vahl deſcribes five petals, one of which is unconnected with the reſt. The *drupa* is the ſize of a currant, partly covered by the apparently fleſhy calyx, not unlike the fruit of the Yew, at leaſt in ſhape.

4. O. *Phyllanthi*. Brown. n. 1. (Spermaxyrum Phyllanthi; Labill. Nov. Holl. v. 2. 84. t. 233.)—Leaves elliptical, emarginate. Stalks ſingle-flowered.—Native of the ſouth coaſt of New Holland. A *ſhrub* about ſix feet high, with

with numerous round branches. *Leaves* nearly ſeſſile, about half an inch long, of a broad elliptical figure, with a notch at the end, ſmooth. *Flowers* axillary, ſolitary, on ſimple ſtalks, ſhorter than the leaves, ſome male, others female, with a few united ones, all on the ſame plant. Labillardiere deſcribes the fruit as a *capſule*, burſting elaſtically towards the top, and inveſted with the calyx. The cracked *drupa* might, when dry, have the appearance of a capſule.

5. O. *ſtricta*. Brown n. 2.—"Leaves oblong-linear, with a ſmall point. Stalks ſingle-flowered."—Found near Port Jackſon, New South Wales.

6. O. *aphylla*. Br. n. 3.—"Leaves none. Spikes polygamous."—Gathered by Mr. Brown in the tropical part of New Holland.

OLAYOON, in *Geography*, a town of Hindooſtan, in the Carnatic; 15 miles S.E. of Tritchinopoly.

OLBA, in *Ancient Geography*, a town of Aſia, in Cilicia Trachea, or mountainous Cilicia, at a certain diſtance from the ſea, in the country called "Ketida," inhabited by the "Kennati," who were ſubject to the ſovereigns of Olba. Some medals of this ancient place inform us that Olba had the title of ἱερα, or ſacred; and that Polemon, one of the ſovereigns of Olba, took the name of Marc Antony, in honour of this Roman. It was in the year of Rome 713, that Aba received from Antony the principality of Olba, an epocha at which Antony and Cleopatra ſojourned in Cilicia. In proceſs of time the head of Auguſtus was found on ſome medals of Olba. The territory of Olba ſeems to have been both extenſive and fertile; it was watered by many ſtreams, and produced plenty of vines and fruit-trees. Under the lower empire Olba comprehended the province of Iſauria, and became an epiſcopal ſee; but from the time of Heraclius, it belonged to the diſtrict of Seleucia.

OLBASA, a town of Aſia, in Piſidia.—Alſo, a town of Antiochan Cappadocia. The name was alſo aſſigned to three towns in Aſia Minor.

OLBEGO, in *Geography*, a town of Spain, in Old Caſtile; 20 miles S. of Soria.

OLBERSDORF, the chief town of a lordſhip in Sileſia, in the principality of Jagerndorf; ſeven miles N.W. of Jagerndorf. N. lat. 50° 16′. E. long. 17° 44′.

OLBIA, in *Ancient Geography*, a maritime town on the E. coaſt of the iſland of Sardinia; with a port. It was built by the Greeks according to Pauſanias, and as Florus ſays, ravaged by Scipio.—Alſo, a town ſituated in the ſouthern part of Sardinia; built, ſays Livy, by Iolaus.—Alſo, a town of Gallia Narbonnenſis, on the ſea-coaſt; founded by the Marſilians, over-againſt the Stecades iſlands, where they kept a garriſon to guard againſt pirates.—Alſo, a town of Sarmatia, called Olbiopolis and Miletopolis, now "Kezikirman," ſituated at the confluence of the Hypanis and Boryſthenes. It was a colony of Mileſians.—Alſo, a town of Aſia, in Bithynia, called "Oliba," on the rivers of the Propontide.—Alſo, a town of Aſia, in Pamphylia, on the confines of Lycia.

OLBROM, in *Geography*, a town of Poland, in the palatinate of Cracow; 28 miles N.N.W. of Cracow.

OLBY, a town of France, in the department of the Puy de Dôme; nine miles W.S.W. of Clermont.

OLCADES, in *Ancient Geography*, a people who occupied the interior of Hither Spain; their territory was extenſive, and lay to the ſouth of the Carpetani.

OLD Age. See Age, and Longevity.

Old *Aſtronomy*. See Astronomy.

Old *Buffs*, in *Military Language*, a name given to the third regiment of foot. This regiment was put on the regular eſtabliſhment of the army in the year 1665, and denominated the "Buffs," from being the firſt whoſe accoutrements were made of leather prepared from the buffalo, after the manner of ſhamoy. The waiſtcoats, breeches, and facings of the coat were afterwards directed to be made of a correſponding colour. When other regiments aſſumed this part of their appointment, the third acquired the name of the "Old Buffs." This regiment has the privilege (and we believe excluſively) of marching through the city of London by beat of drum. Whether it derived this privilege from having exerted itſelf in the protection of the city, or from having, as has been vaguely reported, been at firſt compoſed of men who belonged to the train band, we cannot aſcertain. The uniform is red, with buff facings, buff waiſtcoats and breeches. The thirty-firſt regiment, which has the ſame uniform, is commonly called the "Young Buffs."

Old *Impoſition of Tonnage*. See Duty.

Old *Man's Beard*, in *Botany*. See Clematis.

Old *Milk*, in *Rural Economy*, a provincial word ſignifying ſkim-milk.

Old *Style*. See Style.

Old *Subſidy*. See Subsidy.

Old-*Wife Fiſh*, in *Ichthyology*, a name by which a ſpecies of baliſtes is called in ſeveral of our plantations. See Acarauna.

Old-*Wife* is alſo a name given to the wraſſe, a ſpecies of labrus.

Old *Works*, in *Mining*, are ſuch that are either fallen in or ſtand unwrought.

Old *Fort Bay*, in *Geography*, a bay on the S. coaſt of Canada, on the river St. Lawrence. N. lat. 51° 26′. W. long. 58°.—Alſo, a bay at the S. end of the iſland of St. Lucia.—Alſo, a cluſter of ſmall iſlands in the gulf of St. Lawrence. N. lat. 51° 20′. W. long. 57° 45′.

Old *Cape François*, forms the N. point of Coſbeck bay, on the N.E. part of the iſland of St. Domingo; five leagues E. of Cape de la Roche. N. lat. 19° 40′ 30″.

Old *Harbour*, a bay on the S. coaſt of Jamaica, W. of Port Royal, having many ſhoals and iſlands at its entrance.

Old *Head*, a cape on the S.E. coaſt of Ronaldſha, one of the Orkney iſlands. N. lat. 58° 37′. W. long. 2° 47′.

Old *Man*, a cape on the W. coaſt of Africa. S. lat. 14° 40′.

Old *Man's Bay*, a bay on the S. coaſt of Newfoundland; 80 miles E. of Cape Ray.

Old *Man's Creek*, a river of New Jerſey, which diſcharges itſelf into the Delaware, and ſeparates the counties of Salem and Glouceſter.

Old *Man's Port*, lies northward of Lima river, in Peru; eight or nine miles N. of Cadavayllo river.

Old *Nabb*, a cape of England, on the coaſt of Yorkſhire; nine miles N.W. of Whitby.

Old *Peak*, a cape of England, on the coaſt of Yorkſhire; nine miles N.N.W. of Scarborough.

Old *Road*, a town and harbour in the iſland of Antigua.

Old *Town*, a town of the ſtate of New York, on Staten iſland; 12 miles S.W. of New York.

Old *Road Town*, a town of the iſland of St. Chriſtopher, in a bay that has from five to fifteen fathoms of water near the ſhore; five miles W. of Baſſe Terre. N. lat. 17° 25′. W. long. 62° 48′.

Old *Town*, a town of the ſtate of Georgia; 16 miles S.S.E. of Louiſville.

Old *Town Creek*, a river of North Carolina, which runs into Cape Fear river. N. lat. 34° 8′. W. long. 78° 9′.

OLD *Town*, a town of Maryland, in Alleghany county, on the N. bank of Patomac river; 14 miles S.E. of Cumberland. N. lat. 39° 38′.—Alſo, a town of North Carolina, near Brunſwick.—Alſo, an Indian town, in one of the 54 iſlands reſerved by the Indians for their uſe in Penobſcot.

OLDCASTLE, *Sir* JOHN, in *Biography*, frequently denominated the good lord Cobham, was born in the reign of Edward III., and is ſaid to have been the firſt author, as well as the firſt martyr, among the Engliſh nobility. He obtained his peerage by marrying the heireſs of a lord Cobham who oppoſed the tyranny of Richard II. He was one of the leaders of the reforming party, and was at great expence in procuring and diſperſing copies of Wickliffe's writings among the people, as well as by maintaining a number of his diſciples as itinerant preachers. In the reign of Henry V. he was accuſed of hereſy, the growth of which was attributed to his influence. Being attached to the court, the king delayed his proſecution, that he might reaſon with him himſelf, but not being able to reclaim him to the church of Rome, he, in great diſpleaſure, reſigned him to its power. He was accordingly ſingled out as a proper victim of eccleſiaſtical ſeverity, whoſe puniſhment it was thought would ſtrike a terror into the whole party, and teach them they muſt expect no mercy. He was indicted at the inſtance of Arundel, archbiſhop of Canterbury, who, with the aſſiſtance of the biſhops of London, Wincheſter, and St. David's, condemned him to the flames, on account of his erroneous opinions. Lord Cobham, who was confined in the Tower, made his eſcape before the day appointed for his execution. He retired into Wales, where he lay concealed for four years. He formed, in his retreat, a plan to ſeize the king. Eltham was the place at which the plot was to be executed; Henry was apprized of the fact, and immediately removed to Weſtminſter; Cobham was not diſcouraged by the diſappointment, but changed the place of rendezvous to a field near St. Giles's. The king now had recourſe to offenſive meaſures, cauſed the gates of the city to be ſhut, to prevent any reinforcement of the Lollards, as they were denominated, from that quarter, came into the field in the night-time, ſeized ſuch conſpirators as appeared, and took priſoners many others whom he apprehended on their road. Cobham himſelf again made his eſcape, but was afterwards taken, when he was hanged as a traitor, and his body was burnt on the gibbet, in execution of the ſentence pronounced againſt him as a heretic. He wrote "Twelve Concluſions, addreſſed to the Parliament of England."

OLDCASTLE, in *Geography*, a ſmall poſt-town of the county of Meath, Ireland; 41 miles N.W. from Dublin.

OLDE, or HOLD, a town of Germany, in the biſhopric of Munſter; 20 miles S.E. of Munſter.

OLDEN, a town of Norway, in the province of Bergen; 95 miles N.N.E. of Bergen.

OLDENBROECK, a town of the duchy of Bremen, at the mouth of a ſmall river, which runs into the Elbe; 27 miles N.W. of Stade. N. lat. 53° 52′. E. long. 8° 39′.

OLDENBURG, HENRY, in *Biography*, a learned German in the ſeventeenth century, was deſcended from the counts of Aldenburg in Weſtphalia, and born in the duchy of Bremen, in Lower Saxony, about the year 1626. During the time of the Long parliament in the reign of Charles I. he came to this country in the character of conſul, a poſt which he continued to occupy under the adminiſtration of Cromwell. Afterwards he accepted the office of tutor to lord Henry O'Bryan, a young Iriſh nobleman, whom he attended to the univerſity of Oxford; and in 1656 he entered himſelf ſtudent in that univerſity, in order that he might have an opportunity of conſulting ſuch books as he wanted, chiefly in the Bodleian library. He was ſome time after this appointed tutor to lord William Cavendiſh, and became the intimate acquaintance and friend of the illuſtrious John Milton, who addreſſed to him four letters in his "Epiſtolæ Familiares." He was elected one of the earlieſt members of the Royal Society, and was afterwards choſen aſſiſtant ſecretary to Dr. Wilkins. No ſooner had he undertaken this office, than he applied himſelf to the ſeveral duties attached to his office with the utmoſt aſſiduity and zeal, and publiſhed the firſt number of the "Philoſophical Tranſactions." He eſtabliſhed a correſpondence with more than ſeventy perſons, in different parts of the world, on a vaſt variety of ſubjects. The method which he contrived to get through his buſineſs was to proceed in his work by the moſt ſimple mode; he never read a letter until he had before him, pen, ink, and paper, ready to anſwer it forthwith, ſo that the multitude of his letters never wearied him, nor ever lay heavy on his hands. He was the conſtant correſpondent of Mr. Robert Boyle, and tranſlated ſeveral of that philoſopher's works into the Latin language. In 1675 Mr. Oldenburg became involved in a diſpute with Mr. Hooke, who complained that juſtice had not been done him in the "Tranſactions," with reſpect to the invention of the ſpiral-ſpring for pocket watches. The diſcuſſion was terminated in favour of Mr. Oldenburg, by a declaration from the council of the Royal Society, "that the publiſher of the Tranſactions had carried himſelf faithfully and honeſtly in the managing the intelligence of the Royal Society, and given no cauſe for ſuch reflections." Mr. Oldenburg continued to publiſh the Philoſophical Tranſactions till the number 136, in the year 1677, after which the publication was diſcontinued, till it was reſumed by Dr. Nehemiah Grew. Mr. Oldenburg died in Auguſt 1678, at the age of fifty-two. He publiſhed numerous tracts, chiefly on theological ſubjects, and tranſlations of the "Prodromus to a Diſſertation concerning Solids naturally contained within Solids, &c. by Nicholas Steno:" of "A Genuine Explication of the Book of Revelations, &c. by A. B. Piganius;" and of "The Life of the Ducheſs of Mazarine."

OLDENBURG, in *Geography*, a county of Germany, bounded on the N. by the lordſhip of Jever, on the E. by the county of Delmenhorſt and the Weſer, on the S. by the biſhopric of Munſter, and on the W. by Eaſt Frieſland. This county meaſures 40 miles in length, and ſomewhat more than 30 in breadth, and belongs to the king of Denmark. The ſoil, generally fertile, affords excellent paſturage, and a good breed of horned cattle and horſes. It has, however, much moor-land, which is dug for good turf that is uſed for burning. Large and expenſive dykes and dams ſecure it againſt inundations. Amber has been found in ſome parts of it.—Alſo, the capital of the above county, ſeated on the Hunte, regularly fortified, and containing two churches. The citadel is the reſidence of a governor; 39 miles E.S.E. of Emden. N. lat. 53° 7′. E. long. 8° 15′.—Alſo, a town of Weſtphalia, in the biſhopric of Paderborn, with a fortified caſtle; 16 miles E.N.E. of Paderborn.

OLDENBURGER, PHILIP-ANDREW, in *Biography*, a juriſt and political writer, was ſettled at Geneva, where he taught law and hiſtory with much reputation. He wrote a great number of very learned works, ſeveral of which he publiſhed under borrowed names. One of theſe was Burgoldenſis, which was his real name reverſed with a little variation. The principal of theſe works are, 1. "Notitia Imperii, ſive Diſcurſus ad Inſtrumenta Pacis Oſnaburgo-Monaſterienſis:" this contains an uſeful liſt of the German

hiſtorians and writers on public law: 2. "Theſaurus Rerum publicarum totius Orbis," in four volumes 8vo., a work which, though imperfect, is uſeful, particularly for the knowledge of modern kingdoms. And 3. "Tractatus de Rebus publicis turbidis in tranquillum ſtatum reducendis." The author died at Geneva in the year 1678.

OLDENDORF, in *Geography*, a town of Weſtphalia, in the principality of Calenberg; 20 miles N.N.W. of Gottingen. N. lat. 51° 47'. E. long. 9° 41'.—Alſo, a town of Weſtphalia, in the county of Schauenburg, on the Weſer. N. lat. 52° 8'. E. long. 9° 20'.

OLDENLANDIA, in *Botany*, a name of Plumier's, in his Nova Genera 42. t. 36, was deſigned to commemorate Henry Bernard Oldenland, there called a German, but who it ſeems was really a Dane. Having imbibed a taſte for botany, under the tuition of Herman at Leyden, he undertook a voyage to the Cape of Good Hope, about the year 1695, for the purpoſe of collecting plants, where he ſoon after died, at an early age. His herbarium came at length into the hands of the Burmann family, and was taken to Upſal by the laſt profeſſor of that name, for the inſpection of Linnæus, who deſcribed from thence many of his Plantæ Africanæ Rariores, in the Amœn. Acad. v. 6.

The original *Oldenlandia* however proving the ſame genus with *Hedyotis*, and the latter name having obtained precedence, we ſhall eſtabliſh a new one, upon three ſpecies very erroneouſly referred to the former, their generic character being eſſentially different from HEDYOTIS; ſee that article, where we have already adverted to this ſubject.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Succulentæ*, Linn. *Saxifragæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of five equal leaves, permanent. *Cor.* Petals five, alternate with, and ſhorter than, the leaves of the calyx, concave, obtuſe. *Stam.* Filaments five, very ſhort, erect; anthers roundiſh. *Piſt.* Germen inferior, large, globoſe; ſtyles two, rarely but one, ſpreading, the length of the ſtamens; ſtigmas obtuſe. *Peric.* Capſule globoſe, coated, of two confluent cells, opening at the top. *Seeds* numerous, minute, inſerted on two flat orbicular vertical receptacles.

Eſſ. Ch. Calyx of five leaves. Petals five. Capſule inferior, of two cells, with many ſeeds.

Obſ. The parts of fructification are ſo minute, that our imperfect dried ſpecimens do not allow us to ſpeak with preciſion reſpecting the characters of this genus. It ſeems allied to *Vahlia*, but we rather wiſh to ſubmit our remarks to thoſe who may be able to examine the plants alive.

1. O. *dichotoma*. (O. pentandra; Retz. Obſ. faſc. 4. 22. Willd. Sp. Pl. v. 676. Heuchera dichotoma; Murray in Comm. Goett. for 1772 64. t. 1.)—Stalks two-flowered.—Native of the Eaſt Indies. *Root* annual? rather woody. *Stems* ſpreading, much branched, leafy, round, downy, a foot long. *Leaves* oppoſite, ſeſſile, linear, entire, roughiſh. *Flower-ſtalks* axillary, ſolitary, cloven, two-flowered. *Flowers* ſmall, yellowiſh. *Capſule* ſcarcely ſo large as a hemp-ſeed. *Style*, according to Retzius, ſolitary.

2. O. *ſeſſiliflora*. (O. digyna; Retz. Obſ. faſc. 4. 23. Willd. Sp. Pl. v. 1. 674.)—Flowers axillary, ſeſſile.—Found at Tranquebar, in rice-grounds, during the rainy ſeaſon. *Stems* procumbent, branched. *Leaves* ſeſſile, lanceolate, entire. *Flowers* nearly or quite ſeſſile; whether ſolitary or otherwiſe is not ſaid, and we have ſeen no authentic ſpecimen. *Petals* minute, white. *Styles* two.

3. O. *depreſſa*. Willd. Sp. Pl. v. 1. 675; excluding the citation of Rheede.—Leaves elliptical, ſtalked. Stalks axillary, in pairs, ſingle-flowered.—Native of the Eaſt Indies. *Stems* proſtrate, branched, ſmooth. *Leaves* like thoſe of *Thymus Serpyllum*, elliptical, obtuſe, ſmooth, without rib or veins, unequal, and ſomewhat heart-ſhaped at the baſe. *Calyx* ſmooth.

OLDENZEEL, in *Geography*, a town of Holland, in the department of Overiſſel, the capital of the country of Twente; 40 miles N.W. of Munſter. N. lat. 52° 24'. E. long. 6° 45'.

OLDESLOHE, a town of the duchy of Holſtein, which has ſalt-works; 15 miles W. of Lubeck. N. lat. 53° 50'. E. long. 10° 27'.

OLDHAM, JOHN, in *Biography*, an Engliſh poet of the ſeventeenth century, was born at Shipton, in Glouceſterſhire, in 1653, of which pariſh his father was miniſter. He was educated in grammar learning at Tetbury-ſchool, and in 1670 was entered at St. Edmund's hall, Oxford. After an abode of four years at the univerſity he became uſher of the free-ſchool at Croydon, where he remained three years. The Popiſh plot (ſee the article OATES) induced him to write his four ſatires againſt the Jeſuits. He had previouſly to this made himſelf known as a poet, by the compoſition of ſome pieces that were handed about in manuſcript. One or more of theſe had fallen into the way of the earls of Rocheſter and Dorſet, and ſir Charles Sedley, who were ſo much pleaſed, that they paid the author a viſit while in the humble ſituation at Croydon. Soon after this he removed to the ſeat of ſir Edward Thurland, as tutor to his grandſons. He afterwards undertook the tuition of a ſon of ſir William Hicks, and when he had fitted his pupil for foreign travel, he went to London to cultivate his connections among the poets and men of wit in that city. He was ſoon introduced to Dryden, and obtained the patronage of William, earl of Kingſton, who took him to his ſeat of Holme-Pierepont, where, in December 1683, he died of the ſmall-pox at the age of thirty. The noble earl erected a monument to his memory in the church of that place. His fame as a poet was chiefly obtained by his ſatires, the ſpirited and indignant vein of which gave him the appellation of the Engliſh Juvenal. They are, however, coarſe in their language, and harſh in their verſification, but poſſeſs much vigour of ſtyle and vivacity of deſcription. Of the poems of Oldham, part were publiſhed by himſelf, and the reſt after his death, under the title of "Remains." An edition of the whole, with the author's life, was given in two volumes. Biog. Brit.

OLDHAM, in *Geography*, a market-town and pariſh in the hundred of Salford, and county palatine of Lancaſter, England, is ſituated on a branch of the river Medlock, at the diſtance of ſix miles from Mancheſter. The ground, upon which the greater portion of the town is built, riſes conſiderably above the ſurrounding level, and has conſequently the advantage of commanding an extenſive proſpect. The chief trade here is in the manufacture of hats and of ſtrong fuſtians. Some cotton mills, however, have been eſtabliſhed; and as coals are abundant, the machinery is uſually put in motion by ſteam. The market of Oldham is only of recent conſtitution, as the town is entirely indebted for its preſent extent and importance to its proximity to, and connection with, Mancheſter, which may be regarded as the radiating focus of the cotton trade of this country. Oldham is a parochial chapelry, ſubordinate to Preſtwich, but has a church and a chapel belonging to the eſtabliſhment, beſides ſeveral diſſenting meeting-houſes. According to the population returns of 1811, this town contains 2843 houſes, and 16,930 inhabitants, being an increaſe of 4906 perſons ſince the population report of 1801 was taken. Aikin's Deſcription of the Country from thirty to forty Miles round Mancheſter,

cheſter, 1 vol. 4to. London, 1795. Beauties of England and Wales, vol. ix. by John Britton, F.S A.

OLDHEAD, or Old Head *of Kinſale*, a cape of Ireland, in the county of Cork, extending to the ſouth and weſt of Kinſale harbour. It was called by the Spaniards "Cabo de Velbo," and is very high and ſteep. N. lat. 51° 37'. W. long. 8° 30'.

OLDISLEBEN, a town of the principality of Weimar, ſeated on a hill near the Unſtrutt; 22 miles N. of Weimar.

OLDMIXON, John, in *Biography*, deſcended from an ancient family in Somerſetſhire, and flouriſhed in the 17th and 18th centuries; he was a violent opponent of the Stuart family, and in the reign of queen Anne attacked the writers of that period with ſo much violence, that Pope gave him a conſpicuous place in the Dunciad. His writings, at a ſubſequent period, obtained him a ſituation under government. He died in 1742. Beſides his fugitive and temporary pieces, he wrote "A Hiſtory of the Stuarts," in folio; "A Critical Hiſtory of England," in two vols. 8vo.; a volume of poems, and ſome dramatic pieces.

OLDNEY, in *Geography*, a ſmall iſland near the W. coaſt of Scotland. N. lat. 58° 12'. W. long. 5° 2'.

OLDYS, William, in *Biography*, an hiſtorical writer, was the natural ſon of Dr. Oldys, chancellor of Lincoln, and advocate of the court of admiralty. Having lived a diſſolute life, and expended what property had been left him, he became keeper of lord Oxford's library, of which he formed the catalogue when that collection was ſold by Oſborne the bookſeller. He was alſo employed to ſuperintend the publication of the Harleian miſcellany. The only public poſt he ever had was that of Norroy, king at arms. He died in 1761, at the age of 74. His principal works are the life of ſir Walter Raliegh; ſome articles in the General Hiſtorical Dictionary; thoſe in the Biographia Britannica ſigned G: the Britiſh Librarian: Introduction to Haywood's Britiſh Muſe, and the Life of Richard Carew, the antiquary.

OLEA, in *Botany*, the celebrated ελαια of the Greeks, whoſe value, on account of its oil, has rendered it famous throughout all antiquity. The word is derived from λειος, *ſmooth*, and alludes probably to the nature and qualities of the oil, for there is no remarkable ſmoothneſs about the plant, except indeed the upper ſurface of its leaves. Linn. Gen. 10. Schreb. 13. add. 816. Willd. Sp. Pl. v. 1. 44. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 21. Brown. Prodr. v. 1. 523. Michaux Boreal-Amer. v. 2. 222. Tournef. t. 370. Juſſ. 105. Lamarck Dict. v. 4. 537. Illuſtr. t. 8. Gærtn. t. 93.—Claſs and order, *Diandria Monogynia*. Nat. Ord. *Sepiariæ*, Linn. *Jaſmineæ*, Juſſ. *Oleinæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, ſmall, deciduous, its mouth four-toothed, erect. *Cor.* of one petal, funnel-ſhaped; tube cylindrical, the length of the calyx; limb flat, cloven into four, nearly ovate ſegments. *Stam.* Filaments two, oppoſite, awl-ſhaped, ſhort; anthers erect. *Piſt.* Germen ſuperior, roundiſh; ſtyle ſimple, very ſhort; ſtigma cloven, thickiſh, with emarginate ſegments. *Peric.* Drupa nearly ovate, ſmooth, of one cell. *Seed.* Nut ovato-oblong, rugoſe, generally two-celled.

Obſ. Some ſpecies are now removed from this genus, ſee Notelæa, while *Phillyrea* is by ſeveral botaniſts united to it. See Phillyrea.

Eſſ. Ch. Calyx cloven at the mouth into four, nearly ovate ſegments. Drupa ſuperior, ſingle-ſeeded.

1. O. *europæa*. Common Europæan Olive. Linn. Sp. Pl. 11. Fl. Græc. t. 3. Woodv. Med. Bot. t. 136.—Leaves lanceolate, entire, pale beneath. Cluſters axillary, denſe.—Native of the ſouth of Europe, and cultivated univerſally. It flowers from June to Auguſt. Rather a ſmall, evergreen *tree*, with ſquare, ſpreading, greyiſh *branches*. *Leaves* oppoſite, ſlightly ſtalked, acute, a little revolute, dark green above. *Cluſters* axillary, oppoſite, half as long as the leaves, hoary, on oppoſite, ſhort ſtalks. *Corollæ* white. *Drupa* elliptical, violet-coloured, bitter.

Five varieties of this ſpecies are enumerated in the *Hortus Kewenſis*, differing chiefly in the ſhape and direction of their leaves, and, in ſome meaſure, in the value of their fruit. This is unqueſtionably the original ſpecies of *Olea*, which has been held in all ages as the bounteous gift of Minerva to mankind. It has always been conſidered as emblematical of peace and plenty; indeed, it has been remarked, that the great quantity of oil which it produces in ſome countries, effectually realiſes the latter of theſe bleſſings. It is conjectured that the olive came originally from Aſia, being cultivated in moſt parts of Paleſtine, and having actually given a name to the celebrated mount near Jeruſalem.

2. O. *capenſis*. Cape Olive. Linn. Sp. Pl. 11. (Liguſtrum capenſe ſempervirens, folio craſſo ſubrotundo; Dill. Elth. 193. t. 160.)—Leaves ovate, entire. Cluſters panicled, divaricated.—Native of the Cape of Good Hope, flowering from June to September. A ſmall *tree*, or rather *ſhrub*, not much branched, with an erect, blackiſh-brown *trunk* beſet with aſh-coloured dots and lines. *Leaves* in pairs, decuſſated, ſometimes ſinuated at the end, paler underneath, with oblique, ſmooth veins. *Flowers* in axillary, panicled ſometimes pendent cluſters, ſmall and white. There is a variety of this ſpecies figured in Jacquin's Hort. Schoenb. v. 1. t. 2, under the name of *undulata*.

3. O *americana*. American Olive. Linn. Mant. 24. Willd. n. 3. (Liguſtrum lauri folio, fructu violaceo, baccis purpureis; Cateſb. Carol. v. 1. t. 61.)—Leaves elliptic-lanceolate.—Native of Carolina and Florida. It flowers in June. This ſpecies is remarkable for having male and female flowers as well as perfect ones on the ſame plant. It is an evergreen ſhrub, with oppoſite, entire, ſhining, ſtalked *leaves*. *Flowers* in ſhort, axillary, brachiated cluſters, with oppoſite ſtalks. *Nut* obovate, ſomewhat ſtriated, perforated at the baſe.

4. O. *excelſa*. Laurel-leaved Olive. Willd. n. 6. Vahl. Symb. v. 3. 3.—Leaves elliptical, acute. Bracteas perfoliate, the lower cup-ſhaped, permanent; upper large, deciduous.—Native of Madeira, flowering in May. This is a branched *tree* with an aſh-coloured, dotted *bark*. Leaves oppoſite and alternate, attenuated at each end, entire, ſmooth, coriaceous, veinleſs. *Flowers* in axillary, oppoſite, moſtly ſolitary, cluſters. *Corolla* twice as large as in the common olive.

5. O. *cernua*. Drooping Olive. Vahl. Symb. v. 3. 3. Willd. n. 4; excluding the ſynonym of Lamarck.—Leaves elliptic-lanceolate, very blunt. Cluſters axillary, ſimple. Flowers drooping. Tube of the corolla cylindrical.—Gathered in Madagaſcar by Commerſon, one of whoſe ſpecimens is before us. The bark of the young *branches* is of a glaucous grey. *Leaves* ſmaller and blunter than in the laſt. *Flowers* drooping; their tube about one-third of an inch long, cylindrical; limb in four ſpreading triangular ſegments, not half that length; the orifice bearded. *Stamens* four, which circumſtance, added to our ignorance of the *fruit*, renders the genus of this ſpecies at beſt very doubtful. Lamarck's t. 8. f. 2, quoted with heſitation in Willdenow, and perhaps in Vahl, whoſe third volume we have not at hand, is unqueſtionably a very different thing.

6. O. *fragrans*. Sweet-ſcented Olive. Thunb. Jap. 18.

t. 2. Willd. n. 7. Ait. n. 5. (Mokkſei; Kæmpf. Amœn. 844.)—Leaves elliptic-lanceolate, ſerrated. Flower-ſtalks ſimple, ſingle-flowered, axillary, many together.—Native of Cochinchina, China, and Japan, introduced into England in 1771. It is kept in the green-houſe or ſtove, flowering in ſummer, and is valuable for the peculiar and delicious ſcent of the little white *flowers*, which is like that of the higheſt-perfumed green tea. Hence ſuch tea has been reported to be ſcented with theſe flowers; but, as far as we can learn, without foundation. The Chineſe however are ſaid by Kæmpfer to eſteem them very much. The *leaves* of this plant are evergreen, ſhining, rather dark, finely and ſharply ſerrated. *Flowers* not bigger than ſome of the common kinds of *Galium*, pure white at firſt, but turning to a tawny-brown in decay. Thunberg ſpeaks of the *O. fragrans* as a very large tree in Japan. We have ſeen it ten or twelve feet high only, as yet, in England. If brought, while in flower, into an apartment, it will continue for ſome time to perfume the whole houſe, if regularly watered, and ſcreened from chilling blaſts of air.

Olea, in *Gardening*, contains plants of the exotic tree kind, as the olive-tree. The ſpecies cultivated are the common European olive (O. europæa); the Cape olive (O. capenſis); the American olive (O. americana); and the ſweet-ſcented olive (O. fragrans.)

Of the firſt ſort there are ſeveral varieties; as the warted-olive, which is a native of the Cape. The long-leaved, which is chiefly cultivated in the ſouth of France, and from which they make the beſt oil. The young fruit is moſt eſteemed when pickled.

And there are ſeveral ſub-varieties, as the broad-leaved, which is chiefly cultivated in Spain, where the trees grow to a much larger ſize than the preceding: the leaves are much larger, and not ſo white on their underſide; the fruit is near twice the ſize of the Provence olive, but of a ſtrong rank flavour, and the oil is likewiſe ſtrong.

There are alſo other varieties; as the narrow-leaved, ſhort hard-leaved, ſhining-leaved, African, Lucca, &c.

It may be obſerved, that the olive ſeldom becomes a large tree; but two or three ſtems frequently riſe from the ſame root, from twenty to thirty feet high, putting out branches almoſt their whole length, covered with a grey bark; the leaves are ſtiff, about two inches and a half long, and half an inch broad in the middle, gradually diminiſhing to both ends, of a lively green on their upper ſide and hoary on their under, ſtanding oppoſite; the flowers are produced in ſmall axillary bunches; they are ſmall, white, and have ſhort tubes ſpreading open at top; the firſt is a ſuperior-berried drupe, of an oblong ſpheroidal form, and of a yellowiſh-green colour, twining black when ripe.

Preparing the Oil.—The uſual method of making oil from olives in Italy is, to cruſh the fruit to a paſte with a perpendicular mill-ſtone running round a trough; which is then put into flat round baſkets, made of ruſhes, piled one upon another under the preſs; after the firſt preſſure, ſcalding water is poured into each baſket, its contents ſtirred up, and the operation repeated till no more oil can be ſkimmed off the ſurface of the tubs beneath; but this is not a good method; the oil is ſeldom pure, keeps ill, and ſoon grows rancid; but by another proceſs, which is that of pounding the fruit in a mortar, the cruſhed ſubſtance being then thrown into a long woollen bag, and rubbed hard upon a ſloping board, and then wrung, adding afterwards hot water, and continuing to preſs as long as a drop of oil can be drawn, the work is much more effectually performed. See Oil.

The difference in the kind of olive produces a difference in the oil; but concurring circumſtances occaſion other differences. If the olive be not ſufficiently ripe, the oil is better; if it be too ripe, the oil is thick and glutinous. The method of extracting the oil has alſo a very great influence on its quality. The oil-mills are not kept ſufficiently clean; the mill-ſtones, and all the utenſils, are impregnated with a rancid oil, which muſt inevitably communicate its flavour to the new oil. In ſome countries it is uſual to lay the olives in heaps, and ſuffer them to ferment before the oil is drawn. By this management the oil is bad; and this proceſs can only be uſed for oil that is intended for the lamp, or for the ſoap-boiler.

The unripe olives, when pickled, eſpecially the Provence and Lucca ſorts, are to many extremely grateful, and ſuppoſed to excite appetite and promote digeſtion. According to Miller, they are prepared by repeatedly ſteeping them in water; to which ſome add alkaline ſalt or quick lime, in order to ſhorten the proceſs; after which they are waſhed, and preſerved in a pickle of common ſalt and water, with ſometimes the addition of an aromatic.

In ſome places, ſays Chaptal, they are macerated in boiling water, charged with ſalt and aromatics; and, after 24 hours digeſtion, they are ſteeped in clear water, which is renewed till their taſte is perfectly mild. Sometimes nothing more is done than to macerate the olives in cold water; but they are frequently macerated in a lixivium of quick-lime and wood-aſhes, after which they are waſhed in clear water. But in whatever manner the preparation is made, they are preſerved in a pickle charged with ſome aromatic plant, ſuch as coriander and fennel. Some perſons preſerve them whole, others ſplit them, for the more complete extraction of their mucilage, and in order that they may be more perfectly impregnated with the aromatics. All theſe proceſſes evidently tend to extract the mucilaginous principle, which is ſoluble in water, and by theſe means to preſerve the fruit from fermentation. When the operation is not well performed, the olives ferment and change. If olives be treated with boiling water, to extract the mucilage, before they are ſubmitted to the preſs, a fine oil will be obtained, without danger of rancidity. When the oil is made, if it be ſtrongly agitated in water, the mucilaginous principle is diſengaged; and the oil may be afterwards preſerved for a long time without change. Chaptal ſays, that he has preſerved the oil of the marc of olives, prepared in this manner, for ſeveral years, in open bottles, without any alteration. Chaptal's El. of Chem. vol. iii.

It is ſaid, that when the olives are put into thoſe ſmall barrels, in which they are brought to us, they give them a flavour by throwing over them an eſſence uſually compoſed of cloves, cinnamon, coriander, and fennel. But this eſſence is a kind of ſecret with thoſe who deal in them; and it is in this that the whole difficulty of the preparation is ſaid to conſiſt.

The beſt ſalad oil is of a bright pale amber colour, bland to the taſte, and without the leaſt ſmell.

It has been obſerved, that with a little protection in ſevere froſt, the olive-tree may be maintained againſt a wall about London, but that in Devonſhire there are ſome of theſe trees which have grown in the open air many years, and are ſeldom injured by froſt, yet the ſummers are not warm enough to bring the fruit to any great perfection.

Method of Culture.—In Languedoc and Provence, where the olive-tree is greatly cultivated, they propagate it by truncheons, ſplit from the roots of the trees; for as theſe trees are frequently hurt by hard froſts in winter, ſo when the tops are killed, they ſend up ſeveral ſtalks from the root; and when theſe are grown pretty ſtrong, they ſeparate them with an axe from the root; in the doing of which they

are

are careful to preſerve a few roots to the truncheons; theſe are cut off in the ſpring after the danger of the froſt is over, and planted about two feet deep in the ground, covering the ſurface with litter or mulch, to prevent the ſun and wind from penetrating and drying the ground; when the plants have taken new root, they are careful to ſtir the ground, and deſtroy the weeds.

Theſe trees will grow in almoſt any ſoil, but when they are planted in rich moiſt ground, they grow larger and make a finer appearance than in poor land; but the fruit is of leſs eſteem, becauſe the oil made from it is not ſo good as that which is produced in a leaner ſoil. The chalky ground is eſteemed the beſt for theſe trees, and the oil which is made from the trees growing in that ſort of land is much finer, and will keep longer than the other.

In the countries where the inhabitants are curious in the making of their oil, they are frequently obliged to get truncheons of the ordinary ſorts of olives to plant; but after they have taken good root, they graft them with that ſort of olive which they prefer to the others. In Languedoc, they chiefly propagate the cormeau, the ampoulan, and moureau, which are three varieties of the firſt ſpecies, or Provence olive with a ſmaller oblong fruit; but in Spain the ſecond ſort, or Spaniſh olive with the largeſt fruit, is generally cultivated, where they have more regard to the ſize of the fruit, and the quantity of oil they will produce, than to their quality.

Theſe plants may be propagated in this climate by layers, which ſhould be made from the young branches in the ſpring, in the uſual manner, and be occaſionally watered during the ſummer ſeaſon, when in the autumn following they may be taken off and be planted in ſeparate pots, being duly watered and placed in proper ſhade till freſh rooted, removing them in the beginning of the autumn into the ſhelter of the greenhouſe. The layers ſometimes, however, require two ſummers before they become perfectly rooted. But it is, notwithſtanding, the beſt method to purchaſe plants of this ſort, which are annually ſent to the Italian warehouſemen in London, of pretty large ſizes, with orange and other trees, as they are very tedious in raiſing from layers.

Theſe plants, after being thus procured, and cleaned from filth by ſoaking their roots in water, ſhould be planted in pots filled with freſh ſandy light earth, plunging them in a moderate hot-bed, ſhading them in the hot ſun, and refreſhing them occaſionally with ſlight waterings as the earth in the pots becomes dry. When they begin to ſhoot they ſhould have air admitted pretty freely in proportion to the weather, being afterwards inured to the open air in a place defended from winds, removing them in the beginning of autumn into the green-houſe. And after they have in this management acquired ſtrong roots, they may be removed with earth about them, and be planted out in the open ground in a dry warm ſituation, being managed as myrtles and other ſimilar plants. When covered by mats in the winter froſt, great care muſt be taken to prevent their becoming mouldy, by not letting them remain covered too long, without the air being admitted.

They flower and produce fruit ſometimes in two or three years.

Theſe plants all afford variety among others of the greenhouſe kind, as well as in other ſituations.

Olea is alſo the name of a ſtone deſcribed by Ludovicus Dulcis, and ſome other ſuch authors, who attribute great virtues to it, and ſay it was variegated with ſeveral colours, as yellow, black, white, green, &c. It ſeems to have been ſome one of the common agates, to which their ignorance had prompted them to give a new name.

OLEAGINOUS, ſomething that partakes of the nature of oil; or out of which oil may be expreſſed.

Thus olives, nuts, almonds, &c. are oleaginous fruits, or fruits out of which oil is expreſſed.

Pines, firs, &c. are oleaginous woods, yielding reſin, turpentine, &c. Of all woods, oleaginous ones burn the beſt.

OLEANDER, or Rose-bay, in *Botany*. See Nerium.

OLEARIUM, in *Natural Hiſtory*, a ſpecies of *Buccinum*.—Alſo, a ſpecies of *Murex*; which ſee.

OLEARIUS, a ſpecies of *Turbo*; which ſee.

Olearius, Adam, in *Biography*, a learned German, was born in 1603, at Aſherleben, in Lower Saxony. He was for ſome time a profeſſor at Leipzic, which office he quitted for a place in the ſervice of Frederic, duke of Holſtein-Gottorp. The prince had a plan of bringing a ſhare of the commerce of the Levant to his new town of Frederickſtadt, and for that purpoſe ſent an embaſſy to the czar of Muſcovy, and the king of Perſia, which embaſſy Olearius joined in the quality of ſecretary and counſellor. The miſſion continued ſix years, *viz.* from 1633 to 1639; and Olearius drew up an account of the journey in the German language, printed at Sleſwick in 1656 and 1671, accompanied with figures deſigned by himſelf. It is a curious and highly eſteemed work, and has been tranſlated into ſeveral languages. Upon his return, Olearius took up his reſidence at Gottorp, and was appointed librarian, antiquary, and mathematician to the duke. He died in 1671. He was very learned in mathematics; a ſkilful muſician; and a proficient in the oriental languages, eſpecially in the Perſian. He was author of many other works, as "The Valley of Perſian Roſes, a Collection of pleaſant Stories, ingenious Sayings, and uſeful Maxims, by the Poet Shach-Saadi, tranſlated into German;" "A Narrative of a Voyage to the Indies, by Albert de Mandeſlo, with Remarks;" "An abridged Chronicle of Holſtein, from 1448 to 1663;" "The Gottorp Cabinet of Curioſities." Moreri.

Olearius, Godfrey, a learned German Lutheran divine in the ſeventeenth century, was born at Halle, in Saxony, in the year 1604. He was educated for the church, and became paſtor of St. Ulric's church, in his native city. After this he was created doctor of divinity, appointed paſtor of St. Mary's, and was nominated ſuperior and inſpector of the Lutheran Gymnaſium; and finally made ſuperintendant of the churches in the duchy of Magdeburg by the elector of Brandenburg. He died in 1685, at the age of eighty-one. He was author of ſeveral theological works, among which were "A Life of Chriſt, from the four Evangeliſts;" and "An Explication of the Book of Job." Moreri.

Olearius, Godfrey, grandſon of the laſt, was born at Leipſic in the year 1672. When he had completed his academical courſe he went to Holland, and from thence to England, for farther improvement. Upon his return to Leipſic in 1699, he obtained a profeſſorſhip of the Greek and Latin languages; an office which he filled with diſtinguiſhed ability till the year 1708, when he was appointed to the theological chair. He obtained other conſiderable offices, and died in 1715, leaving behind him many works that teſtify to his induſtry and talents; among theſe were "An Introduction to the Roman and German Hiſtories;" a Latin verſion of "The Hiſtory of the Apoſtles' Creed," from the Engliſh of ſir Peter King; a Latin verſion of "Stanley's Hiſtory of Philoſophy," and ſeveral theological works of conſiderable merit. The father of this perſon, *viz.* John Olearius, was born at Halle in 1639; was alſo diſtinguiſhed for his literary acquirements, and was one of the firſt who engaged with Carpzovius, Alberti, and Ittigius

gius in furniſhing contributions to the "Leipſic Acts." He was created doctor of divinity, and was ten times raiſed to the dignity of rector. He died in 1713. Moreri.

O'LEARY, Arthur, an eminent Catholic prieſt of the laſt century, was born in the city of Cork. He was ſent to France at an early age, and purſued his ſtudies at the college of St. Malo's in Britanny, after which he entered into the Franciſcan order of Capuchins. When he had finiſhed his ſtudies, he was appointed chaplain to a regiment of his countrymen in the ſervice of the French king, an office which he ſoon gave up, and returned to his native country. By the aſſiſtance of ſome friends he built a ſmall chapel in his native city, in which he officiated. While employed in the duties of his profeſſion, he combated a work at that time publiſhed in Cork, entitled "Thoughts on Nature and Religion," and with the leave of the biſhop of his dioceſe, he publiſhed a piece in juſtification of his own creed, in oppoſition to the dogmas of his antagoniſt, entitled "A Defence of the Divinity of Chriſt, and the Immortality of the Soul." Shortly after this, when the parliament of Ireland ſhewed a diſpoſition to relax the rigour of the penal laws againſt the Roman Catholics, and framed a ſort of teſt oath, to be adminiſtered to ſuch of them as ſhould claim the benefit of acts paſſed in their favour in the year 1782, many perſons heſitated about the propriety of taking it. On this occaſion Mr. O'Leary publiſhed a tract entitled "Loyalty aſſerted, or the Teſt-oath vindicated," in which he explained the ſeeming difficulties that occurred ſo much to the ſatisfaction of his Catholic countrymen, that they almoſt unanimouſly complied with the proviſion of the legiſlature. Theſe publications were highly applauded, and obtained for the author many friends among the liberal and enlightened, but at the ſame time they excited againſt him the envy and jealouſy of prieſts, who poſſeſſed neither the ſpirit nor the talent to act in the ſame manner. He enjoyed his triumph, and having ſhewn that the Roman Catholics of Ireland might, conſiſtently with their religion, ſwear that the pope poſſeſſed no temporal authority or juriſdiction in that kingdom, he became the favourite and friend of almoſt all the eminent Iriſh political and literary characters. At this critical period, when the combined fleets of France and Spain inſulted the Britiſh coaſt, and threatened an invaſion of Ireland, he addreſſed his Catholic countrymen in the moſt energetic language, in the cauſe of order and loyalty, and with ſuch effect as to merit the thanks of the government. He was equally ſucceſsful, not only in quelling thoſe inſurgents who had attacked the tythe-proctors of the Proteſtant clergy, but in bringing them to a ſenſe of their miſconduct. This occaſioned an attack upon himſelf from Dr. Woodward, the Proteſtant biſhop of Cloyne, which he repelled in "A Defence of the Conduct and Writings of the Rev. Arthur O'Leary, &c. written by himſelf, in Anſwer to the ill-grounded Inſinuations of the Right Rev. Dr. Woodward." This defence, publiſhed in 1788, is a maſter-piece of wit, argument, irony, and energetic writing, and yet was drawn up in leſs than eight hours. His antagoniſt on this occaſion acknowledged, that O'Leary repreſents matters "ſtrongly and eloquently," and that, "Shakſpeare-like, he is well acquainted with the human heart." Soon after this he left Ireland, and came to London, where he reſided for many years as principal miniſter of the Roman Catholic chapel in Soho-ſquare: here he was highly eſteemed, and extremely well attended by perſons of his own perſuaſion. In this place he pronounced, in the year 1800, a funeral oration on pope Pius VI., before a vaſt concourſe of Engliſh nobility, and foreigners of high rank. He died at an advanced age in the month of January 1802, and was attended to his grave at St. Pancras church by many thouſands of the Catholics, by whom he was highly reſpected, as well for his ardent piety as for his impreſſive manner as a preacher. As a writer, his ſtyle is fluent, bold, and figurative, but deficient in grace, perſpicuity, and ſometimes grammar. His higheſt praiſe, however, ariſes from his having been a diſtinguiſhed friend to freedom, on which account he was frequently complimented by Meſſrs. Grattan, Flood, and other diſtinguiſhed members of the Iriſh parliament, in their public ſpeeches. He was author of many works beſides thoſe already referred to. His "Miſcellaneous Tracts" form one volume 8vo. For farther particulars, the reader may conſult the Monthly Magazine for March 1802.

OLEASTER, Jerome, a learned Portugueſe monk, who flouriſhed in the ſixteenth century, was probably a native of Azambuja, a town on the banks of the Tagus. In the year 1520, he took the habit of the Dominican order in a monaſtery at Liſbon, and ſoon acquired the character of an excellent philoſopher, a ſound divine, and a perfect maſter of the Latin, Greek, and Hebrew languages. Above all, he had the reputation of being moſt intimately converſant with the ſacred ſcriptures. In 1545 he was one of the divines whom John III. king of Portugal, ſent to aſſiſt on his behalf at the council of Trent. Upon his return, he was nominated biſhop of St. Thomas' in Africa, but he declined accepting that dignity. He was afterwards appointed to the office of "Inquiſitor," and filled the various offices of truſt and honour in that province of his order. He died in the year 1563. He was author of "Commentaries" on many parts of the ſcriptures, but the work by which he is chiefly known is entitled "Hieronymi ab Oleaſtro Commentarii in Pentateuchum," which was publiſhed in the years 1556—8, in five parts, forming together a folio volume. This edition is very rare, and much ſought after by collectors, owing to the circumſtance of its not having been ſubjected to the examination of the inquiſitorial office. It has paſſed through ſeveral other editions. His Commentary on Iſaiah was firſt publiſhed at Paris in 1623. Moreri and Gen. Biog.

Oleaster, in the *Materia Medica*, the name of the ſallow thorn, or ſea buckthorn, the rhamnoides ſalicis folio of botanical authors.

OLEASTRUM, in *Ancient Geography*, a town of Spain, on the route from Tarragona to Tortoſa; ſituated on the ſea-coaſt, in the country of the Coretani, S.W. of Tarraco.

OLECRANON, in *Anatomy*, a proceſs of the ulna, which forms the prominence of the elbow. See Extremities.

Olecranon, *Fractures of*. See Fractures.

OLEFIANT Gas. This is an inflammable gas, compoſed of carbon and hydrogen. It burns with a brilliant flame. This gas is formed during the burning of wax and ſpermaceti oil, which accounts for the brilliant light afforded by thoſe combuſtible bodies. When we recollect the great denſity of this gas, we are not ſurpriſed at its brilliant flame. Although only one-ſixth of it is hydrogen, yet that is as condenſed as to give a light, the denſity of which is to that of hydrogen as 12.5.

Mr. Dalton has determined the weight of the atom of this gas to be 6.4, being an atom of carbon 5.4 with an atom of hydrogen 1. See *Olefiant Gas* under Carbon, and Gas.

OLEGOU, in *Geography*, a cape of Ruſſia, in the ſea of Ochotſk; 252 miles E. of Ochotſk. N. lat. 59° 20'. E. long. 151° 14'.

OLEINÆ, in *Botany*, a natural order of plants, ſeparated by Mr. R. Brown, after Hoffmanſegg and Link, from the

the *Jaſmineæ* of Juſſieu, and including *Chionanthus, Olea, Phillyrea* (by ſome united to *Olea*) and *Notelæa*. We do not ſee the grounds of the above ſeparation. See JASMINEÆ and NOTELÆA.

OLEKMA, in *Geography*, a river of Ruſſia, which riſes in the mountains on the frontiers of China, in N. lat. 49°, and flowing due north, enters the Lena, oppoſite to Olekminſk.

OLEKMINSK, a town of Ruſſia, on the Lena, at its junction with the Olekma, in the government of Irkutſk. N. lat. 60° 25′. E. long. 119° 14′.

OLEN, in *Biography*. See OLENUS.

OLENEI, in *Geography*, a cape of Ruſſia, at the W. ſide of the mouth of the Obſkaia gulf, in the Karſkoi ſea. N. lat. 72° 15′. E. long. 72° 22′.

OLENEI *Nos*, a cape of Ruſſia, in the White ſea; 60 miles N. of Archangel.

OLENEK, a town of Ruſſia, at the mouth of the river Olenek, near the Frozen ocean. N. lat. 72° 24′. E. long. 114° 14′.—Alſo, a river of Ruſſia, which riſes in N. lat. 67° 20′, and runs into the Icy ſea, N. lat. 72° 30′. E. long. 104° 14′.

OLENI, a town of Poland, in the palatinate of Braclaw; 52 miles N.W. of Braclaw.

OLENKA, a river of Ruſſia, which runs into the Tungunſka, N. lat. 58° 6′. E. long. 95° 14′.—Alſo, a river of Ruſſia, which runs into the Vitim, N. lat. 55° 30′. E. long. 115° 54′.

OLENOS, in *Ancient Geography*, a town of Achaia, towards the N.W. near the mouth of the river Melas; ſuppoſed to be the preſent "Caminitza."

OLENSKOI, in *Geography*, a town of Ruſſia, in the government of Archangel, on the Vokſcha; 120 miles E. of Archangel.

OLENUM, in *Ancient Geography*, a town of Peloponneſus, in Achaia, between Patræ and Dyme.

OLENUS, in *Biography*, a Greek poet, older than Orpheus, came from Xanthe, a city of Lycia. He compoſed ſeveral hymns, which were ſung in the temple of Delos upon feſtival days. Olenus has the reputation of being one of the founders of the oracle at Delphi, and he is ſaid to have been the firſt who filled, at that place, the office of prieſt of Apollo, and to have given reſponſes in verſe.

OLEOSUM *Sal Volatile*. See SAL.

OLEOUT, in *Geography*, a river of America, in New York, which runs into the E. branch of the Suſquehannah.

OLERON, a town of France, in the department of the Lower Pyrenees, and chief place of a diſtrict; 10 miles W. of Tarbe. The place contains 5158, and the canton 13,977 inhabitants, on a territory of 140 kiliometres, in 19 communes. N. lat. 42° 10′. W. long. 0° 32′.—Alſo, a town of France, in the department of the Lower Charente, on the E. coaſt of the iſland of Oleron; 15 miles S. of La Rochelle. N. lat. 45° 33′. W. long. 1° 6′.—Alſo, an iſland in the Atlantic, near the W. coaſt of France, 5½ leagues long and from one to two wide; ſeparated from the continent by a narrow channel, called "Pertuis de Maubuſſon," and from the iſland of Ré by the "Pertuis de Antioche." The inhabitants, eſtimated at 12,000, are diſtributed in the town of Oleron and ſeveral villages. The ſoil is fertile; but moſt of the occupiers are ſeamen. It was formerly in the poſſeſſion of the crown of England, and has been famous for the laws mentioned in the next article. N. lat. 45° 46′. W. long. 1° 11′.

OLERON, *Laws of*. The inhabitants of the iſland of Oleron have been able mariners for ſeven or eight hundred years paſt; ſo that they framed and drew up the laws of the navy or marine, which are ſtill called the laws of Oleron. According to the French writers theſe maritime laws were digeſted in the fore-mentioned iſland under the title of "Reole des jugemens d'Oleron," by direction of queen Eleanor, the wife of Henry II., in her quality of ducheſs of Guienne, and afterwards enlarged and improved by her ſon Richard I. But Selden (De Dominio Maris, c. 14.) denies this, and maintains that theſe laws were compiled and promulgated by Richard I., as king of England. See USES *and cuſtoms of the ſea*.

Theſe laws, being accounted the moſt excellent ſea-laws in the world, are recorded in the Black Book of the Admiralty.

OLES, in *Geography*, a town of Iſtria; 16 miles N.W. of Pedena.

OLESA, a town of Spain, in the province of Catalonia; 16 miles N.W. of Barcelona.

OLESKO, a town of Poland, in the palatinate of Belcz; 36 miles S.E. of Belcz.

OLESNICK, a town of Poland, in the palatinate of Sandomirz; 28 miles W. of Sandomirz.

OLETTA, a town of the iſland of Corſica; 6 miles S.W. of Baſtia. N. lat. 42° 33′. E. long. 9° 30′.

OLETTE, a town of France, in the department of the Eaſt Pyrenees, and chief place of a canton, in the diſtrict of Prades; 7 miles S.W. of Prades; celebrated for its warm baths. The place contains 1000, and the canton 5361 inhabitants, on a territory of 385 kiliometres, in 24 communes.

OLEVITO, LA, a town of Naples, in Principato Citra; 23 miles E. of Salerno.

OLEUM, OIL. See OIL.

OLEUM *Medicum*, in the *Writings of the Ancients*, a name given to a famous oil which had a quality of burning under water, in ſpite of all that could be done to quench it. It was called *Medicum*, becauſe of its being produced among the Medes, and ſome have called it *oleum Medeæ*, becauſe it was ſuppoſed to be that ſubſtance with which Medæa anointed the crown of her rival. Ammianus Marcellinus tells us, that if an arrow was anointed with this oil, and ſhot out of a bow againſt any inflammable ſubſtance, the whole immediately took fire, and, if any one attempted to quench the flames by water, they only burnt the more fiercely for it. The *venenum Pharicum* of Nicander is ſuppoſed to be the ſame with this oil.

OLEUM *Medeæ*, a name given by the ancients to the mineral fluid, more generally known by that of *naphtha*.

OLEUM *Vitri Antimonii*, in *Medicine*, a name given by Baſil Valentine, and others, to a famous preparation of antimony, which they keep as a ſecret, or at leaſt declare in ſuch terms as are unintelligible, and boaſt of, as the univerſal medicine. The learned Kerkring has given the proceſs for making this red oil of the glaſs of antimony, but that in ſo enigmatical a manner, that he ſeems himſelf not to expect any body to underſtand him; and only ſays, in his own juſtification, that he has given it in plainer terms than any body had done before him. The author relates many wonderful things of this diaphoretic oil, on his own experience; particularly, the curing a confirmed dropſy, by throwing off the water by ſweat; ſo that the patient, in a manner, ſwam in it, and the drops run through the bed, in all parts, to the floor. It were well if we could underſtand the proceſs.

OLEWSKO, in *Geography*, a town of Poland, in the palatinate of Brzeſc; 88 miles E.S.E. of Pinſk.

Strahan and Preſton,
New-Street Square, London.

OLFACTORIUS NERVUS, in *Anatomy*, the nerve of the firſt pair, which is diſtributed in the noſe, and in which the ſenſe of ſmelling reſides. See NERVE.

OLGSKOI, in *Geography*, a town of Ruſſia, in the government of Olonetz, ſeated on the Latcha lake; 12 miles S. of Ka-gopol.

OLHOH, a town of Arabia, in the province of Hedſjas; 66 miles S.S.E. of Mecca.

OLIANA, a town of Spain, in the province of Catalonia; 7 miles N.W. of Solſona.

OLIAPOUR, a town of Bengal, capital of the circar of Baharbund; 195 miles N.N.E. of Calcutta. N. lat. 25° 22′. E. long. 89° 42′.—Alſo, a town of Hindooſtan, in Dowlatabad; 20 miles N.W. of Darore.

OLIAROS, in *Ancient Geography*, a ſmall iſland in the number of the Cyclades, ſituated near to and W. of Paros, ſaid to be a colony of Sidonians.

OLIAS, in *Geography*, a ſmall, but very agreeable, town of Spain, on the road from Madrid to Toledo, two leagues from the latter place. It is the only place in this route which affords any fruit-bearing trees.

OLIBA, in *Ancient Geography*, a town of Spain, in the Tarragonenſis, and in the country of the Bærones.

OLIBANUM, in *Pharmacy*, a kind of gum reſin, uſually called *male* FRANKINCENSE; which ſee.

It has its name *olibanum, quaſi oleum Libani;* becauſe diſtilled in form of an oil, from the bark of a tree growing on mount Lebanon: the *Juniperus Lycia*. It is collected chiefly in Arabia, and imported in cheſts and caſks from the Levant. Its ſpecific gravity is 1.173. Diſtilled alone it affords a volatile oil; but in conjunction with water or alcohol no oil comes over. Alcohol diſſolves three-fourths of it: after trituration with water and depoſition of the reſinous matter, three-eighths remain diſſolved: ether takes up more than one-half, leaving after evaporation in water a very pure tranſparent reſin; and the undiſſolved part, becoming white and opaque, is almoſt entirely ſoluble in water, forming a milky ſolution. Hence olibanum appears to conſiſt of reſin, gum, and a volatile oil. For its other properties and uſes, ſee FRANKINCENSE.

OLIBATO, or LIBATTA, in *Geography*, a river of Africa, which runs into the ſea, E. of Cape Lopez Gonſalvo, forming a bay at its mouth. This river is ſaid to abound with crocodiles.—Alſo, a town of Africa, in Lower Guinea, on the above-named river, containing about 300 houſes; 36 miles E. of Cape Lopez Gonſalvo. S. lat. 1°. E. long. 10° 54′.

OLICANA, in *Ancient Geography*, a town of the iſle of Albion, in the country of the Brigantes, which was ſituated at Ilkley, on the river Wherſe, in Yorkſhire.

OLIFANT's, OLIPHANT's, or *Elephant River*, a river of Africa, on the weſtern coaſt of the Cape of Good Hope, which, after collecting the ſtreamlets of the firſt chain of mountains in its northerly courſe along their feet, diſcharges itſelf into the Southern Atlantic, S. lat. 31° 30′. The navigation of this river is impeded by a reef of rocks acroſs its mouth. Olifant's river, which is a fine clear ſtream, flowing through a narrow valley, hemmed in between the great chain of mountains and an inferior ridge called the "Cardouw," forms one of the diviſions of the diſtrict of Stellenboſch and Drakenſtein. This valley, being interſected by numerous rills of water from the mountains on each ſide, is extremely rich and fertile; but the great diſtance from the Cape, and the bad roads over the Cardouw, preſent little encouragement for the farmer extending the cultivation of grain, fruit, or wine, beyond the neceſſary ſupply of his own family. Dried fruit is the principal article they ſend to the market, after the ſupplies which they furniſh, of horſes, horned cattle, and ſheep. The country on each ſide of the lower part of the river is dry and barren, and for many miles from the mouth entirely uninhabited. A chalybeate ſpring of hot water, of the temperature of 108° of Fahrenheit's ſcale, flows in a conſiderable ſtream out of the Cardouw mountain into the Olifant's river; and a bathing-houſe is erected over the ſpring. All the ſmaller kinds of antelopes, jackalls, hares, and partridges are very abundant in this and the adjoining diviſions of Stellenboſch and Drakenſtein. Barrow's Africa, vol. ii.

OLIGACTIS, in *Natural Hiſtory*, a name given by Linnæus, and others, to a genus of ſtar-fiſh, conſiſting of thoſe which have fewer than five rays.

OLIGAEDRA, the name of a genus of cryſtals.

The word is derived from the Greek ὀλιγος, *a few*, and ἑδρα, *a plane*, or *ſide*, and expreſſes a cryſtal, which is compoſed of only a few planes.

The bodies of this claſs are cryſtals of the imperfect kind, being compoſed of columns affixed irregularly to ſome ſolid body at one end, and, at the other, terminated by a pyramid; but the column and pyramid being both pentangular, the whole conſiſts only of ten planes, not, as the common kind, of twelve.

OLIGARCHY, formed from ὀλιγος, *few*, and αρχη, *government*, a form of government, wherein the adminiſtration is in the hands of a few perſons.

The ſtates of Venice and Genoa may be ranked among oligarchies.

Oligarchy amounts to much the ſame thing with ariſtocracy; unleſs perhaps the former imports a kind of defect or corruption; as if the ſovereign power were monopolized by a few perſons, in prejudice of the rights of a great number.

OLIGARRHENA, in *Botany*, ſo named by Mr. Brown, from ὀλιγος, *few*, and αρρην, *a male*, becauſe of the ſtamens being but two, though uſually, in the natural order to which the plant belongs, they are five.—Brown Prodr. Nov. Holl. v. 1. 549.—Claſs and order, *Diandria Monogynia*. Nat. Ord. *Epacrideæ*, Brown.

Eſſ. Ch. Calyx in four deep ſegments, with two ſcales at the baſe. Corolla four-cleft, its ſegments not imbricated in the bud, permanent. Stamens within the tube. Germen of two cells. Capſule? of two cells.

1. O. *micrantha*. Gathered by Mr. Brown on the ſouthern coaſt of New Holland. A ſmall, upright, much branched *ſhrub*. *Leaves* ſcattered, imbricated, minute. *Spikes* terminal, erect. *Flowers* ſmall, white, with four ſcales, or nectaries, under the *germen*.

A paradoxical plant, in its artificial characters not much unlike the natural order of *Oleinæ*, but in habit totally different. *Br.*

OLIGOTROPHEROS, among the Greeks, a name given to the finer ſort of bread made of the fineſt flour.—They called it by this name becauſe of the little ſhare of nouriſhment it conveyed; and by way of diſtinction from it, called the brown bread *polytropheros*, or *much nouriſhing*.

OLIKA, in *Geography*, a town of Poland, in Volhynia; 23 miles N.E. of Lucko.

OLIKAN, a ſmall iſland of Ruſſia, in the Penzinſkoi ſea. N. lat. 60° 16′. E. long. 155° 36′.

OLIL, a town of Africa, in Calbari, on the Rio del Rey. N. lat. 4° 15′.

OLIMPIA, a town of European Turkey, in the Morea; 32 miles S.S.E. of Chiarenza.

OLIMPO, a mountain of European Turkey, in Theſſaly; 10 miles N. of Lariſſa.—Alſo, a mountain of Aſiatic Turkey, in Natolia; 50 miles N.W. of Kintaja.

OLINA, in *Ancient Geography*, a town of Spain, in the Tarragonenſis, ſituated in the interior of the country of the people called Callaici Lucenſci. Ptolemy.

OLINDA, in *Geography*. See FERNAMBUCO.

OLIO, or OGLIO, a ſavoury diſh, or food, compoſed of a great variety of ingredients; chiefly found at Spaniſh tables.

The forms of olios are various. To give a notion of the ſtrange aſſemblage, we ſhall here add one from an approved author.

Take rump of beef, neats tongues boiled and dried, and Bologna ſauſages; boil them together, and, after boiling two hours, add mutton, pork, veniſon, and bacon, cut in bits; as alſo turnips, carrots, onions, and cabbage, borage, endive, marigolds, ſorrel, and ſpinach; then ſpices, as ſaffron, cloves, mace, nutmeg, &c. This done, in another pot put a turkey or gooſe, with capons, pheaſants, wigeons, and ducks, partridges, teals, and ſtock-doves, ſnipes, quails, and larks, and boil them in water and ſalt. In a third veſſel, prepare a ſauce of white wine, ſtrong broth, butter, bottoms of artichokes, and cheſnuts, with cauliflowers, bread, marrow, yolks of eggs, mace, and ſaffron: laſtly, diſh the olio, by firſt laying out the beef and veal, then the veniſon, mutton, tongues, and ſauſages, and the roots over all; then the largeſt fowls, then the ſmalleſt, and laſtly pour on the ſauce.

OLIPHANTS, in *Geography*, a town of America, in North Carolina; 20 miles W. of Saliſbury.

OLISI, a town of Hindooſtan, in the Carnatic; 8 miles N.E. of Ongoli.

OLISIPO, in *Ancient Geography*, now *Liſbon*, a town of Hiſpania, in Luſitania, near the mouth of the Tagus. This town was a Roman colony, with the epithet of "Felicitas Auguſta." See LISBON.

OLISTHEMA, from ολισθαινω, *to fall out*, in *Surgery*, a diſlocation, or luxation.

OLITA, in *Geography*, a town of Mexico, in the province of Xaliſco.—Alſo, a town of Lithuania, in the palatinate of Troki; 28 miles S.W. of Troki.—Alſo, a town of Spain, in Navarre, containing, in its preſent reduced ſtate, four churches and two convents; 20 miles S. of Pamplona. N. lat. 43° 30'. W. long. 1° 42'.

OLITORY, a kitchen garden, or a garden of herbs, roots, &c. for food. See GARDEN, SALLET, &c.

OLIVA, GIOVANNI, in *Biography*, a learned antiquary, was born at Rovigo, in the Venetian territory. He embraced the eccleſiaſtical profeſſion, and was ordained prieſt in 1711. His literary reputation cauſed him immediately after to be nominated profeſſor of the belles lettres at Azzolo, which poſt he occupied about eight years. In 1718 he publiſhed at Venice a very learned treatiſe, entitled "De Antiqua in Romanis ſcholis Grammaticorum diſciplina." He was invited to Rome, in 1719, by pope Clement XI., and appeared with diſtinction among the learned men of that capital. On the diſcovery of a four-footed iſis among ſome ruins, he wrote a Latin diſſertation upon it, in which he diſplayed much erudition reſpecting Egyptian mythology. In 1722 the cardinal Rohan appointed Oliva to be his librarian, in which office he continued during the remainder of his life, occupying himſelf indefatigably in enriching the vaſt collection of that prelate, and drawing up an exact account of its contents. The catalogue amounted to twenty-five volumes in folio. He gave an edition, in 1723, of ſome letters of Poggio, which had hitherto remained in manuſcript. He died at Paris in 1757; after his death were printed his works, conſiſting of the two diſſertations already referred to, together with another, pronounced at Azzolo, "On the Neceſſity of adding the Study of Medals to that of Hiſtory." Moreri.

OLIVA, in *Geography*, a ſea-port town of Pomerania, ſituated on a bay in the Baltic, and famous for a treaty of peace which was concluded between the emperor and the kings of Sweden and Poland, in the year 1660; 10 miles W. of Dantzic. N. lat. 54° 26'. E. long. 18° 22'.—Alſo, a town of Spain, in Valencia, near the Mediterranean coaſt, in the vicinity of which ſugar canes are cultivated; 40 miles N. of Alicant.—Alſo, a ſmall iſland in the Mediterranean, near the coaſt of Caramania. N. lat. 36° 25'. E. long. 33° 10'.

OLIVAREZ, *Count de*, in *Biography*, named Gaſpar de Guſman, favourite and miniſter to Don Philip IV. of Spain, ſucceeded Uzeda as prime miniſter, and gained popularity by his wiſe and ſalutary regulations. Notwithſtanding the good he did, he was always an enemy to peace, and it was owing to his ambition that an almoſt general war was excited about the year 1627, which proved very fatal to Spain. His pride and obſtinacy were the cauſe of many calamities to his country. The revolt of the Catalans, whom he wiſhed to deprive of their privileges, was a conſequence of his folly: he had privately employed the marquis de los Velez to extinguiſh this rebellion; but the cruelty of the meaſures uſed for this purpoſe only inflamed it the more. The revolution of Portugal, which was terminated by its ſeparation from the Spaniſh provinces, another diſaſtrous event, was alſo the reſult of his temper. The great ſecret by which Olivarez had governed his maſter, was being the companion, or at leaſt the confidant, of his pleaſures. While he attempted to deceive the world with a ſpecious appearance of religion and piety, he was not only immerſed in vice himſelf, but encouraged and promoted it in the monarch, to the ſcandal of his ſubjects, and the prejudice of his affairs. At length his ſchemes began to be entirely broken and defeated; he fell under the diſpleaſure of the queen, the emperor, the grandees, and the people, at one and the ſame time, and experienced the diſgrace which he had long merited. He was baniſhed to Toro, where, worn out by infirmities, or overcome by deſpair, he ended his days about the year 1645.

OLIVAREZ, in *Geography*, a town of Spain, in Old Caſtile; 18 miles S.E. of Valladolid.

OLIVARIA CORPORA, in *Anatomy*, two ſmall eminences of the medulla oblongata. See BRAIN.

OLIVAS, in *Geography*, a town of Portugal, in the province of Beira; 6 miles S.W. of Viſeu.

OLIVE, PETER JOHN DE, in *Biography*, a celebrated Franciſcan monk in the thirteenth century, was regarded as chief of that branch of the order which diſputed ſo frequently with the popes, in favour of the renunciation of property in obedience to the inſtitution of St. Francis. He acquired, by his writings, a high reputation for ſanctity and ſound learning, and drew after him a number of followers. One of the great objects which he ſeems never to have loſt ſight of in his writings, was the corruption of the church of Rome, which he cenſured with great ſeverity, in a work entitled "Poſtilla, or a Commentary on the Revelation," affirming boldly that the church was repreſented by the woman, upon whoſe forehead was a name written, "Myſtery, Babylon the great, the mother of harlots, and abominations of the earth," whom St. John ſaw ſitting "upon a ſcarlet-coloured beaſt, full of names of blaſphemy, having ſeven heads and ten horns." It muſt be obſerved, that this cenſor

of the church was himſelf a moſt ſuperſtitious fanatic in ſeveral reſpects, having imbibed the greateſt part of thoſe opinions which the ſpiritual Franciſcans pretended to have received from the abbot JOACHIM; ſee his article. He went ſtill farther, and contended that St. Francis, whom he conſidered as wholly and entirely transformed into the perſon of Chriſt, was the ſubject of adoration. He was himſelf accuſed of hereſy, and cenſured by his judges, but ſubmitting to the judgment patiently, he eſcaped the ſevere treatment to which many of his followers were ſubjected. He died in 1297, and it was pretended, that miracles were wrought at his tomb. The zeal with which he defended the cauſe of the gloomy Franciſcans, in his "Treatiſe on Poverty," and his other writings, led them to venerate him as a ſaint. But in the year 1325, pope John XXII. ordered his bones to be taken from the tomb, and publicly burnt, together with his writings; pope Sixtus IV., however, ordered his works to be examined anew, and a ſentence was now pronounced in their favour, or at leaſt as containing no doctrines nor precepts inconſiſtent with the true Catholic faith or good morals. Moreri.

OLIVE, *Spurge*. See SPURGE *Laurel*.

OLIVE, *Wild*. See OLÆAGNUS.

OLIVE, *Barbadoes Wild*. See BONTIA.

OLIVE-*Colour* is a yellow mixed with black.

The term is chiefly uſed in ſpeaking of the tincture of the complexion: the Spaniards and Indians are rarely white, generally olive-complexioned.

OLIVE *Iſland*, in *Geography*, a ſmall iſland in the Mergui Archipelago, hardly a mile in circumference; captain Forreſt found on this iſland ſome trees of the true olive. N. lat. 11° 20'.

OLIVECRANTZ, JOHN PAULIN, in *Biography*, known as a member of the council of Chriſtina, queen of Sweden, was the ſon of a Swediſh archbiſhop, and born in 1633. He was carefully inſtructed by his father in claſſical learning, and made very conſiderable progreſs in his ſtudies. In 1658 he was appointed ſecretary of legation to Frankfort, in order to be preſent at the election of the emperor. He was afterwards ſent ambaſſador to Nimeguen, to aſſiſt in the negociations for peace; and in 1680 was made governor of Revel, and ſupreme judge of Gothland. He was in high favour with Chriſtina, who commanded him to prefix to his title the qualification of excellency, a circumſtance which gave riſe to much jealouſy, and excited againſt him a hoſt of enemies. The queen correſponded with him after her abdication, and endeavoured to perſuade him to follow her to Rome. He died at Stockholm in 1707, and is eſteemed by his countrymen as one of their beſt Latin poets. His principal works are "Oratio in Laudes Reginæ Chriſtinæ Græce habita Upſaliæ;" "Magnus Principatus Finlandiæ Epico Carmine depictus Oratione Græca Holmiæ." Gen. Biog.

OLIVEIRA *de Bairro*, in *Geography*, a town of Portugal, in the province of Beira; 21 miles N. of Coimbra.

OLIVEIRA *de Condé*, a town of Portugal, in the province of Beira; 12 miles S.W. of Viſeu.

OLIVENÇA, a town and fortreſs of Portugal, in Alentejo, on the borders of Spain; to which country it was ceded by the peace of Badajoz, ſigned June the 6th, 1801; 13 miles S. of Elvas. N. lat. 38° 30'. W. long. 6° 50'.

OLIVER, ISAAC, in *Biography*, one of the firſt Engliſhmen who roſe to any tolerable degree of eminence in the art of painting; the firſt rudiments of which he imbibed from N. Hilliard; but was principally indebted for inſtructions to Frederic Zucchero. He was born in 1556. His principal employment was in portraits, and thoſe in miniature, which he wrought with great reſemblance to nature in form and character, and his touch was uncommonly delicate. He ſometimes employed himſelf in making drawings upon a large ſcale, and alſo in painting in oil colours; but to neither of theſe is he indebted for his reputation ſo much as to his miniatures. Many very fine ones of his painting ſtill remain in poſſeſſion of the nobility of this country.

Dr. Meade's collection was very rich in them; one of queen Elizabeth, others of Mary queen of Scots, Henry prince of Wales, Ben Johnſon, and ſir Philip Sidney, at whole length, ſitting under a tree: theſe were all purchaſed by the king's father, Frederic prince of Wales, and now form a part of his majeſty's collection. They are moſt to be admired for their extreme neatneſs and truth; with a taſteful expreſſion of feature rarely found in portraits; but their actions are void of grace, and exhibit the general want of taſte in art at that period. He died in 1617, aged 61.

OLIVER, PETER, the ſon and diſciple of Iſaac Oliver, was born in 1601, and ſucceeded his father in the profeſſion of miniature painting, confeſſedly even more ſucceſsful than him or any of their contemporaries. His pictures, like his father's, are ſpread among the houſes of the nobility and gentry, and are alike juſtly eſteemed. The works which he executed upon a larger ſcale are much more valuable than thoſe of his father, and are alſo more numerous, though not very frequently to be met with. Walpole mentions that there were thirteen works of Peter Oliver in the collection of Charles I. and of James II.; and that ſeven of them are preſerved in queen Caroline's cloſet at Kenſington; and he alſo ſpeaks of a portrait of Mrs. Oliver by her huſband, in poſſeſſion of the ducheſs of Portland, as being of uncommon quality. He died in 1660.

OLIVERI, in *Geography*, a river of Sicily, which runs into the ſea, between Patti and Milazzo.

OLIVES, *Mount of*, or *Mount* OLIVET, in *Biblical Geography*, a mountain of Paleſtine, which is ſituated about a mile diſtant from Jeruſalem, and commands the proſpect of the whole city, from which it is parted by the brook Kidron, or Cedron, and the valley of Jehoſhaphat. This is not a ſingle hill, but rather part of a long ridge, with three, or, according to Pococke, four, heads or ſummits, extending from N. to S.; the middleſt of which is that from which our Saviour aſcended into heaven. On this ſummit is a ſmall round church. Here was formerly a magnificent church, built by the empreſs Helena, in memory of Chriſt's aſcenſion; but there now only remains a Gothic octagonal cupola, about eight yards in diameter. The natives have here two altars; and the Greeks, Copts, and Armenians, one each, in which they ſay maſs; but Chriſtians of every deſcription have free acceſs to the place throughout the whole year, upon paying a certain caphar, or tribute. Every place that is ſhewn upon this mountain has either a church, chapel, or oratory, to feed the devotion of pilgrims, and the indigence of the monks that reſide upon the ſpot. The ſecond ſummit of the mountain, towards the S., is that called the "Mount of Corruption or Offence." The third, towards the N., which is the higheſt ſummit of all, and ſtands about two furlongs from the middleſt, is that which was moſt commonly ſtyled the "Mount of Galilee." Here are alſo ſhewn many places mentioned in the goſpel; ſuch as that where Chriſt mounted the aſs; where he wept over Jeruſalem, &c. Theſe are ſtill viſited by multitudes of Chriſtians of all ſorts; though the Latins have the poſſeſſion of them, and perform the particular ceremonies that

belong

belong to each reſpective place; *e. g.* on Palm Sunday, the monks and prieſts attend their ſuperior from the place where Chriſt, mounted on an aſs, proceeded to Jeruſalem. He is dreſſed in his pontifical habit, mounted alſo on an aſs, and accompanied by crowds of ſpectators, who cut down and ſtrew branches before him, and make the air reſound with their harangues. The mount of Olives was originally called by the Jews the "Mount of Unction," on account of the great quantity of oil that was made from the olives that grew upon it; but when Solomon had once defiled it, by erecting ſundry temples to the gods of the Ammonites, Moabites, &c. in complaiſance to his ſtrange wives, they changed the name of it by a ſmall alteration of the letters, that is, of שחה into משחית, into another, which ſignifies the "Mount of Corruption, Deſtruction, or Offence." The Greeks, however, have retained its ancient appellation of Ὄρος ελαιῶν, or Ὄρος τῶν ἐλαιῶν, mount of olives.

The evangeliſt Luke, ſuppoſed to be the writer of the Acts, as well as of the goſpel that bears his name, has been charged by one advocate of the cauſe of infidelity, with having contradicted himſelf; for in his goſpel he tells us, that Jeſus aſcended into heaven from Bethany; and in the Acts of the Apoſtles he informs us, that he aſcended from mount Olivet. This objection proceeds, as the learned biſhop of Landaff has obſerved in his excellent "Apology for Chriſtianity," either from ignorance of geography, or ill-will to Chriſtianity; and he recommends to the writer to recollect for the future, that Bethany was not only the name of a town, but alſo of a diſtrict of mount Olivet adjoining to the town.

OLIVET, Joseph Thoullier d', in *Biography*, an eſtimable man of letters, was born in 1682 at Salins, in Franche Compté. He was educated by his father, who was afterwards a counſellor in the parliament of Beſançon, and at an early age he entered among the Jeſuits, in which ſociety he had an uncle diſtinguiſhed for his learning. During his continuance among the Jeſuits, he frequently viſited Boileau, and his admiration of the poet cauſed him to imbibe his principles of literature. The taſte which he acquired was rather manly and auſtere, than refined; and it was accompanied with a correſponding bluntneſs of manners and addreſs. The example of his friend led him to make trial of his powers in French verſe; but in the maturity of his judgment he committed all his poetry into the flames. He exerciſed himſelf in compoſitions for the pulpit; and in order to form his taſte for oratory on the beſt models, he became a very aſſiduous ſtudent of the works of Cicero. He was invited to undertake the tuition of the prince of Aſturias in Spain, which he declined, preferring the eaſe and independence of a private ſtation to a brilliant ſervitude. At the age of thirty-three he quitted the ſociety of the Jeſuits, and thenceforward devoted himſelf to the life of a man of letters at Paris, and in 1723 he was elected into the French academy. The firſt work which he committed to the preſs was a tranſlation of Cicero, "De Natura Deorum." After this he publiſhed the Tuſculan queſtions, and the orations againſt Catiline: and, at a ſubſequent period, he collected from the works of Cicero thoſe paſſages which he thought beſt calculated, as well to form the literary taſte of young perſons, as to inſpire them with uſeful moral principles, and publiſhed them in a tranſlation, under the title of "Penſées de Ciceron, pour ſervir a l'Education de la Jeuneſſe." A complete edition of the works of his favourite author was an object that long and deeply engaged his attention, which he at length brought out at Paris, under the patronage of the government, in nine volumes 4to. An edition of this work was publiſhed at Geneva in 1758, which is in the higheſt eſtimation, is very rare, and fetches a very high price. To each volume are attached tables, particularly an uſeful one, containing all the various readings collected from the principal editions of Victorius, Manutius, Lambinus, and Gruterus, together with thoſe propoſed by Olivet in his Commentaries. Of the edition, by this editor, the biographer ſays, "it is the character that it performs more than it promiſes. Beſides a very correct text, it contains a very judicious collection of notes by the beſt commentators, with a learned and well-written preface of his own." In the Geneva edition, the errors that had eſcaped M. Olivet are carefully corrected.

Olivet was a diligent ſtudent of the grammar of his own language, and publiſhed a treatiſe on "French Prolody," in which he attempted to prove that almoſt all French ſyllables have a determinate meaſure, and are as ſuſceptible of quantity as thoſe of Greek and Latin. This was ſucceeded by "Remarques de Grammaire ſur Racine." His attachment to the French academy led him to write the hiſtory of that body in continuation of that of Peliſſon. This work, which comes down to the commencement of the 18th century, is valuable for the accuracy of its reſearches, and the intereſting anecdotes preſerved in it. He publiſhed "Opuſcules ſur la Langue Françoiſe," to which he added the abbè de Choiſi's "Journal of Diſcuſſions," on points of grammar, at the ſittings of the academy. He was a moſt regular attendant on the meetings of the French academy, and on his return from one of them, in October 1768, he was attacked with a fit of apoplexy, which terminated his life at the age of 86.

As a tranſlator, Olivet is faithful and elegant: to his verſion of the treatiſe "De Natura Deorum," he annexed a tract of his own relative to ancient philoſophy, which he entitled "Theologie des Philoſophes," to which theology, according to D'Alembert, his philoſophical knowledge was in a great meaſure limited. The abbè d'Olivet was ever ready to perform good offices for his literary brethren, and through his means many ſcholars obtained eligible and reſpectable ſituations in life. He had familiar acceſs to cardinal Fleury, the prime miniſter, and the biſhop of Mirepoix, the diſtributor of eccleſiaſtical beneſices, who could not but admire the intereſt which he took in obtaining favours for others, while he aſked nothing for himſelf. He preſerved to the end of his life the intimate friendſhip of ſeveral perſons of eminence, and though ſparing in his approbation of modern productions, he appears to have been free from envy and jealouſy. In his mode of living he was moderate and economical; and he ſacrificed the greateſt part of his patrimony to the advantageous ſettling of his nephews. Gen. Biog.

Olivet, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the diſtrict of Orleans, ſituated on the S. ſide of the Loire; 3 miles S. of Orleans. The place contains 3250, and the canton 7102 inhabitants, on a territory of 185 kiliometres, in 7 communes.

OLIVETAN, Robert, in *Biography*, the firſt perſon who publiſhed a verſion of the ſcriptures in the French language, from the original Hebrew and Greek Septuagint, for the uſe of the inhabitants of the Valais. Of his hiſtory nothing is known, except that he was a relation of John Calvin, and he is ſaid to have been poiſoned at Rome in the year 1536. His tranſlation was printed at Neufchatel in 1535, and was the foundation of the Geneva verſion in common uſe, after it had gone through various reviſions by Calvin, Beza, and others. The character of Olivetan's impreſſion is Gothic: he is ſaid to have committed many miſtakes,

miſtakes, but it was no ſmall thing gained to have the ſcriptures, in any way, given in the vernacular language of the country. Calvin's firſt reviſed edition of this tranſlation came out at Geneva in 1550, copies of which, as well as of Olivetan's in the Gothic character, are now exceedingly ſcarce.

OLIVIER, SERAPHIM, a learned French eccleſiaſtic, who was promoted to the purple in the early part of the ſeventeenth century, was born at Lyons in the year 1538. He ſtudied the civil and canon law at Bologna, after which he went to Rome, and obtained the patronage of pope Pius IV., who made him auditor and dean of the *Rota*, which poſts he retained during forty years. He was employed as nuncio by popes Gregory XIII., Sixtus V., and Clement VIII., of whom the latter, in 1604, beſtowed upon him the title of patriarch of Alexandria, and raiſed him to the ſacred college, at the recommendation of king Henry IV. He was likewiſe nominated to the biſhopric of Rennes in Britanny. He died in 1609, at the age of ſeventy-one. He prepared for the preſs "Deciſiones Rotæ Romanæ," which were printed at Rome in 1614, in two volumes folio, and were reprinted at Frankfort in the following year. Moreri.

OLIVIER, CLAUDE MATTHIEU, advocate of the parliament of Aix, was born at Marſeilles in 1701. He was brought up to, and ſucceſsfully practiſed at the bar. He poſſeſſed a quick and lively genius; and at any time, a few hours retirement from ſociety was ſufficient to enable him to ſpeak and write, even on important cauſes. He was a man of great talents, but took little pains to improve them; he was given to exceſs in almoſt every thing; he would employ a fortnight in ſtudying the Code and the Digeſt, or in ſtoring his mind with the beauties of Demoſthenes, Homer, Cicero, or Boſſuet, and then abandon himſelf to a life of frivolity and diſſipation. He died in 1736, at the age of 35. He had a chief hand in the eſtabliſhment of the academy of Marſeilles, and was of courſe one of its original members. He publiſhed (1) "L'Hiſtoire de Philippe Roi de Macedoine, et Père d'Alexandre le Grand," in two vols. 12mo. No writer, it is ſaid, has ſo ably handled the hiſtory of the age of Philip, the intereſts of the different nations of Greece, and their manners and cuſtoms, but the conduct of the work is extremely defective; the digreſſions are frequent and tedious, and the ſtyle is not ſuitable to a hiſtory. A diſeaſe of the brain, with which he was attacked, and under which he laboured a long time, prevented him from putting his laſt hand to this work. 2. "Mèmoire ſur les Secours donnès aux Romains par les Marſeillois pendant le ſeconde Guerre Punique." 3. "Mèmoire ſur les Secours donnès aux Romains par les Marſeillois durant la Guerre contre les Gaulois."

OLIVIN, *Volcanic Chryſolite*, *Peridot granuliforme*, Haüy, in *Mineralogy*, a ſpecies of *Chryſolite* (ſee CHRYSOLITE), the colour of which is between aſparagus and olive-green, and which, by expoſure to the weather, becomes yellowiſh-brown. It occurs imbedded in baſalt, ſometimes in rounded pieces, and rarely in rectangular priſms. Its luſtre varies internally between glimmering and ſhining, and is vitreous, paſſing into reſinous. Its fracture conchoidal, paſſing into ſplintery and uneven, and its fragments indeterminately ſharp-edged. In large pieces it exhibits granular diſtinct concretions. It varies from ſemi-tranſparent to tranſlucent; it is hard, but leſs ſo than quartz; brittle and eaſily frangible. Sp. gr. 3.22 to 3.26: nearly infuſible before the blowpipe, without addition, and loſes its colour by digeſtion in nitric acid. The analyſis of it by Klaproth is as follows:

	48.	to	52.	Silex
	37.	—	38.5	Magneſia
	0.25	—	0.20	Lime
	12.5	—	12.	Oxyd of iron
	97.75			
Loſs	2.25			
	100.			

It is eaſy of decompoſition, and to this circumſtance many baſalts owe their porous texture. Olivin is found very abundantly in Bohemia and other parts of Germany, and alſo in France, Britain, Norway, and Sweden. Aikin's Dict.

OLIZAROWSTOW, in *Geography*, a town of Poland, in the palatinate of Brzeſc; 14 miles E. of Brzeſc.

OLKILUOTO, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 61° 15′. E. long. 21° 15′.

OLKINIKI, a town of Lithuania, in the palatinate of Troki; 22 miles S. of Troki.

OLKOWITZ, or ALEXOWICE, a town of Moravia, in the circle of Znaym; 9 miles N.E. of Znaym.

OLKUSZ, or ILKUSK, a town of Poland, in the palatinate of Cracow; formerly celebrated for its mines; 16 miles N.W. of Cracow.

OLLA, a river of Germany, which runs into the Weſer; 17 miles below Bremen.

OLLA, in *Mythology*, was the pot in which the prieſts boiled the portion of the victims that was allotted to them.

OLLBRUCKEN, in *Geography*, a town of France, in the department of the Rhine and Moſelle, late the capital of a lordſhip, in the electorate of Cologne; 18 miles N.W. of Coblentz.

OLLERIA, a town of Spain, in the province of Valencia; 5 miles S. of St. Felipe.

OLLEROS POINT, a cape and harbour on the coaſt of Peru; S. lat. 14° 36′.

OLLET, in *Rural Economy*, a term applied to fuel of any kind.

OLLIERGUES, in *Geography*, a town of France, in the department of the Puy-de-Dôme, and chief place of a canton, in the diſtrict of Ambert; 9 miles N.N.W. of Ambert. The place contains 1760, and the canton 7192 inhabitants, on a territory of 147½ kiliometres, in 5 communes.

OLLIOULLES, a town of France, in the department of the Var, and chief place of a canton, in the diſtrict of Toulon; 4 miles W. of Toulon. The place contains 2591, and the canton 14,363 inhabitants, on a territory of 195 kiliometres, in 6 communes.

OLLYA, a town of Bengal; 30 miles S.W. of Rogonatpour.

OLMAN, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 61° 38′. E. long. 17° 11′.

OLMEDILLA, a town, or rather village, of Spain, in New Caſtile, ſituated on the road from Madrid to Valencia, and half way on the royal route leading to thoſe two capitals.

OLMEDO, a ſmall town of Spain, ſeated on an eminence in front of an extenſive plain: it was formerly ſurrounded by walls, of which ſome remains are ſtill viſible; it has ſeven parochial ſtructures, and as many religious houſes. The principal altar of St. Mary's church is adorned with good paintings. The population of this place was more conſiderable, but is now reduced to the number of 2000 inhabitants, who carry on no other traffic than

than that which is derived from their brick-kilns. In its vicinity are ſome vineyards and kitchen-gardens. It is under the adminiſtration of a corregidor; 16 miles S. of Cuença.

OLMESSA, a town of the iſland of Corſica; 5 miles N.E. of Corte.

OLMESTA, a town of Sweden, in Eaſt Gothland; 30 miles S.W. of Linkioping.

OLMETO, a town of the iſland of Sardinia; 7 miles N. of Alghieri.—Alſo, a town of the iſland of Corſica; 7 miles W. of Tallano.

OLMETTA, a town of Corſica; two miles S.W. of Oletta.

OLMOS, Fr. Andres de, in *Biography*, was born near Oria, in the diſtrict of Burgos, in the latter part of the fifteenth century, and was brought up in the houſe of a married ſiſter at Olmos, near Valladolid, from which place he took his name. At the age of twenty he took the Franciſcan habit in the convent at Valladolid. He diſtinguiſhed himſelf by his application to theological ſtudies, and was ſent by Charles V. as one of the inquiſitorial commiſſioners againſt the witches of Biſcay. He acquitted himſelf ſo much to the ſatisfaction of his companion Zumarraga, that when the latter was appointed biſhop of Mexico, in 1528, he took Olmos with him to the new world. Here his zeal was wiſely directed, and he began a ſeries of labours which entitle him to the reſpect of poſterity. He found it neceſſary to learn four languages, *viz.* the Mexican; the Totonaca; the Tepehua; and the Guaxteca. Of the two firſt he wrote grammars and vocabularies, which have been of eſſential ſervice to other miſſionaries. He was author of very many religious tracts, in the different languages of the tribes among whom he paſſed the greater part of his life, enduring with patience and fortitude every kind of privation and difficulty. He lived, however, to a great age, and died in October 1571. He is ranked among the poets of Spain, having tranſlated into Caſtilian verſe a Latin work upon Hereſy, by Alonzo de Caſtro. Gen. Biog.

OLMUS, in the *Inſtrumental Muſic of the Ancients*, the name of one of the joints of the ancient flutes, and probably the upper joint or embouchure. See Bombyx.

OLMUTZ, in *Geography*, a city and capital of the marquiſate of Moravia, and of a circle of the ſame name, ſeated on the river Morawa, the firſt royal borough and ſee of a biſhop, ſurrounded by the river. It is a fortified, well-built, and populous town; divided into the Old and New Town, and containing twenty-ſix churches, five chapels, ſeven cloiſters of monks, and two of nuns, ſeveral hoſpitals, a correction and an orphan-houſe, a college and ſeminary, an univerſity, founded in 1567, a riding academy, and a learned ſociety. The caſtle is ſtrong, and has often ſerved as a ſtate priſon; 89 miles N.N.E. of Vienna. N. lat. 49° 33′. E. long. 17° 11′.

OLNEY, or Oulney, a market town and pariſh in the firſt diviſion of the three hundreds of Newport, and county of Buckingham, England, is ſituated on the north bank of the river Ouſe, near the borders of Northamptonſhire, and at the diſtance of fifty-ſix miles from the metropolis. The houſes in the town, except thoſe of late erection, are moſtly covered with thatch, and chiefly ranged in one long ſtreet. In 1786, a fire happened here, which deſtroyed forty-three large tenements, and occaſioned other conſiderable damage. The church is a large ancient ſtructure, in the pointed ſtyle, adorned with a handſome tower and ſpire, the latter riſing to the height of 185 feet. In the cemetery formerly ſtood a chapel, dedicated to the Virgin Mary, in which was a chantry, founded by lord Baſſet. Lace-making conſtitutes the chief employment of the inhabitants of Olney. The market is held on Monday every week, and there are three fairs annually. According to the parliamentary returns of 1811, this town and pariſh contain 484 houſes, and a population of 2268 perſons. Previous to the year 1767, the pariſh of Olney was one entire common, but at that period it was incloſed under the authority of an act of parliament. The manor anciently belonged to the earls of Cheſter, from whom it paſſed to the two families of Albini and Baſſet. It afterwards became the property of Thomas Moubray, duke of Norfolk, after whoſe baniſhment the king granted it to Edward, duke of York, who was ſlain at the battle of Agincourt. Upon this event it reverted to the crown, and continued part of the royal demeſnes till the year 1638. Its preſent proprietor is the earl of Dartmouth.

Weſton-Underwood, a ſmall village ſituated about a mile ſouth from Olney, was long the reſidence of the celebrated poet Cowper, who died here on the 25th of October 1800. Many deſcriptions in his poem of the Taſk were drawn from the ſcenery adjoining to this town. At Lavendon, two miles to the north, formerly ſtood an abbey for Premonſtratenſian monks, founded by John de Bidun, a baron, in the reign of Henry II. This place appears to have been anciently of much more importance than at preſent, as it had a weekly market and an annual fair; and was protected by a caſtle, ſome veſtiges of which can ſtill be traced. Ravenſton, to the weſt of Olney, is noted as the birth-place of the great lord chancellor Nottingham, who was ſtyled by his contemporaries the Engliſh Cicero, and who is characteriſed by the late ſir William Blackſtone as a lawyer of firſt rate abilities and ſterling integrity. He died in 1682, after having been advanced to the dignity of an earl, and lies buried in the church of this village, where is a magnificent monument erected to his memory by his ſon. His effigy is finely executed in white marble, in his chancellor's robes, and reclines under a canopy ſupported by four black marble pillars of the Corinthian order. Magna Britannia, by the Rev. Dan. Lyſons, A.M. F.R.S. and Samuel Lyſons, eſq. F.R.S. 4to.

OLOBOK, a town of the duchy of Warſaw; 12 miles S. of Kaliſch.

OLOC, in *Natural Hiſtory*, a name given by the people of the Philippine iſlands to their quail. It is like our's in all reſpects, but much ſmaller.

OLOCENTROS, a name given by the old Greeks to a ſmall animal of the ſpider kind, whoſe bite was accounted mortal. It is the ſame with the *ſolipuga*, ſo called from its ſtinging, or biting moſt violently, in places, or ſeaſons, where the ſun had the moſt power, as Africa, &c. The name *ſolifuga* was a corrupt way of writing that word, and this ſeems alſo a falſe way of writing the word *heliocentros*, which ſignifies the ſame as *ſolipuga*.

OLOMPAN, in *Geography*, a town of Mexico; 40 miles E.N.E. of Mexico.

OLONA, a river of Italy, which runs into the Po; 12 miles W. of Piacenza.—Alſo, the name of one of the twelve departments of Italy, formerly a part of the duchy of Milan, which is divided into four diſtricts, and contains above 193,189 inhabitants, who elect fifteen deputies. The capital is Milan.

OLONEI, an iſland near the S. coaſt of Nova Zembla, in the ſtraits of Vaigatſkoi. N. lat. 70° 30′. E. long. 58° 29′.

OLONETZ, a town of Ruſſia, built by Peter I., in which is an iron forge, and in its vicinity are mines of copper and iron, and a mineral ſpring; 104 miles N.E. of Peterſburg. N. lat. 61° 10′. E. long. 32° 38′.

OLO-

OLONETZKOI, a government of Ruſſia, bounded on the N. by the government of Archangel, on the E. by the ſame and the White ſea, on the S. by that of Novgorod and Vologda, and on the W. by that of Viborg and Finland; about 340 miles from N. to S. and in its greater breadth from E. to W. 240 miles; but along the White ſea its mean breadth is about 100. Olonetz, from which it derives its name, is the capital. N. lat. 61° 40′ to 66° 40′. E. long. 28° to 41°.

OLONNE, Sables d'. See Sables *d'Olonne*.

OLONSKA, a town of Ruſſia, in the government of Irkutſk; 48 miles S.E. of Balaganſkoi.

OLONZAC, a town of France, in the department of the Herault, and chief place of a canton, in the diſtrict of St. Pons; 15 miles S. of St. Pons. The place contains 850, and the canton 6716 inhabitants, on a territory of 257½ kiliometres, in 13 communes.

OLOPHRYME, in the *Muſic of the Ancients*, according to Athenæus, was the title of funeral ſongs with the Greeks.

OLOSOTAI, in *Geography*, a town of Aſia, in the country of Hami; 20 miles N.N.W. of Tche-tcheou-Hotun.

OLOST, a town of Spain, in Catalonia; 9 miles W.N.W. of Vique.

OLOSTELESEK, a town of Tranſilvania; 22 miles N.N.W. of Cronſtadt.

OLOT, a town of Spain, in Catalonia; 17 miles N.W. of Gerona.

OLOU-HOCHO, a town of Chineſe Tartary; 38 miles S.S.W. of Soubarkan.

OLOUS, a town of Aſiatic Turkey, in Natolia; 12 miles E. of Amaſreh.

OLPE, a town of Germany, in Weſtphalia; 37 miles E. of Cologne. N. lat. 50° 59′. E. long. 7° 59′.

OLPHEN, a town of Germany, in the biſhopric of Munſter; 17 miles S.S.W. of Munſter. N. lat. 51° 42′. E. long. 7° 28′.

OLRICK, a town of Scotland, in the county of Caithneſs; 6 miles E.S.E. of Thurſo.

OLSCHANKA, a town of Ruſſia, in the government of Ekaterinoſlav; 40 miles S.W. of Novo-Mirgorod.

OLSZTYN, a town of Poland, in the palatinate of Cracow; 40 miles N.W. of Cracow.

OLTEN, a ſmall town of Switzerland, in the canton of Soleure, whither the meeting of the Helvetic Society is now transferred. This ſociety conſiſts of the moſt learned men of the country, both of the Catholic and Reformed religion, who firſt contributed to extend the ſpirit of toleration, and to leſſen that antipathy which ſubſiſted between the members of the two perſuaſions. It firſt met at Schintznach, agreeably ſituated on the banks of the Aar, and noted for its tepid and mineral waters. The town of Olten was purchaſed by the canton of Soleure in 1532; 17 miles E.N.E. of Soleure.

OLTENPACH, a town of the duchy of Stiria; 16 miles S.E. of Voirſberg.

OLTIFI, a town of Aſiatic Turkey, in the government of Kars; 30 miles N. of Kars.

OLTRI, a town of Italy, in Friuli; 38 miles N.W. of Friuli.

OLTSCHIN, a town of Auſtrian Poland; 52 miles N.N.W. of Cracow.

OLU Jachseb, a town of Arabia, in the province of Hadramaut; 136 miles S.W. of Amanzirifdin.

OLUTOR, a river of Ruſſia, which runs into the North Pacific ocean. N. lat. 61° 10′. E. long. 167° 54′.

OLUTOROVSKOI, a town of Ruſſia, on the fore-mentioned river, on the coaſt of the Pacific ocean; 164 miles E. of Oklanſk. N. lat. 61° 30′ E. long. 167° 54′. —Alſo, a cape of Ruſſia, in the North Pacific ocean; 100 miles S. of the town of Olutorovſkoi. N. lat. 59° 50′. E. long. 168° 54′.

OLYBRIUS, in *Biography*, a ſhort-lived emperor of the Weſt, had been inveſted with the conſular dignity by Leo, emperor of the Eaſt. When the powerful count Ricimer had reſolved on the depoſition of the emperor Anthemius, he propoſed to raiſe Olybrius to the high dignity, who was alſo ſupported by Genſeric, king of the Vandals. Ricimer laid ſiege to Rome, put to death Anthemius, though his father-in-law, and ordered Olybrius to be proclaimed emperor, A.D. 472. This elevated ſtation he enjoyed a very ſhort time. Ricimer, who had cauſed the death of three emperors, died, and Olybrius ſoon followed him, after a reign of only a few months. Gibbon, in deſcribing the ſiege and aſſault of Rome juſt referred to, ſays, "forty days after this calamitous event, the ſubject, not of glory, but of guilt, Italy was delivered, by a painful diſeaſe, from the tyrant Ricimer, who bequeathed the command of his army to his nephew Gundobald, one of the princes of the Burgundians. In the ſame year, all the principal actors in this great revolution were removed from the ſtage, and the whole reign of Olybrius, whoſe death does not betray any ſymptoms of violence, is included within the term of ſeven months. He left one daughter, the offspring of his marriage with Placidia, and the family of the Great Theodoſius, tranſplanted from Spain to Conſtantinople, was propagated in the female line as far as the eighth generation." Gibbon's Hiſt. vol. vi.

OLYKA, in *Geography*, a town of Poland, in Volhynia; 22 miles N.E. of Lucko.

OLYMPIA, in *Ancient Geography*, a celebrated city of Greece, in Triphylia, ſituated on the river Alpheus, N. of Hypana. It is not certain whether this city had in former times borne the name of "Piſa," or whether they were diſtinct cities. Of all the cities of Greece this was the moſt famous on account of the games which were inſtituted in it, and which drew thither a prodigious concourſe of people. (See Olympics.) At Olympia there was a grove of olives, conſecrated to Jupiter, and which was called "Altis." The temple of the Olympian Jupiter ſurpaſſed all others in beauty, and the ſtatue of this deity which graced this temple was the moſt magnificent of all the works of Phidias, the principal ſculptor of Greece. Its height was ſixty feet: it was formed of gold and ivory, and held in ſuch eſtimation, that it was thought a misfortune for any one to die without having ſeen this ſtatue. The deity was repreſented in a ſitting poſture, with a crown of olive on his head, holding in one hand victory, and in the other a ſceptre, ſurmounted with an eagle. The ſandals of the god, and alſo his robe, are of gold. His throne is diverſified with gold and precious ſtones, with ebony and ivory, and painted with the repreſentations of divers kinds of animals. About it are alſo many figures in ſculpture; *e.g.* four victories in the attitude of dancers, round the upper part of each leg of the throne, and two more at each of the feet. On thoſe legs alſo which ſupport the fore part of the throne, are carved ſphinxes, devouring the Theban children, and under the ſphinxes, Apollo and Diana ſlaying with their arrows the children of Niobe. The baſis or pedeſtal, which ſuſtains the whole work, is enriched with many other ornaments and figures in gold, all of which have ſome relation to Jupiter; ſuch as the Sun mounting his chariot, attended by Jupiter and Juno, and one of the Graces,

Graces, next to whom ſtands Mercury, and next to Mercury Veſta; after Veſta is ſeen Cupid receiving Venus ariſing out of the ſea, and the goddeſs Perſuaſion placing a crown on the head of Venus. Here are alſo the figures of Apollo and Diana, of Minerva and Hercules, and on the loweſt part of the baſis, Neptune and Amphitrite, and the Moon riding on a horſe. Jupiter, as the Eleans ſay, was ſo pleaſed with Phidias, the ſtatuary, for this performance, that, in compliance with his wiſhes, he teſtified his approbation by cauſing the pavement to be ſtruck with lightning, upon which place a brazen urn was fixed as a permanent memorial of the miracle. Phidias is ſaid to have been aſſiſted in the compoſition, the colours, and particularly the drapery of this ſtatue, by Panænus, a painter, his brother and fellow-workman, many of whoſe admirable paintings were ſeen in various parts of the temple. Tradition reports, that Phidias, being aſked by Panænus, by what pattern or idea he intended to frame his image of Jupiter, anſwered, by that given in the following verſes of Homer, lib. i.

> "This ſaid, his kingly brow the Sire inclin'd,
> The large black curls fell, awful, from behind,
> Thick ſhadowing the ſtern forehead of the god;
> Olympus trembled at th' almighty nod."

The temple was of the Doric order, and the place in which it was conſtructed formed a fine periſtyle, being every where encompaſſed by columns; its elevation was 68 feet, its length 230, and its breadth 95. Its architect was Libon, a native of this country, the roof was of fine pentelic marble, cut in the form of tiles. From the middle of the roof hung a gilded victory, and under this ſtatue a golden ſhield, on which was repreſented Meduſa's head. On the outſide above the columns a rope went round the temple, to which were faſtened twenty-one gilt bucklers, conſecrated to Jupiter by Mummius, after the taking of Corinth. Within and about the temple were innumerable ornaments, conſiſting of ſtatues, paintings, and columns charged with trophies. Among the ſtatues were ſeveral of Parian marble, of which ſome had been erected in honour of the emperor Adrian by the cities which compoſed the ſtate of Achaia, and others to Trajan by the whole Greek nation. The city of Olympia was indebted to Trajan for ſeveral of its embelliſhments, particularly the baths, which bore his name, an amphitheatre, a horſe-courſe, two ſtadia in length, and a ſenate-houſe for the Roman magiſtrates, ceiled with bronze. Moſt of the Athletæ had their ſtatues at Olympia, ſeveral of which were executed by Phidias. For other particulars we refer to Pauſanias, lib. v.

OLYMPIAD, Ολυμπιας, in *Chronology*, a ſpace or period of four years; by which the Greeks reckoned their time.

Hiſtorians have ſaid that the Olympiad was inſtituted by Iphitus; but it is certain, that the tetracteris, or period of four years, was almoſt as old as the religions of Greece, being uſed in ſeveral of their ſacra, or religious feſtivals. From Scaliger (Animadv. ad Euſ. Chron. N° 1241.) we learn, that the Greeks, inquiring of the Delphic oracle concerning their ſolemn feaſts and ſacrifices, received for anſwer, that they would do well to ſacrifice καλα τα πελεια, και καλα τρια, according to the cuſtom of their fathers, and according to three things; which laſt words they interpreted to ſignify days, months, and years. They accordingly ſat themſelves to regulate their years by the ſun, and their months and days by the appearances of the moon. Thus they hoped to obſerve their feſtivals, and offer their ſacrifices upon the ſame days and the ſame months in the year; and thus to pleaſe the gods, and to fulfil the intention of the oracle. After trying many forms and combinations of years for this purpoſe, they made their year to conſiſt of 360 days, with two additional days, and their months of 30 days each, from one of which, however, in the courſe of four years, they took a day; by this means their tetracteris amounted to 1447 days. Sometimes a whole month was intercalated, and then the tetracteris conſiſted of 1477 days. In this way they flattered themſelves that the oracle was fulfilled; for they ſacrificed according to the year and the month, becauſe the month was full, as conſiſting of 30 days; and the years thus made up of complete months, by means of theſe intercalations, returned to their beginnings, nearly in the propoſed order. Hence it was, that the great feſtivals of the Greeks were ſolemnized every fifth year, after an interval of four complete years; as, *e. g.* the panathenæa at Athens, and the Olympic games in Elis, which were celebrated every fifth year upon the full of the moon. By Scaliger's tables it appears, that the Olympic new moon fell ſometimes in the middle, or latter end of July, and ſometimes in the beginning of Auguſt, for that feſtival never preceded the ſummer ſolſtice; which the ancients placed always upon the 9th of July, ſo that the Olympic moon was the firſt new moon after the ſummer ſolſtice. This gave birth to the intercalary month, and occaſioned the variation in the tetracteris, which conſiſted ſometimes of 48 months, ſometimes of 49. The utility of the Olympiad as an eſtabliſhed era in the Greek chronology and hiſtory is well known, and, indeed, Scaliger triumphs with no ſmall degree of exultation in the imagined ſucceſs of his reſearches with regard to this period. "Hail," ſays he, "venerable Olympiad! thou guardian of dates and eras! Aſſertrix of hiſtorical truth, and curb of the fanatical licentiouſneſs of chronologiſts! &c. &c." Nevertheleſs, chronologers are far from being agreed about the preciſe time at which the Olympiads began; ſome dating them from the victory of Coræbus the Elean, and others throwing their original 13, and even 28 Olympiads farther backward. This was done by artificial chronologers, who, in order to accommodate the Olympiads to their ſyſtems and computations, have added to their antiquity 112 years, as ſir Iſaac Newton obſerves, in his "Chronology." Chronologers, however, in all their computations, agree to reckon downward from that Olympiad in which Coræbus the Elean was conqueror, the firſt year of which was the 776th B. C., meaning, according to Scaliger, July the 23d. See Epocha.

Rome was built, according to Varro, in the fourth year of the ſixth Olympiad.

The Peloponneſian war began May the 7th in the ſecond year of the 87th Olympiad. Alexander the Great died April the 21ſt, in the ſecond year of the 114th; and Jeſus Chriſt was born in the fourth year of the 193d Olympiad, four years before the common era.

The Olympiads were alſo called *anni Iphiti*, from *Iphitus*, who inſtituted, or at leaſt renewed, the ſolemnity of the Olympic games.

We do not find any computation by Olympiads after the 364th, which ended with the year of Chriſt 440. Except that in a charter of our king Ethelbert, the years of his reign are ſaid to be reckoned by Olympiads.

OLYMPIAS, in *Biography*, a celebrated woman, was daughter of the king of Epirus, who married Philip, king of Macedonia, by whom ſhe had Alexander the Great. Her haughtineſs, and more probably her ſuſpected infidelity, obliged Philip to repudiate her, and marry Cleopatra, the niece of king Attalus. Olympias was ſenſible of this injury, and Alexander ſhewed his diſapprobation of his father's

meaſures, by retiring from the court to his mother. The murder of Philip, which ſome have attributed to the intrigues of Olympias, was productive of the greateſt extravagancies. The queen paid the greateſt honour to her huſband's murderer. She gathered his mangled limbs, placed a crown of gold on his head, and laid his aſhes near thoſe of Philip. The adminiſtration of Alexander, who ſucceeded his father, was in ſome inſtances offenſive to Olympias; but when the ambition of her ſon was concerned, ſhe did not ſcruple to declare publicly that Alexander was not the ſon of Philip, but that he was the offspring of an enormous ſerpent, who had ſupernaturally introduced himſelf into her bed. When Alexander was dead, Olympias ſeized the government of Macedonia; and, to eſtabliſh her uſurpation, ſhe cruelly put to death Aridæus, with his wife Eurydice, as alſo Nicanor, the brother of Caſſander, with a hundred leading men of Macedon, who were inimical to her intereſt. Such barbarities did not long remain unpuniſhed: Caſſander beſieged her in Pydna, where ſhe had retired with the remains of her family, and ſhe was obliged to ſurrender, after an obſtinate ſiege. The conqueror ordered her to be tried, and to be put to death. A body of 200 ſoldiers were ordered to put the bloody commands into execution; but the ſplendour and majeſty of the queen diſarmed their courage, and ſhe was at laſt maſſacred by thoſe who had been injured in themſelves, and in their families, by her tyranny. This happened about three hundred and ſixteen years before the Chriſtian era. Univer. Hiſt.

OLYMPICS, or OLYMPIC *Games*, were ſolemn games, which laſted five days, famous among the ancient Greeks; inſtituted, according to ſome, by Hercules, in honour of Jupiter, and re-eſtabliſhed by Iphitus; and held at the beginning of every fifth year, that is, every 50th month, on the banks of the Alpheus, near Olympia, a city of Elis; to exerciſe their youth in five kinds of combats.

Theſe games became ſo conſiderable, that the Greeks made them their epocha; diſtinguiſhing their years by the returns of the Olympics.

Theſe games have been held in ſuch reputation, and they are ſo nearly connected with the hiſtory of the Greeks, that their vanity has induced them to aſcribe their origin or revival to the moſt venerable perſonages of antiquity, ſuch as the Idæan Hercules, Clymenus, Endymion, Pelops, and Hercules, the ſon of Alcmena; and in order to ſupport theſe different pretenſions, reaſons have been ſought for, and arguments produced from the religious rites and ceremonies, the laws and cuſtoms of this ſolemnity. Thus, Pauſanias ſays, that theſe games were ordered to be celebrated every five years, becauſe the brothers, called the Idæi Dactyli, of whom, the Idean Hercules was the elder, were five in number; to whom, in particular, as alſo to his four brothers, an altar was conſecrated at Olympia by Clymenus, who was deſcended from this Hercules, and is ſaid to have celebrated theſe games fifty years after the deluge of Deucalion. The claims of Endymion are founded on the name of his father Aethlius, who is ſaid to have given the appellation of Athletæ to thoſe who contended for the prize denominated Athlon, at theſe games. As for Pelops, this hero was held in ſuch high veneration at Olympia, that the Eleans in their ſacrifices gave him the preferment, even to Jupiter himſelf, for which they alleged the practice of Hercules, the ſon of Alcmena; to whoſe labours, as Pindar informs us, they were indebted for their olive-crown. The Eleans, not contented with a founder, who was mortal by his mother's ſide, have ſought a ſtill more noble and ancient origin, and have named for the authors of theſe games Jupiter and Saturn; who, as they pretend, in the very place where theſe games were afterwards celebrated, wreſtled with each other for the empire of the world. Others affirm, that they were inſtituted by Jupiter, in commemoration of his victory over the Titans; and that Apollo in particular ſignalized himſelf by gaining two victories, one over Mercury in the foot race, and another over Mars in the combat of the Cæſtus. The name of other heroes might be mentioned, who are ſaid to have celebrated theſe games; the laſt of whom was Oxylus, who came into the Peloponneſus with the Heraclidæ. After him followed ſo long an intermiſſion of the ſolemnity, that the memory of it was almoſt loſt.

As to the occaſions of celebrating the Olympic games, ſir Iſaac Newton is of opinion, that they were originally celebrated in triumph for victories; firſt by Hercules Idæus, upon the conqueſt of Saturn and the Titans; and then by Clymenus, upon his coming to reign in the Terra Curetum; then by Endymion, upon his conquering Clymenus; and afterwards by Pelops, upon his conquering Ætolus; and by Hercules, upon his killing Augeas; and by Atreus, upon his repelling the Heraclidæ; and by Oxylus, upon the return of the Heraclidæ into Peloponneſus. Theſe opinions may be very well ſupported by the teſtimonies of ancient authors. That they were celebrated on occaſion of funerals, is an opinion which is ſanctioned by a cuſtom, which, as we learn from Homer, Pindar, and all the Greek writers, prevailed very much in thoſe heroic ages. The expence of theſe games was ſometimes defrayed by the relatives and friends of the deceaſed, and ſometimes by the public, who enacted an anniverſary ſolemnization of games in honour of the deceaſed. To one or other of theſe cuſtoms was probably owing the original of the Olympic games, as well as of thoſe celebrated at the iſthmus of Corinth, at Delphi, Nemea, and indeed in every conſiderable town throughout all Greece. It is not eaſy to account for the preference given to thoſe celebrated at Olympia; but in this preference all the people of Greece acquieſced, and they agreed to beſtow the firſt honours on the Olympic conquerors. It cannot, however, be pretended, that theſe games were in any very high eſtimation before the time of their inſtitution by Iphitus; who reigned as king of Elis, 884 years B. C. and 108 years before what is vulgarly called the *firſt* Olympiad. Iphitus may, therefore, very juſtly be regarded as the founder of the Olympic games. The occaſion of their re-eſtabliſhment is ſtated as follows; Greece at that time being torn in pieces by civil wars, and waſted by a peſtilence, Iphitus, one of the deſcendants of Hercules, grandſon of Oxylus, and king of Elis, had recourſe to the oracle at Delphi for a remedy to the evils which afflicted the country; and was told by the Pythoneſs, that the ſafety of Greece depended upon the re-eſtabliſhment of the Olympic games; the non-obſervance of which ſolemnity had, as ſhe told them, drawn down the indignation of the god to whom it was dedicated, and of Hercules, the hero by whom it was inſtituted. She ordered him, in conjunction with the people of Elis, to reſtore the celebration of that feſtival, and to proclaim a truce or ceſſation of arms to all thoſe cities which were deſirous of partaking in the games. The other people of the Peloponneſus were ordered by the ſame Delphic deity to join with the Eleans, and to allow them to hold their feſtival, and for that purpoſe to proclaim a ceſſation of arms. The ſecurity and peace which the Eleans thus enjoyed, contributed to render their country rich and flouriſhing; while the other cities of Greece were deſtroying one another with mutual and inteſtine wars; and in this ſtate of tranquillity they were diſtinguiſhed by great ſimplicity and innocence of manners.

The office of "Hellanodick," or preſident at theſe games, was at firſt exerciſed by Iphitus alone, and for 200 years continued to be exerciſed by a ſingle perſon, who was always of the family of Oxylus; but in the 50th Olympiad, the ſuperintendency of the games was committed to two, choſen by lot out of the whole body of the Eleans; and in the 75th, the number was increaſed to nine. Two Olympiads afterwards, a tenth was added; and in the 103d Olympiad, the college of Hellanodicks conſiſted of twelve, correſponding to the tribes of the Eleans. Soon afterwards, the number of tribes and of the Hellanodicks was reduced to eight; but in the 108th Olympiad, they were reſtored to ten, and this number was permanent. The Hellanodicks, from the powers that were veſted in them, acquired great dignity and authority among the ſeveral people of Greece; and in the public execution of their office, they were clothed in purple robes, and carried in their hands, as the uſual enſign of magiſtracy, a wand or ſceptre. They took their ſtations at different parts of the ſtadium, and the ſenior had the precedency of the reſt. The place in which the Olympic games were exhibited was called the *ſtadium*; which ſee. The gymnaſtic exerciſes of which theſe games conſiſted were five (ſee GYMNASTICS); *viz.* the foot-race or *ſtadium*, wreſtling or *palé*, the *pentathlon*, the *cæſtus*, and the *pancratium*; which ſee reſpectively. Thoſe who were competitors in theſe exerciſes were denominated *athletæ*; which ſee. Thoſe who contended in the horſe-races were perſons of higher rank and conſideration than the athletæ; and the ſpectacle itſelf was more pompous and magnificent. There were properly but two kinds of horſe-races at Olympia, *viz.* the chariot-race, and the race of riding-horſes. See the article CHARIOT.

From the nature of the ſeveral exerciſes, of which the Olympic games conſiſted, it is natural to conclude, that every one, who fancied himſelf qualified for obtaining an Olympic victory, was admitted to contend for it. But if it be conſidered that the Olympic games were part of a religious feſtival, inſtituted in honour of the king and father of all the Pagan deities, and ſolemnized with the utmoſt ſplendour and magnificence, by pompous deputations from every ſtate of Greece, that they were attended, either from devotion or curioſity, by a vaſt multitude of people, and that a victory in theſe games was productive of many honours and immunities, we ſhall not be ſurpriſed to find that thoſe, who offered themſelves as candidates for the Olympic crown, were obliged to ſubmit to ſeveral previous conditions, and to paſs through ſuch an examination as would exclude all who ſhould in any degree appear unworthy of the honour of contending for the Olympic olive. Some time before the celebration of the games, they gave in their names to one of the Hellanodicks, and ſpecified the ſeveral exerciſes in which they propoſed to contend. Although the games themſelves laſted but five days, the preparation for them took up 30, which were employed in exerciſing the candidates. The previous preparation was very ſevere, and the exerciſes required were more laborious and intenſe than on any other occaſion. For theſe preparatory exerciſes a particular place was appointed, which was the old Gymnaſium at Elis, where the Hellanodicks attended every day. The candidates took an oath, that they had exactly performed every thing required of them, by way of exerciſe, for ten months, including the 30 days or month ſpent at Elis. On the opening of the games, the names of all the candidates were proclaimed by a herald, and they were required to anſwer the following interrogatories; *viz.* Were they freemen? Were they Grecians? Were their characters free from all infamous and immoral ſtains? The herald, having proclaimed ſilence, laid his hand upon the head of the candidate, and leading him in that manner along the ſtadium, demanded with a loud voice of all the aſſembly, "Is there any one, who can accuſe this man of any crime? Is he a robber or a ſlave? or wicked and depraved in his life and morals?" When the candidate had paſſed with honour through this public inquiry into his life and character, he was led to the altar of Jupiter, ſurnamed "Hercius," derived from *hercos* (ὅρκος), an oath, from his preſiding over oaths. Here the candidates were all ſworn upon the limbs of a boar, ſlain and cut up for that purpoſe, that they would not be guilty of any fraud or indirect action, tending to a breach of the laws relating to the Olympic games. They ſwore alſo to their ten months' previous preparation. Boys, as well as perſons of mature age, were allowed to be of the number of candidates. This was an innovation, introduced by the mere authority of the Eleans, in the 37th Olympiad. However, under the age of 12 years they were reckoned too young, and above 17 they were ranked in the claſs of men.

Ladies were not aſhamed to be reckoned in the number of candidates. For a long time, indeed, they were not ſo much as allowed to be ſpectators of theſe conteſts for glory; and they were liable to the puniſhment of being caſt headlong down the precipices of mount Typæus, if they aſſiſted at the ſolemnity, or paſſed the river Alpheus during the exhibition. The more effectually to reſtrain them, it was ordered that all the maſters of the gymnaſium, who aſſiſted at theſe games, ſhould appear naked, as were alſo all the Olympic candidates; which was without doubt the true reaſon of this law's being firſt made, as well as one of the principal cauſes of its having been ever religiouſly obſerved. It was, nevertheleſs, the peculiar privilege of the prieſteſſes of Ceres to be preſent. As a recompence to the women for their excluſion from the Olympic games, they had a feſtival of their own, inſtituted, as it is ſaid, in honour of Olympian Juno, by Hippodamia, the wife of Pelops. The virgins in this feſtival contended, properly and gracefully clad, in the foot-races; the courſe being ſhortened about one-ſixth part; and the conquereſs received for her reward an olive crown, and a certain portion of the heifer that was on this occaſion ſacrificed to Juno. But the moſt agreeable part of the recompence was the liberty granted to the victorious virgin to have her picture drawn, and hung up in the temple, as a memorial, at the ſame time, of both her beauty and her glory. The direction of this feſtival, and the office of preſiding at theſe games, was lodged in 16 matrons, elected for that purpoſe, two out of each of the eight tribes of the Eleans.

The firſt reward beſtowed upon the conquerors in the Olympic games, and the pledge of many conſequent honours, privileges, and immunities, was a chaplet or crown, compoſed of the branches of a wild olive. (See CROWN.) The laſt duty performed by the conquerors at Olympia was ſacrificing to the twelve gods, who were worſhipped two at one altar, and ſometimes to Olympic Jupiter in particular. Theſe ſacrifices were in ſome caſes performed ſo magnificently, as to entertain the whole multitude aſſembled on the occaſion. Others, leſs able or leſs vain, contented themſelves with entertaining only their own friends, or being feaſted by them, or perhaps by the Eleans themſelves, the ſuperintendants of the Olympic games. At theſe entertainments, a chorus, accompanied with inſtrumental muſic, ſung ſuch odes as were compoſed upon that occaſion in honour of the conqueror. Pindar compoſed odes for this purpoſe; but he demanded a high price for his performances. For perpetuating the glory of theſe victories,

the Hellanodicks entered into a public regiſter the names of the conquerors, with the exerciſe performed, the claſs of men or boys to which they belonged, and alſo the number of the Olympiad. They had alſo the honour of having their ſtatues ſet up in the Altis, or ſacred grove of Jupiter at Olympia. On their return to their own country, they were received with extraordinary tokens of reſpect and applauſe; and it was cuſtomary for the ſacred conquerors to make their entry through a breach in the wall; for which cuſtom Plutarch aſſigns this reaſon, *viz.* that a city which is inhabited by men, who are able to fight and conquer, has little occaſion for walls. The privilege of a public entry was occaſionally granted; but it was reſtricted to few. A ſtipend or ſalary was allotted to the ſacred conquerors by their reſpective cities; and it became due, according to the regulation made by Trajan, from the time of their public entry, and it was continued to them for the remainder of their lives. Another reward conferred upon theſe conquerors was the honour of the firſt ſeat at all public ſpectacles; beſides, they had preſents, and a yearly allowance of proviſions. The laſt privilege we ſhall mention was an immunity from all civil offices, which ſeems to have been owing to the Roman emperors. To the privileges and honours already recited were ſometimes added ſtatues, or other monuments of glory, inſcriptions, and even altars, upon which ſacrifices were offered to them as to heroes or demi-gods.

This celebrated inſtitution of the Olympic games maintained its reputation for a long period, and actually ſubſiſted for more than 1000 years. Its utility, therefore, in a variety of reſpects, muſt be unqueſtionable. It is obvious at firſt view, that this inſtitution excited and maintained ſuch an emulation and ardour to excel in all the various exerciſes which it comprehended, that there was ſcarcely a town of any note, either in Greece or many other countries, in which there was not a gymnaſium, or ſchool of exerciſe, ſupported at the public expence, with a view of training up their youth in a manner that was beſt ſuited, as they conceived, to make them uſeful to their country. The gymnaſtic exerciſes, of which the Olympic games conſiſted, contributed to increaſe the ſtrength and agility of the body, to render them dextrous and valiant in war, to furniſh a ſupply of cavalry when horſes were ſcarce, and the people unſkilful in the management of them, to give employment to thoſe whoſe circumſtances might otherwiſe have made them idle, to induce habits of ſobriety and temperance, (ſee Hor. Art. Poet. v. 412, and alſo 1 Corinth. ix. 25.) to diſcourage vice and immorality, to rouſe into exerciſe and keep alive the love of glory, to cheriſh and preſerve a due regard to the reputation of their families and countries, and to promote concord and union among the different people of Greece. Such are ſome of the principal benefits that reſulted from the inſtitution of the Olympic games. To thoſe who wiſh to ſee them ſtated more in detail, we recommend the peruſal of "A Diſſertation on the Olympic Games," by Gilbert Weſt, eſq. LL.D. For the muſical conteſts at the Olympic games, ſee GAMES.

OLYMPIC *Fire.* See FIRE.

OLYMPICI, GLI, the title of the academiſts of Vicenza, in Italy. See ACADEMY.

OLYMPINION, or NEW ATHENS, in *Ancient Geography*, a town of the iſland of Delos, ſo called by its founder, the emperor Adrian. It contained a temple of Hercules, and another conſecrated to Neptune; which without doubt were magnificent, as Adrian employed only Athenians in the conſtruction of them.

OLYMPIODORUS, in *Biography*, an Alexandrian philoſopher, who flouriſhed about the year 430, is celebrated for his knowledge of the Ariſtotelian doctrine, and was the maſter of Proclus, who attended upon his ſchool before he was 20 years of age. This philoſopher is diſtinguiſhed from a Platoniſt of the ſame name, who wrote a "Commentary upon Plato," which was preſerved among the MSS. in the royal library at Paris; and "A Life of Plato," of which a Latin verſion was publiſhed by Wendet, with learned notes. He is alſo diſtinguiſhed from a Peripatetic of a ſtill later age, who wrote a commentary upon the Meteorology of Ariſtotle. Enfield's Hiſt. Phil.

OLYMPIODORUS, a learned Greek commentator on the Holy Scriptures, who was probably at firſt a monk, and afterwards became a deacon of Alexandria. It is not at all aſcertained with accuracy as to the time when he flouriſhed; ſome placing him in the ninth, others in the eleventh century; but Cave ſays he ought not to be placed later than the early part of the ſixth. He is praiſed for the excellence of his ſermons, with which he edified the church at Alexandria, as well as by the talents which he diſcovered in the elucidations of the ſacred writings. There are extant by him a ſhort "Commentary on Eccleſiaſtes," in Greek and Latin; "A Commentary upon the Lamentations of Jeremiah," publiſhed at Rome, with Origen's Commentary, 1598, 4to.; and "A Commentary upon the Book of Job," the beſt edition of which was publiſhed at London, by Patricius Junius, 1637, folio. Moreri.

OLYMPIONICES, Ολυμπιονικης, in *Antiquity*, an appellation given to thoſe who came off victorious in the Olympic games.

The Olympionices were infinitely honoured in their country, as being eſteemed to have done it immortal honour. The Athenians particularly were ſo laviſh in their preſents to the Olympionices, their countrymen, that Solon found it neceſſary to reſtrain their liberality by a ſpecial law, which imported, that the city ſhould only give 500 drachmas to the Olympionices; which amounted to about 58 ounces of ſilver of our weight. See OLYMPICS.

OLYMPIS, in *Ancient Geography*, a ſtrong place on the Peloponneſus, near the mountains, on the confines of Laconia and the Argolide. Polybius.

OLYMPIUM, a ſmall town of Sicyonia, eaſt of Aſopus, and at a ſmall diſtance from its mouth. It was famous for the tomb of Eupolis, an Athenian poet, mentioned by Horace, as one of the beſt authors in the department of the ancient Greek comedy.

OLYMPUS, in *Biography*. There were two great muſicians in antiquity of the name of Olympus. The firſt was of Myſia, who is ſuppoſed to have been the inventor of the Orthian mode: others give it to the younger Olympus. This was the nome, according to Herodotus and Aulus Gellius, that Arion ſung, when he precipitated himſelf into the ſea. Plutarch ſays, that he was the chief and the maſter of beautiful and ſublime muſic: he excelled in the tender and pathetic. Philoſtratus made him the ſubject of one of his pictures.

OLYMPUS, *Myſian*, lived before the Trojan war, and was the diſciple of Marſyas. Plato, Ariſtophanes, Ariſtotle, and Ovid, cite his verſes. Olympus the Phrygian lived in the time of Midas.

Ariſtoxenus relates that he compoſed, in the Lydian mode, the air for the flute which expreſſed the funereal ſorrows for the death of Python. To him likewiſe are aſcribed the Cerulean, Minervan, Harmatian, and Spondean modes. Plutarch, in his Dialogue on Muſic, informs us that Alexander, in his "Hiſtory of the Muſicians of Phrygia," pretends that Olympus was the firſt who introduced

duced the Greeks to the knowledge of ſtringed inſtruments; and that he inſtituted the cuſtom of celebrating, with the flute, hymns to the polycephalic nome, in honour of the gods.

Plato ſays, that his muſic inflamed his auditors; Ariſtotle, that it exalted the ſoul; and Plutarch, that it ſurpaſſed in ſimplicity all other muſic. Plutarch alſo attributes to him the polycephalic nome, in honour of Apollo; though others aſcribe it to Crates.

Olympus, in *Ancient Geography*, a name given to ſeveral lofty mountains, and thence transferred to the heavens. Le Clerc derives it from "Holamimbo," *immortales in eo;* but the abbé Bergier deduces it from the oriental "Lop," or "Lup," ſignifying *elevation*. According to Heſychius, the number of theſe mountains was fourteen; and ſeven have been particularly noticed by geographers. Homer always diſtinguiſhes Olympus as the habitation of the gods, alluding occaſionally to the mountain which ſeparated Macedonia from Theſſaly, and which was one of the mountains beſt known to the ancients, and deſcribed by European geographers under this name. As Athos (which ſee) aſtoniſhed obſervers by its bulk, Olympus ſtruck the beholder with a kind of reverence by its amazing elevation, and at the ſame time invited his aſcent by the beauty and variety of the proſpects which it afforded. The river Peneus, one of the cleareſt, gentleſt, and moſt beautiful ſtreams in the univerſe, waſhed its foot, dividing it from Oſſa, and making a multitude of ſmall, but delightful iſles, covered with ſhady trees, and adorned with magnificent temples, grottos, porticos, and other ſtately buildings. On the ſouth-eaſt ſide of the hill ran the famous river Helicon, and near it ſtood a noble temple of Jupiter, in the midſt of a ſhady grove. The mountains Oſſa and Pelion were in the neighbourhood, and very conſiderable for their height, though they fell far ſhort of Olympus. Sonnini has particularly deſcribed his aſcent to the ſummit of this mountain. On the ſide of the mountain, and at the firſt ſtage of aſcent, is the village called "Skala;" above which the acclivity, which was below it gentle, becomes rugged and ſteep. In this village is a Greek convent, from which the proſpect is extenſive and magnificent, commanding on one ſide the ſea, the neighbouring coaſts of mount Athos, and the numerous iſlands which diverſify it; and on the other, the beautiful plains of Macedonia. The foreſt by which the monaſtery of Skala is ſurrounded is compoſed of pines, firs, oaks, elms, beeches, hollies, cheſnut trees, &c. and inhabited by wild boars, ſtags, roe-bucks, bears, and birds of different ſpecies. The vicinity is expoſed to the attacks and ravages of Albanian robbers; and Sonnini and his companions eſcaped, by feigning themſelves to be foreign phyſicians, who were in ſearch of plants on the mountain, that would furniſh remedies for a variety of diſeaſes. The aga or commander of the plundering band, labouring under a complaint, applied to them for relief; and thus they avoided the danger to which they were expoſed. In aſcending beyond Skala, our travellers ſtopped at another monaſtery, three leagues from the former: this bears the name of St. Dennis, to whom it is conſecrated. Here the mountain is divided into ſeveral ſteep points, and the building is ſurrounded by thoſe towering pinnacles, that are almoſt entirely compoſed of rocks. In this place are a grotto, or ſmall chapel, ſaid to have been built by St. Dennis himſelf; a hut which ſerved him as a retreat; and at the extremity of the grotto, a ſpring iſſuing from a torrent in the rock, and which, as the fable ſays, the ſaint forced to appear by ſtriking the rock with his cap. The ſmall church of this convent is tolerably handſome; a large beautiful luſtre of bronze, made in Germany, is ſuſpended to the roof. A ſmall library of Greek and Latin books, printed in the ſame country, and well choſen, occupies a chamber of the monaſtery, and being little uſed, will long be preſerved in good condition. Many other articles are brought hither from neighbouring civilized countries, and particularly a large clock, which, though of a common ſort, is an object of admiration in all theſe diſtricts. Above this inſulated convent, ſituated in a very wild place, there are no more habitations on mount Olympus. Our travellers, as they advanced towards the ſummit, ſoon met with large heaps of ſnow; and here the guides waited their return, kindling a large fire, as the cold was very ſharp at this height. Clambering amidſt clumps of trees, and clinging to the branches of ſhrubs, which became ſcarcer as they got higher, and to the projections of rocks, they continued their aſcent, till at length the mount became naked, and preſented only a cap of ſnow and ice, on which it was impoſſible for them to be ſuſtained or walk. "Is it not aſtoniſhing," ſays M. Sonnini, "that the Greeks have placed the abode of the gods on an eminence which mortals cannot reach?" At this time it was the middle of July: the heat was extreme towards the baſe of the mountain, as well as in the plain; and the maſſes of ſnow, which were condenſed near its ſummit, did not appear to be on the point of melting. However it is ſaid, that in the month of September no more ſnow is ſeen on Olympus; an aſſertion which our travellers did not credit, and which was contradicted by the teſtimony of the Greek monks, who have ſucceeded the gods on this great elevation of the globe, and who confirmed what will ſcarcely be doubted, the perpetual permanence of ſnow and ice on the top of the mountain. It is impoſſible, we are told, to conceive the immenſe extent of different countries which a view from the top of Olympus embraces: it ſeemed to touch Pelion and Oſſa, which form another chain of mountains; and the vale of Tempé, which the ancient poets have deſcribed as a place of delight, appeared to be a very narrow gorge; and the river Peneus, which waters it, a ſtreamlet of water ſcarcely perceptible. At the monaſtery of Skala, the temperature is mild, vegetation vigorous, and the number of animated beings greater than the frozen ſummit of Olympus afforded, with the exception of bouquetins, native inhabitants of the rocks, and a few bears. There are hardly any quadrupeds to be ſeen beyond the half of the height of Olympus: ſcarcely do birds paſs this limit. The other ſix mountains which bear the ſame name, are thoſe of Theſſaly, Myſia, Cilicia, the Elide, Arcadia, and the iſle of Cyprus. See Olimpo.

Olympus, a promontory of the iſle of Cyprus, before Carpaſia, where was a temple of Venus *Acræa;* now called "Santa Croce."

The *Myſian* Olympus was a chain of mountains, commencing north of and near to the ſource of the Hermus, and extending from ſouth to north, as far as Bithynia. It bears now the ſame name.

Olympus, a town of Illyria.—Alſo, a town of Aſia, in Pamphylia.—Alſo, a town of Aſia Minor, in Lycia, near the ſea, between Phaſelis and the promontory of Hieron, which did not ſubſiſt in the time of Pliny; though Strabo deſcribes it as a large city, one of the principal towns of Lycia, in the vicinity of a mountain of the ſame name.—Alſo, a mountain of the iſle of Leſbos.—Alſo, a mountain of Lydia.—Alſo, a mountain of Lycia.—Alſo, a mountain of Aſia, near Antandros, and joining mount Ida, &c. &c.

OLYNTHUS, a town of Thrace, in the Paraxia, at the bottom of the Toronæan gulf, between the peninſula of Pallené and Sinthonia. This town was poſſeſſed by the

Greeks, originally from Chalcis of Eubœa. It arrived at a high point of proſperity and grandeur, and had frequent quarrels with Athens, Lacedæmon, and the kings of the latter ſtate, particularly Philip, who deſtroyed it, ſo that it was never completely re-eſtabliſhed. This deſtruction took place in the year 384 B.C.; and from an epigram of Antipater of Sidon, who lived about the year 146 before that era, it appears that it had a kind of renewal, by ſome power of which we have no certain account, nor do we know how long it laſted.

OLYRA, in *Botany*, a name borrowed by Linnæus for the preſent genus, and taken from the ancient ολυρα of Homer, Herodotus, and other Greek authors, amongſt whom it was conſidered to be a fine ſort of *corn* or *grain*, as we learn from the claſſical adjective ολυριτης, (when joined with εγκρυφιας), ſignifying, *bread made of the fineſt flour*. Linn. Gen. 482. Schreb. 624. Willd. Sp. Pl. v. 4. 204. Swartz Obſ. 346. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 325. Juſſ. 33. Lamarck Dict. v. 4. 546. Illuſtr. t. 571. Loureir. Cochinch. v. 2. 551.—Claſs and order, *Monoecia Triandria*. Nat. Ord. *Gramina*.

Gen. Ch. Male flowers beneath the female. *Cal.* Glume ſingle-flowered, of two, equal, lanceolate valves; outer rather ventricoſe, terminating in a capillary, ſtraight, ſmooth awn; inner narrower, acute, folded in on both ſides. *Cor.* none. Nectary very ſmall, of two, obovate, nearly emarginate, membranous, erect leaves. *Stam.* Filaments three, capillary, very ſhort; anthers linear, acute at both ends. Female flowers ſolitary, terminal, in the ſame panicle, much larger than the males. *Cal.* Glume ſingle-flowered, large, ſpreading, of two, nearly equal, ovate, concave, ribbed valves; outer terminating in a long, awl-ſhaped, ſomewhat waved awn, villoſe at the lower part; inner narrower, pointed. *Cor.* Glume of two unequal valves, much ſhorter than the calyx, coriaceous, ſhining, beardleſs, obtuſe. Nectary very ſmall, of three, obovate, membranous, erect leaves. *Piſt.* Germen ſuperior, oblong; ſtyle thread-ſhaped, cloven, almoſt as long as the calyx; ſtigma capillary downy. *Peric.* none, except the hardened glume of the corolla deciduous with the ovate, cartilaginous *ſeed*.

Eſſ. Ch. Male, Calyx-glume ſingle-flowered, awned. Corolla none. Female, Calyx-glume ſingle-flowered, ſpreading, ovate, awned. Glume of the corolla two-valved, beardleſs. Style cloven. Seed cartilaginous.

1. O. *paniculata*. Willd. n. 1. Swartz Obſ. 347. (O. latifolia; Linn. Sp. Pl. 1379. Amœn. Acad. v. 5. 408. Gramen paniceum majus, ſpica ſimplici lævi, granis petiolis inſidentibus; Sloane Hiſt. Jam. v. 1. t. 64. f. 2.)—Stem branched. Panicle terminal.—Native of Jamaica in dry, ſhrubby places, flowering from January to June. *Roots* thread-ſhaped, long, rather thick. *Stem* erect, a fathom high, jointed, round, branched at the lower part; joints ſimple. *Leaves* ſheathing, ſlightly ſtalked, broadiſh-lanceolate, pointed, horizontal, ſpreading, ſmooth, ſtriated; ſheaths downy. *Panicle* terminal, erect, ſpreading, many-flowered, its branches angular, rough, wavy.

2. O. *pauciflora*. Willd. n. 2. Swartz Prodr. 21. Ind. Occ. v. 1. 125. (Gramen floribus axillaribus, foliis ovatis; Loeſl. It. Amer. 243.)—Flowers axillary.—Native of woods in Jamaica, where it flowers in the ſpring. *Roots* very long, capillary, rather hairy. *Stems* aggregate, about a foot high, ſpreading, nearly erect, ſimple, jointed, round, ſlender, ſmooth. *Leaves* ſheathing, alternate, ſtalked, ovato-lanceolate, acute, ſlightly ſtriated, downy, rough at the margin; ſheaths a little hairy. *Flower-ſtalks* lateral from the ſheaths, thread-ſhaped, ſhort, bearing both male and female flowers.

3. O. *orientalis*. Willd. n. 3. Loureir. Cochinch. v. 2. 552.—Stem triangular. Spikes compound. Seeds triangular, rough.—Native of fields in Cochinchina. *Stem* about four feet high, erect. *Leaves* awl-ſhaped, long, partly embracing the ſtem. *Flowers* in compound ſpikes. *Seeds* triangular or roundiſh, white, large.

OLYSSA, in *Geography*, a town of the iſland of Crete. Strabo.

OLZIANY, a town of Lithuania; 30 miles S.S.E. of Wilna.

O'M, among *Hindoo Myſtics*, is a monoſyllable of very profound import. It is ſuppoſed to be a name or an emblem of the Deity, and ſo holy and awful, like the name Jehovah of the Jews, as not to be guiltleſsly pronounced, even by a prieſt. It muſt be contemplated, or recited mentally; and it then is ſaid to excite very efficacious aſpirations. This awful monoſyllable is triliteral, and perhaps therefore better written AUM, for three Sanſcrit letters do in fact compoſe it: but in compoſition, to avoid cacophony, A and U coaleſce in O. The firſt letter is ſuppoſed to be ſymbolical of Brahma, the creative power of the Deity; the ſecond of Viſhnu, the preſerver; and the laſt of Siva, the deſtroyer or renovator: for Hindoo philoſophers maintain that deſtruction is only reproduction in another form. (See SIVA and VISHNU.) As all the inferior deities of the Hindoos are avataras or manifeſtations of, and reſolve themſelves into thoſe three ſuperior powers, ſo thoſe ſuperior powers reſolve themſelves ultimately into Brahm, or the ſupreme being, of whom the ſun is the moſt perfect and glorious murti, or image. (See MURTI.) A combination of the three ſymbolical letters forms, therefore, a hieroglyphical repreſentation of the union of the three powers or attributes, and a word that, if uttered, would be nearly expreſſed by our letters AUM, or OOM, dwelling a little on each letter. A name of Parvati, the conſort of Siva, is Uma, or Ooma, and it is perhaps hence derivable; as well as Omkar, one of the moſt ſacred places of pilgrimage in India, dedicated to the worſhip of this myſterious union. See PARVATI.

In the Inſtitutes of Menu (ſee MENU) many verſes occur denoting the importance of this monoſyllable, and of a text of the Veda cloſely connected with it, called the Gayatri; reſpecting which we ſhall in this article include alſo what we have to offer; together with ſome remarks on ſimilar myſticiſms obſervable in other people. Among thoſe verſes are the following:

Chap. ii. v. 74. "A Brahman beginning and ending a lecture on the Veda, muſt always pronounce to himſelf the ſyllable OM: for unleſs the ſyllable OM precede, his learning will ſlip away from him; and unleſs it follow, nothing will be long retained." A commentator on this verſe ſays, "As the leaf of the *palaſa* is ſupported by a ſingle pedicle, ſo is this univerſe upheld by the ſyllable OM, a ſymbol of the ſupreme Brahm."

76. "Brahma milked out, as it were, from the three Vedas, the letter A, the letter U, and the letter M, which form by their coalition the triliteral monoſyllable, together with three myſterious words, *bhur*, *bhuva*, and *ſwer*." Theſe words mean earth, ſky, and heaven, and are called the vyahritis.

77. "From the three Vedas, alſo, the Lord of creatures, incomprehenſibly exalted, ſucceſſively milked out the three meaſures of that ineffable text, beginning with the word *tad*, and entitled Savitri or Gayatri.

78. "A prieſt who ſhall know the Veda, and ſhall pronounce to himſelf, both morning and evening, that ſyllable, and

and that holy text preceded by the three words, ſhall attain the ſanctity which the Veda confers.

79. "And a twice born man who ſhall a thouſand times repeat thoſe three, (OM, the vyahritis, and the gayatri,) apart from the multitude, ſhall be releaſed in a month even from a great offence, as a ſnake from his ſlough.

80. "The prieſt, the ſoldier, and the merchant, who ſhall neglect this myſterious text, and fail to perform in due ſeaſon his peculiar acts of piety, ſhall meet with contempt among the virtuous.

81. "The great immutable words preceded by the triliteral ſyllable and followed by the gayatri, which conſiſts of three meaſures, muſt be conſidered as the mouth or principal part of the Veda.

82. "Whoever ſhall repeat, day by day, for three years, without negligence, that ſacred text, ſhall hereafter approach the divine eſſence, move freely as air, and aſſume an etherial form.

83. "The triliteral monoſyllable is an emblem of the Supreme, the ſuppreſſions of the breath with a mind fixed on God are the higheſt devotion; but nothing is more exalted than the gayatri."

The ſuppreſſion of the breath is thus performed by the prieſt: cloſing the left noſtril with the two longeſt fingers of the right hand, he draws his breath through the right noſtril; then cloſing that noſtril likewiſe with his thumb, holds his breath while he meditates the text: he then raiſes both fingers off the left noſtril, and emits the ſuppreſſed breath, having, during its ſuppreſſion, repeated to himſelf the gayatri, the vyahritis, the triliteral monoſyllable, and the ſacred text of Brahm. By an ancient legiſlator it is ſaid to imply the following meditation: "OM! earth! ſky! heaven! manſion of the bleſſed! abode of truth! —*We meditate on the adorable light of the reſplendent Generator which governs our intellects:* which is water, luſtre, ſavour, immortal, faculty of thought, Brahm, earth, ſky, heaven." The words which we have diſtinguiſhed by italics are very nearly the gayatri.

Chap vi. v. 70. "Even three ſuppreſſions of breath, made according to the divine rule, accompanied by the triverbal phraſe (*bhurbhuvaswah*), and the triliteral ſyllable (OM), may be conſidered as the higheſt devotion of a Brahman.

71. "For as the droſs and impurities of metallic ores are conſumed by fire, thus are the ſinful acts of the human organ conſumed by the ſuppreſſion of breath, while the myſtic words and the meaſures of the Gayatri are revolved in the mind."

This may ſuffice to ſhew the veneration in which this "myſtic monoyllable" and "ineffable text" are held by Brahmans and Hindoos in general, on the authority of their moſt revered legiſlator Menu. Others of their moſt ſacred books confirm them in this veneration. In the Gita, Kriſhna, deſcribing his own excellencies, ſelects the firſt and beſt of many things wherewith to compare himſelf. "I am," he ſays to Arjun, "the monoſyllable among words." "Amongſt harmonious meaſures I am the Gayatri." See KRISHNA and SRI BHAGAVAT.

The extreme importance that the Hindoos attach to the gayatri, renders it a text of more curioſity than perhaps a general reader will be able to diſcover in the words themſelves, in either their familiar or recondite meaning. It is, like the holy monoſyllable, to be mentally revolved, never articulated. It is taught, as we have ſeen in the preceding extracts from Menu, to the three firſt claſſes, that is, to the Brahman or prieſthood, to the Kſhetriya or ſoldier, and to the Vaiſya or merchant; but not to the Sudra or labourer, nor to individuals of the three firſt-named claſſes, if rendered by vicious propenſities unworthy of the "ſecond birth," promiſed in the holineſs of this myſterious regeneration. Faſting, ablution, prayer, almſgiving, and other commendable acts, are neceſſary preliminaries and accompaniments to initiation in the myſteries of this "ineffable text," which is done by the Guru, or ſpiritual preceptor, in a reverent and ſecret manner. In the Vedas the text occurs ſeveral times, and tranſlations of it by different Sanſcrit ſcholars are given, with many particulars of it and other myſterious points, in the Hindoo Pantheon. "There is no doubt," ſays the author of that work, "but that pious Brahmans would be very deeply ſhocked at hearing the gayatri defiled by unholy articulation, even if expreſſed in the moſt reſpectful manner; and many would be diſtreſſed at knowing the characters, ſound, and meaning, to be in the poſſeſſion of perſons out of the pale of ſanctity. A gentleman on the weſtern ſide of India, unaware of the reſult, began once to recite it audibly in the preſence of a pious Pandit: the aſtoniſhed prieſt ſtopped his ears, and haſtened terrified from his preſence. I ſhould be ſorry, for my own part, if it were revealed ſo as to incur the liability of utterance by inconſiderate individuals, who might thereby wound the feelings of many good and reſpectable men; its promulgation, while probably diſtreſſing to many, would anſwer no deſirable end to ſcience or literature." Page 410. In the frontiſpiece to that work, the character or ſymbol is given that would, if uttered, yield the ſound of OM. The author ſays he once ſhewed it to a Brahman, who ſilently averted his face, evidently pained by what he unwillingly ſaw.

It has been doubted if any except Brahmans were initiated in the ſuppoſed myſteries of this holieſt text. From the extracts given above from the Inſtitutes of Menu, it is clear that the gayatri, ſo far as regarded the words of the text, was taught, with certain exceptions, to three out of the four claſſes or tribes of Hindoos. How far any but Brahmans are initiated in its ſuppoſed myſteries, is another queſtion, and not perhaps eaſily ſolved. But it may be here proper to remark, there is a plurality of gayatris, although their differences have not been hitherto developed. "The white goddeſs, or Saraſwati, preſides over arts and ſciences: ſhe is the Vedas, and the Vedas are in her. (See SARASWATI). Savitri, the conſort of Brahma, is the gayatri, emphatically called the mother of the Vedas. The gayatri conſiſts of certain myſterious words, which are conſidered as the quinteſſence of the Vedas. The three ſuperior claſſes are regenerated, or born again, as they ſay of the gayatri; in the ſame manner that we are born again of the ſpirit and water: and the myſterious name of the holy Trinity is really our gayatri. From this regeneration Brahmans are called Dwija, or twice born. The neceſſity of regeneration is a fundamental tenet among divines in the eaſt as well as in the weſt. There are five different gayatris, according to the number of the principal deities, which are Viſhnu, Siva, the Sun, Devi, and Ganeſa. That of the ſun is the firſt, and belongs excluſively to the ſacerdotal claſs." Aſ. Reſ. vol. xi. art. 2.

Hence it may be reaſonably inferred that there are different degrees of initiation in the free maſonry of the gayatri. That of Surya, or the ſun, with its eſoteric alluſions and meanings, is apparently taught to prieſts only. The powers of creation, preſervation, and renovation, united and ſymbolized in the myſtic OM, appear by the effects produced to exiſt in a peculiar degree in the ſun, and to this object adoration ſeems to have been paid by all people of whom any remote record hath reached us. (See IDOLATRY.) But the Brahmans deny ſuch adoration: affirming that it is to the "incomparably greater Light," typified by the ſun-

that

that their devotions are directed. This indeed the commentaries on the gayatri uniformly confirm. See SURYA.

Sir W. Jones ſays that the gayatri is called the "Mother of the Vedas." This we apprehend is to be taken inductively; the Vedas proceeded from Brahma, or from his ſakti or coequal power or conſort Saraſwati, who is named Savitri, as is alſo both the gayatri and the ſun. In the concluſion of the preface to the Inſtitutes of Menu, is a tranſlation, the words in Italics being thoſe immediately of the text. "The many panegyrics on the gayatri, the mother, as it is called, of the Vedas, prove the author (Menu) to have adored, not the viſible material ſun, but that *divine and incomparably greater light, which illumines all, delights all, from which all proceed, to which all muſt return, and which alone can irradiate* (not our viſual organs merely, but our ſouls and) *our intellects*. Theſe may be conſidered as the words of the moſt venerable text in the Indian ſcripture."

Another tranſlation occurs in the laſt volume of his works, in which he ſeems to have intended making the tranſlation as literal as poſſible.

"The gayatri, or holieſt verſe of the Vedas: Let us adore the ſupremacy of that divine ſun, the godhead, who illumines all, who recreates all, from whom all proceed, to whom all muſt return; whom we invoke to direct our underſtanding aright in our progreſs toward his holy ſeat."

The following paraphraſe or commentary, is by a learned Brahman named Rhadakant, of whom honourable mention is often made by his illuſtrious pupil, the early loſs of whom all lovers of virtue and learning, of oriental learning and literature eſpecially, unite in deploring. "Perfect truth; perfect happineſs; without equal; immortal; abſolute unity; whom neither ſpeech can deſcribe, nor mind comprehend; all pervading; all tranſcending; delighted with his own boundleſs intelligence, not limited by ſpace or time; without feet, moving ſwiftly; without hands, graſping all worlds; without eyes, all-ſurveying; without ears, all-hearing; without an intelligent guide, underſtanding all; without cauſe, the firſt of all cauſes; all-ruling; all-powerful; the creator, preſerver, transformer, of all things.—Such is the great one: this the Vedas declare." The reader may be amuſed and edified by comparing this Brahmanical deſcription of the Deity, with that of ſir Iſaac Newton, given under the article GOD of this work.

We are induced to give another tranſlation of this revered text, together with the prayer which contains it, and that which precedes it, by Mr. Colebroke, the learned preſident of the Aſiatic Society. It occurs in the laſt hymn of the third book of the firſt, or Sama, Veda. This appears to be its proper and original place; for although it occurs alſo in other Vedas, yet here it is included with invocations by Viſwamitra, the ſage or Riſhi to whom it was revealed. (See RISHI and VISWAMITRA.) "This new and excellent praiſe of thee, O ſplendid playful Sun! is offered by us to thee. Be gratified by this my ſpeech; approach this craving mind, as a fond man ſeeks a woman. May that Sun who contemplates, and looks into, all worlds, be our protector.

"*Let us meditate on the adorable light of the divine ruler*—(Savitri).—*May it guide our intellects*. Deſirous of food, we ſolicit the gift of the ſplendid ſun (Savitri) who ſhould be ſtudiouſly worſhipped. Venerable men guided by the underſtanding, ſalute the divine ſun (Savitri) with oblations and praiſe."

The paſſages which we have diſtinguiſhed by italics appear to contain the whole of the gayatri; and with their context are ſufficient to prove that the Hindoos, eſoterically, are not polytheiſts. But it is not eaſy to diſcover why the text ſhould be fancied ſo very profound, or why it ſhould be kept ſecret; for its expoſition, unconnected with the idea of myſtery, does not ſeem likely to have the effect, ſo dreaded by prieſts, of "guiding the intellects" of the multitude to the diſcovery of truth.

We have thus offered, under one article, what we wiſhed to ſay on thoſe two myſterious words *Om* and *Gayatri*. However puerile ſuch myſticiſms may appear to a certain claſs of philoſophers, it cannot be otherwiſe than intereſting to thoſe inquiſitive as to the varieties and coincidences in the human mind, to trace them among remote people and back to remote ages. What is received with myſterious awe by millions of intelligent beings, cannot be wholly undeſerving the ſcrutiny of philoſophy; and where the wiſeſt of refined people diſtant from, and unconnected with, each other, agree in ſuch viſionary reveries, as we may, if we pleaſe, call them, the reſult of an enquiry into their origin and diffuſion may perhaps repay the trouble of reſearch. We ſhall, in this place, however, merely throw out a hint to invite attention on the part of thoſe who have more time and inclination to devote to ſuch points, than we profeſs to have.

As in all languages the letter equivalent to A is the initial, or firſt of the alphabet, ſo, with moſt lettered nations, it has been ſuppoſed to ſignify things primary. Among ancient writers, alpha or aleph was uſed to denote the chief or firſt man of his claſs or rank. By ſome it was applied to Moſes; by many to ſomething myſterious or divine; thence to the Deity. In the ſacred writings we find the Lord ſaying, "I am *alpha* and *omega*, the beginning and the end, the firſt and the laſt." Theſe two letters were hence formed, by myſtical reſearches, into a ſort of hieroglyphic, or ſymbol of the Deity, and afterwards of Chriſtianity, and as ſuch was engraved on the tombs of the early Chriſtians, to diſtinguiſh them from thoſe of idolaters. Thus we find the Hindoo ſacred writings put the ſame words into the mouth of *Kriſhna*, as cited under that article. "I am," he ſays to Arjun, "of things tranſient, the beginning, the middle, and the end." "I am the monoſyllable among words." This monoſyllable OM is the combined alpha and omega of the Brahmas. Without laying any ſtreſs on it, it may be obſerved in paſſing, that thoſe initial and final letters would, combined, yield nearly the monoſyllable ſound in queſtion. Initial and final letters have thus, by poſition, become myſterious with many people. In Sanſcrit the word *agam* contains the important letters, and the word accordingly is found to mean *ſecret, hidden, myſterious*. The Hindoos have an occult work, entitled Agama Saſtra, or Myſterious Ordinances. The ſame work *agam*, or *ogham*, has the ſame meaning, we are told by general Vallancey, in the Iriſh tongue; and in the 14th vol. of the Archæologia, are ſome learned obſervations by the Rev. Stephen Weſton, on the *Ogm*-ian Hercules of Lucian, in which the identity of the Sanſcrit and Iriſh words, and their connection with the obſcure God, is maintained.

The ſimilarity of the languages of the Arabians and Hebrews, and the common origin of the law of thoſe people, lead us to expect a like ſimilarity in their notions, as to the myſterious import of certain letters. Such notions were, and are, of extenſive prevalence among them. We have already ſhewn the myſticiſms of the Hindoos touching firſt and laſt letters, their "triliteral monoſyllable," their "triverbal phraſe," &c. triunities. With the Arabs and Jews the alphabetic initial is the initial and final, the firſt and the laſt, like the alpha and omega of the Greeks, of one their names of God, and is regarded as of peculiar ſanctity. It has occurred to us that the myſterious paſſage in Exodus, אהיה אשר אהיה, hath derived ſome of its myſtic import

port from the common propenſity of mankind to ſee ſomething profound in the form and poſition of letters. Number has, of courſe, as well as form and poſition, a like alluſion; and, of all numbers, *three* and *one* bear the palm of myſticiſm with a curious variety of people. Thus the initial aleph and alpha denoting one, denoted alſo, like the ſingle jod of the Hebrews, and the dot or point of the Hindoos, the unity of the Supreme. Three in combination were very myſtical, either as finals or initials; nor was a medial poſition wholly unimportant. The ש, *ſhin*, exhibiting three jods comprehended in one, was not held to be unmeaning or indifferent. The trident of the weſtern Neptune, and the triſula of the eaſtern Siva, have been ſuppoſed to be connected with the alluſions of this typical letter. This triune emblem denotes dominion over earth, ſky, heaven, the triverbal *bhurbhuvaſwah*, the "great immutable words," as we have ſeen, of Menu, the Hindoo lawgiver.

Without prying farther into theſe fancied myſteries, let us look, for a moment, at the above obſcure text in Exodus, uttered, under awful circumſtances, by the Deity, in unity of perſon. In our verſion it is rendered "I AM that I AM," Ex. iii. 14. The emphatic words are uſually printed in capitals. Paſſing by the meaning of the text, we ſee, in the original, compoſed a triverbal phraſe of triliteral monoſyllables, each of the three words beginning with a myſtic initial of unity, the myſtical letter of triunity being preciſely medial. In other words, one important letter typical of triunity, medially comprehended in one awful triverbal phraſe, compoſed of triliteral monoſyllables all beginning with the thrice-recurring initial of unity.

Here then, in this Jewiſh gayatri, we find the triliteral monoſyllabic-triverbal text, ſo much admired by the Hindoos, and combining all the literal triunities, initial, medial, and final, in every myſtical variety of number, poſition, form, obſcurity, &c. that the moſt enthuſiaſtic, in the pruriency of his imagination, can deſire. We might farther notice the awful letter ת, the initial and final, "the alpha and omega, the firſt and the laſt" of Jehovah, tremendous name! that, like the OM of the Hindoo, no Hebrew would utter, as the final of the *firſt* and *laſt* words of the above "ineffable text," alſo the poſition, &c. of the phraſe "I am alpha and omega, the beginning and the end, the firſt and the laſt," in our ſcripture. It occurs *three* times, and in the *firſt* and *laſt* chapters of the revelation of St. John. But on theſe, and many other ſimilar, and probably, accidental points, that might be hence myſtically "milked out as it were," we have, perhaps, ſaid enough to ſhew why theſe triverbal, &c. phraſes, ſhould have been deemed ſo myſterious by enthuſiaſtic individuals, prone to regard every thing obſcure as myſterious, and every thing myſterious as profound.

It may be doubted if the received tranſlation of the important text in Exodus, iii. 14. be the beſt that could have been adopted. The Hebrew having no preſent tenſe, "I am," conjugatively, ſeems unauthorized by the original. Any literal tranſlation into Engliſh would perhaps be equally liable to objection. "I will be what I have been," to wit, a father, a protector, a God, unto them, has been paraphraſtically ſuggeſted. The concluſion of the verſe, however, appears to imply that אהיה was not meant as any part of the conjugation of a verb. "Thus ſhalt thou ſay unto the children of Iſrael, I AM hath ſent me unto you." The important word in the Engliſh verſion occurs again in capitals. In this ſenſe of a ſacred cognomen many divines have received it. "The Eternal Almighty I AM hath ſent me," was an expreſſion of Whitefield, the enthuſiaſtic itinerant preacher, (Gillies' Life of Whitefield,) and ſhews that he, among others, received it in this light. Joſephus expreſsly ſays that it was not lawful to ſpeak of the name by which God revealed himſelf to Moſes. (See ADONAI). This was believed to have been Jehovah, for which the ancient Jews had a profound veneration; and ſoon after the Babyloniſh captivity it ceaſed to be uttered, its true pronunciation being ſuppoſed to be loſt or unknown. When the ſacred books were read in the ſynagogues, the reader, whenever this ſacred name occurred, did not attempt to pronounce it, but ſubſtituted for Jehovah the other word, which anſwers to the Engliſh word Lord. (See Horſeley's Sermons, vol. iii.) It was reſpectfully alluded to as the Name, the Ineffable Name, the Name of four letters: and in the Talmud curſes are denounced againſt thoſe who ſhould utter it. To try, even, was ſinful. (See JEHOVAH.) This we ſee is in uniſon with the Hindoo prejudices in regard to the unutterable OM, which they pre-eminently call the monoſyllable, the gayatri, the ineffable text, &c.

OM, in *Geography*, a river of Ruſſia, which is of a clear, but black looking water, that runs into the Irtiſch, at Omſk.

OM *el Miſk*, a ſmall iſland in the Red ſea, near the coaſt of Arabia. N. lat. 22° 35'.

OMA, one of the Molucca iſlands, about 9 miles long and 6 wide, containing 11 villages, the principal of which bears the ſame name, and about 5000 inhabitants.

OMACHIS, a river of Canada, which runs into lake St. Pierre. N. lat. 46° 16'. W. long. 72° 42'.

OMAGH, a poſt-town of the county of Tyrone, Ireland, where the aſſizes are held. It is ſituated on the river Cameron, and is nearly in the centre of the county. It was formerly the ſeat of an abbey. It is 86¾ miles N.N.W. from Dublin.

OMAGRA, a name given by ſome medical writers to the gout, when ſeated in the articulation of the humerus with the ſcapula.

OMAGUACA, in *Geography*, a town of South America, in the province of Tucuman; 50 miles N. of St. Salvador de Jugui.

OMAGUAS, a tribe of Indians, inhabiting the banks of the river Amazon, and converted to Chriſtianity in the year 1686, by father Fritz, a Spaniſh miſſionary. They flatten the hinder and fore part of the heads of their children, and thus give them a monſtrous appearance. They treat the people of other nations with ridicule, calling them calabaſh heads.

OMAGUAS, a town at the confluence of the Maranon and Tunguraga, otherwiſe called *St. Joachim*; which ſee.

OMAN, a town of Arabia, capital of a province of the ſame name; 60 miles N.W. of Maſcat. N. lat. 24°. E. long. 57° 20'.

OMAN, a province of Arabia, bounded on the E. by the ocean, on the N. by the Perſian gulf, and on the W. and S. by extenſive deſarts. It is poſſeſſed by a number of petty ſovereigns, the moſt conſiderable of whom is the Imam of Oman, or Maſkat. Several of theſe ſovereigns bear the title of ſcheich. The whole weſtern ſide of Oman is a ſandy plain, a day's journey in length, and extending from the village of Sib to the town of Sohar. The Imam's territories are mountainous to the brink of the ſhore. All the rivers continue to flow throughout the year, except that near which Sohar ſtands; which, traverſing an arid plain, loſes itſelf among the ſands, and reaches the ſea only in the rainy ſeaſon. The country affords plenty of cheeſe, barley, lentils, and different ſorts of grapes. Dates are ſo abundant, that ſeveral ſhip-loads of them are annually exported; and there is a variety of other fruits, and of pulp.

Here are alſo lead and copper mines. Fiſhes are ſo plentiful upon the coaſt, and ſo eaſily caught, as to be uſed not only for feeding cows, aſſes, and other domeſtic animals, but even as manure to the fields. The inhabitants are of different ſects in religion, and mutually regard one another as heretics. The ſubjects of the Imam follow one Muſſulman doctor, and thoſe of the Scheichs another. The territory poſſeſſed by the Imam of Oman is pretty extenſive, and contains ſeveral towns, ſuch as Roſtak, Kalbat, Kiloa, and Sinsjibar; but the moſt important and beſt known city in the dominions of this Imam is *Maſcat*, which ſee. To eke out his ſcanty revenue, the Imam does not himſelf diſdain to deal in trade. He keeps four ſhips of war, and a number of ſmall veſſels, which, in time of peace, he employs in the conveyance of goods, chiefly to and from the eaſtern coaſt of Africa, where he ſtill poſſeſſes Kiloa and Sinsjibar. Some other ſhips are kept to guard the coaſt, which is done ſo negligently or timidly, that pirates venture even into the road of Maſcat. The inhabitants of Oman, although not fond of ſea-fights, are nevertheleſs the beſt mariners in all Arabia. They have ſeveral good harbours, and employ many ſmall veſſels in the navigation between Jidda and Baſra. To the laſt town they ſend annually fifty veſſels, called "Trœnkis," which are ſewed together without nails, the planks being bound with cords. Two numerous tribes of Arabs are chiefly employed in carrying coffee by ſea. One of theſe tribes once inhabited the ſhores of the Perſian gulf; but being haraſſed by turbulent neighbours, they at length ſought refuge in the dominions of the Imam of Oman. Niebuhr.

OMAR I., in *Biography*, the ſecond of the caliphs or ſucceſſors of Mahomet, was diſtinguiſhed, while in a private ſtation, for his love of juſtice, and his zeal for the prophet's authority, of which the following inſtance has been given, though it ſurely deſerves a very different character: a Muſſulman, having a diſpute with a Jew, which was decided againſt him by the prophet, appealed from him to Omar, then in high authority, and held in great reſpect for his integrity and piety. Omar having heard the grounds of the diſpute, deſired the parties to wait a ſhort time, and withdrawing to his houſe, returned with a ſcymitar, and inſtantly clove down the Muſſulman with his weapon, exclaiming, "This is the reward of him who refuſes to ſubmit to the judgment of God and his prophet." It was on this account that Mahomet gave him the appellation of al-farouk, ſignifying both the divider and the diſtinguiſher, thus doubly alluding to his action, and the diſcernment that prompted it. On the death of Abubeker, in 634, he ſucceeded to the office of caliph, and he obtained at the ſame time the title of "Commander of the Faithful," which became that of the ſucceeding caliphs. One of the firſt acts of Omar was to ſuperſede the ferocious but ſucceſsful Caled in the command of the army in Syria; and he reſtored it to Abu Obeidah. (See CALED.) Omar, like his predeceſſor, was the friend to peace, and employed himſelf at home in the civil and religious functions of his office; but his reign was the era of ſome of the greateſt acceſſions made to the Arabian empire, by the conqueſts of its ſeveral chiefs. In Syria, after the capture of Damaſcus, the Moſlem army proceeded to the reduction of Balbec, or Heliopolis, and Emeſſa. The emperor Heraclius having ſent a great force to ſtop the progreſs of the Arabs, it was defeated by Caled in the year 636, at the bloody battle of Yermook. The ſiege of Jeruſalem was the immediate conſequence of this victory. It was bravely defended, but the beſieged having no proſpect of ſuccour, entered upon a treaty of capitulation. One of the articles agreed upon was, that in conſideration of the dignity of this holy city, the object of veneration to Mahometans, as well as to Chriſtians and Jews, the caliph ſhould come and take poſſeſſion of it in perſon. Omar agreed to the propoſal, and his journey has been thus deſcribed: mounted upon a ſorrel-coloured camel, in a tattered habit of hair-cloth, he carried with him his proviſion in two bags, conſiſting of ſodden grain and fruits, together with a leathern ſack filled with water, and a wooden diſh. When he halted to make a repaſt, he permitted any of his ſlender train to partake with him, eating from the ſame diſh. He performed with great devoutneſs all the offices of his religion, and during his march adminiſtered juſtice to all applicants. In ſeveral inſtances, he corrected the laxity of morals which was prevalent among the new converts, eſpecially in matrimonial caſes. On approaching Jeruſalem he was met by Abu Obeidah with an eſcort, and conducted with great reverence into the camp. He there publicly preached to the troops, and rigorouſly aboliſhed many luxurious indulgencies which had gained ground among them. He then ſigned the capitulation, by which the Chriſtian inhabitants of Jeruſalem were ſecured in their lives, properties, and the free exerciſe of their religious ceremonies, but at the ſame time were made tributary, and ſubjected to various humiliating reſtrictions. Omar then made his entry into the city, and viſited the places moſt remarkable for religious antiquities, in company with the patriarch, with whom he converſed moſt freely. Expreſſing a deſire to perform his devotions, the patriarch ſpread a mat for him in the church of St. Conſtantine, but the caliph declined taking advantage of this inſtance of civility, and, inſtead of worſhipping in the church, knelt down on one of the ſteps leading to the eaſt door, in order that he might ſecure to Chriſtians the uſe of their ſacred houſe, well knowing that if he, the caliph, had prayed in it, the Moſlems would ever after have claimed the ſame privilege. He made choice of the ſcite of Solomon's temple for the foundation of a Mahometan moſque, the only one erected by him in Jeruſalem. The converſion of a Jew by his arguments was a circumſtance which he ſaid gave him as much pleaſure as the conqueſt of the holy city. Having regulated the government of Syria, and directed Amru to undertake the reduction of Egypt, the caliph returned to Medina. Aleppo and Antioch were next reduced by the Moſlems, who made themſelves maſters of Paleſtine, and of ſeveral places near the Euphrates. Said, one of the commanders, croſſed the river Tigris, and ſacked the city of Madayn, the ancient Cteſiphon. Syria was at length completely ſubdued, and Amru, now principal commander, proceeded to Egypt, and completed the conqueſt of that country by the reduction of the great and rich commercial city of Alexandria. (See AMRU.) This event, ſays the hiſtorian, gave occaſion to one of the moſt remarkable incidents connected with the name of Omar. Upon an application from Amru to the caliph to know his pleaſure concerning the famous Alexandrian library, an anſwer was returned, commanding its deſtruction; "for," ſaid the caliph, "if the books agreed with the book of God (the Koran), they were ſuperfluous; if they diſagreed, they were pernicious, and ought to be deſtroyed." In conſequence of this horrible deciſion, the manuſcripts were delivered to the five thouſand public baths in the city, to which they ſerved as fuel during the ſpace of ſix months. (See ALEXANDRIAN *Library*.) Under the reign of Omar, Meſopotamia, part of Perſia, Khoraſan, and other remote oriental regions, were reduced to obedience to the Mahometan ſceptre. The days of this caliph were, however, cut ſhort by violence, for in the eleventh year of his reign he received a ſtroke from the dagger of a Perſian ſlave, exaſperated by a deciſion againſt him reſpecting his tribute, which, in the ſpace of three

days, brought him to his tomb, at the age of ſixty-three. He refuſed to nominate a ſucceſſor, but appointed ſix electors to fill the vacant throne. Omar was deeply and deſervedly regretted by the people. His character is thus drawn by Gibbon: ſpeaking of the virtues of his predeceſſor, he ſays, "yet the abſtinence and humility of Omar were not inferior to the virtues of Abubeker; his food conſiſted of barley-bread or dates; his drink was water; he preached in a gown that was in rags: and a Perſian ſatrap, who paid his homage to the conqueror, found him aſleep among the beggars on the ſteps of the moſque of Medina. Economy is the ſource of liberality, and the increaſe of the revenue enabled Omar to eſtabliſh a juſt and perpetual reward for paſt and preſent ſervices to the faithful. Careleſs of his own emolument, he aſſigned to Abbas, the uncle of the prophet, the firſt and moſt ample allowance of twenty-five thouſand drachms or pieces of ſilver. Five thouſand were allotted to each of the aged warriors, the relics of the field of Beder, and the laſt and meaneſt of the companions of Mahomet was diſtinguiſhed by the annual reward of three thouſand pieces. One thouſand was the ſtipend of the veterans who had fought in the firſt battles againſt the Greeks and Perſians, and the decreaſing pay, as low as fifty pieces of ſilver, was adapted to the reſpective merit and ſeniority of the ſoldiers of Omar. Under his reign, and that of his predeceſſor, the conquerors of the Eaſt were the truſty ſervants of God and the people: the maſs of the public treaſure was conſecrated to the expences of peace and war; a prudent mixture of juſtice and bounty, maintained the diſcipline of the Saracens, and they united, by a rare felicity, the diſpatch and the execution of deſpotiſm, with the equal and frugal maxims of a republican government." Univer. Hiſt. Gibbon.

Omar II., the 13th caliph of the race of the Ommiades, ſucceeded his couſin, Solyman, in the year 717. He laid ſiege to Conſtantinople, but was forced to raiſe it, on account of a violent ſtorm, which deſtroyed a great part of his fleet. He was poiſoned at Emeſſa, in Syria, in the year 720. He is characteriſed as having been extremely juſt, religious, and devout, and as one who had fixed his mind, from his infancy, entirely upon another world. He had been extremely economical; but his liberality exhauſted all his revenues, and at his death he had nothing to leave to his ſucceſſors. Univer. Hiſt.

OMARA, in *Geography*, a river on the coaſt of Brazil, which runs into the Atlantic, and whoſe mouth is in S. lat. 5°, and W. long. 36°.

OMARK, a town of Norway; 38 miles N.E. of Frederickſtadt.

OMASUYOS, a juriſdiction of South America, in the government of Buenos Ayres, on the banks of the lake Titicaca. The climate is cold, ſo that it produces little grain, but its paſtures feed a great number of cattle, and it has four gold mines. It has alſo the advantage of a briſk trade, carried on in another juriſdiction by the Indians living on the borders of the lake, who are active and induſtrious in the proſecution of it.

OMBA, a ſmall iſland in the Adriatic, near the coaſt of European Turkey. N. lat. 43° 5'. E. long. 18° 9'.

OMBAY, an iſland in the Eaſt Indian ſea, about 60 miles in length from E. to W., and 18 in breadth. S. lat. 7° 58'. E. long. 125° 7'.

OMBERGAUM, a town of Hindooſtan; 25 miles W. of Poonah.

OMBLA, a river of Dalmatia, which runs into the Adriatic, a little N. of Raguſa, forming at its mouth a conſiderable gulf.

OMBO, a town of Egypt, on the E. coaſt of the Nile; 26 miles N. of Syene.

OMBRE, a celebrated game at cards; played by two, by three, or by five perſons; but generally by three.

The game of ombre is borrowed from the Spaniards, and requires all the phlegm and gravity of that people in the playing.

The name ſignifies as much as the *game of man; ombre*, or *hombre*, in Spaniſh, ſignifying *man*, in alluſion to the thought and attention required in it.

In ombre *by three*, nine cards are dealt to each party; the whole ombre pack being only 40, by reaſon the eights, nines, and tens are thrown aſide: he that wins muſt take five tricks, or four when the other five are divided, ſo as one have two and the other three.

After the cards are dealt, if none of the parties think their hand ſtrong enough to attempt for the ſtake or game, they all *paſs*; and after ſomething put down to the former ſtake, deal over again. If any will attempt for it, he henceforth is called the *ombre*; and the other two become leagued together, like two partners at whiſt, to defend it againſt him.

Note, each has the refuſal of being ombre, according to his order of ſeniority.

There are two ways of undertaking for the game: in the firſt, which is moſt uſual, after chooſing what he will have trumps, he diſcards, or lays aſide, what number of his cards he pleaſes, and in their lieu takes an equal number from the remainder of the pack: the like do the other two. The other way is, when he dare truſt to his own hand, and therefore declines to diſcard, or change any cards, but leaves that to the others, which is called playing *ſans prendre*: if he gains the point, in this latter caſe, he reaps ſomewhat extraordinary, more than in the firſt.

If he fail in either caſe, he is ſaid to be *beaſted*: and the failure is called a *remiſe*, or *repueſte*; and if one of the defenders of the ſtake win more tricks than he, ſuch perſon is ſaid to win *codille*, and takes up the ſtake the ombre played for: and in both caſes, the ombre is to forfeit the value of the ſtake played for to the board.

If the ombre win all the nine tricks, it is called winning the *vole*, and he reaps double; and if he attempt it, and miſcarry, he ſuffers proportionably.

The overſights and irregularities committed in the courſe of the game, are called *beaſts*, and ſubject the perſons chargeable therewith to forfeitures.

As to the order and value of the cards at ombre, it is to be obſerved, that the ace of ſpades, called *ſpadille*, is always the firſt or higheſt trump, in whatever ſuit the trump be: the deuce of trumps, when trumps are either of the black colours, or the ſeven, if of the red, is the ſecond trump, and called *manille*; the ace of clubs, called *baſto*, the third; and if either of the red ſuits be trump, the ace of that ſuit, called *punto*, the fourth. The reſt in the black ſuits are valued according to the following order; *viz.* king, queen, knave, ſeven, ſix, five, four, and three. In the red ſuits, they follow thus; king, queen, knave, deuce, three, four, five, and ſix.

The three firſt, or principal trumps, are called *matadores*; which have this privilege, that they are not obliged to attend an inferior trump when it leads; but for want of another ſmall trump, the perſon may renounce trumps, and play any other card. Add, that if the three matadores be in the hands of the ombre, in caſe he be beaſted, he is to forfeit for them; or if he gain his point, he is to have a conſideration for them; but for nothing leſs than three. And it muſt be farther noted, that the trumps immediately ſucceeding

ing theſe; *viz.* punto, king, queen, &c. if they be found in the ſame hand with the former, are alſo reputed as matadores, and to be allowed, or forfeited for, like the reſt; and this as low as the ſequence reaches, without interruption.

There are ſome varieties in the manner of playing the game of ombre. Sometimes he who has ſpadille is obliged to play, let his game be ever ſo bad; which is called *forced ſpadille*: ſometimes, when all have paſſed, a perſon undertakes the game on condition of diſcarding or making up his hand, before he names trump; which is called the *gaſcarille*.

In ombre *by five*, which ſome even prefer to that by *three*, as not requiring ſo much attention, only eight cards a-piece are dealt: and five tricks muſt be won, otherwiſe the ombre is beaſted.

Here the perſon who undertakes the game, after naming the trump, calls a king to his aſſiſtance; upon which, the perſon in whoſe hand the king is, without diſcovering himſelf, is to aſſiſt him as a partner, and to ſhare his fate. If between both they can make five tricks, the ombre wins; and then the auxiliary king ſhares the ſpoil; and *vice verſâ*.

If the ombre *venture* the game without calling in any king, this too is called playing *ſans prendre*; in which caſe the other four are all againſt him, and he muſt win five tricks alone, or be *beaſted*. The reſt is much the ſame as by *three*, *mutatis mutandis*.

Ombre *de Soleil*, in *Heraldry*, *ſhadow of the ſun*, is when the ſun is borne in armoury, ſo as that the eyes, noſe, and mouth, which at other times are repreſented, do not appear; and the colouring is thin, ſo that the field may be ſeen through it.

OMBRIA. See Brontia and Ceraunia.

OMBROMETOR, a machine to meaſure the quantity of rain that falls. We have the deſcription and figure of one in Phil. Tranſ. N° 473. p. 12. It conſiſts of a tin funnel, whoſe ſurface is an inch ſquare, a flat board, and a glaſs tube ſet into the middle of it in a groove. The riſe of the water in the tube, whoſe capacity, at different times, muſt be meaſured, and marked, ſhews the quantity of rain that has fallen. See Rain-*gage*.

OMBRONE, in *Geography*, a river of Etruria, which runs into the Mediterranean, 5 miles S. of Greſſetto. N. lat. 43° 47′.—Alſo, a town of Etruria, in the territory of Sienna, at the mouth of the Ombrone.—Alſo, a river of Etruria, which runs into the Arno, 8 miles below Florence.

OMDARRA, a town of Bengal; 27 miles E.S.E. of Nagore.

OMDINAR, a town of Egypt, at the ſeparation of the two great branches of the Nile; 7 miles N.N.W of Cairo. N. lat. 30° 6′. E. long. 49° 3′.

OMEDUNDA, a town of Bengal; 34 miles N.N.E. of Doeſa.

OMEGNA, a town of Italy, in the department of the Gogna; 25 miles N.N.W. of Navarre.

OMELET, or Amlet, a kind of pancake, or fricaſſee of eggs, with other ingredients, very uſual in Spain and France.

Menage derives the word from the Italian *animella, little ſoul*; which, he ſays, the people uſe for the nice bits among the giblets of fowls, &c. uſed for fricaſſees, as livers, hearts, kidnies, gizzards, &c. From whence, by reſemblance, is formed the French *amelette, a fricaſſee of eggs*. Tripod derives the word from αμα, *together*, and λυειν, *to diſſolve, moiſten, mix*. And M. de la Mothe le Vayer, from the French *œuf*, *egg*, and *melez*, *mingled*.

The forms of omelets are various. We meet with farced omelets, omelets with ſugar, omelets of green peas, omelets *à la Turq*, &c.

A noted author in this way preſcribes the following one: the eggs being beaten, are to be ſeaſoned with ſalt and pepper, and then fried in butter made boiling hot: this done, gravy is to be poured on, and the whole ſtrewed with chives and parſley, ſhred ſmall. When one ſide is fried enough, it is to be turned on the other.

OMELLOOR, in *Geography*, a town of Hindooſtan, in Travancore; 6 miles N. of Anjenga.

OMELOVAIA, a town of Ruſſia, in the government of Ekaterinoſlav, on the Dnieper; 60 miles N.E. of Cherſon.

OMELYSIS, a word uſed by Hippocrates, and others of the ancients, to expreſs the meal of barley, crude or not parched. It is recommended, when reduced to the form of a poultice, by boiling in wine and oil, for curing all tumours of the tonſils. It is alſo recommended, mixed in water, to be drank in hæmorrhages of the uterus. Authors of later date have made the word omelyſis ſtand for all ſorts of meal or flour, and ſome for an equal mixture of the meal of barley, linſeed, and fenugreek ſeed, in equal quantities; in medicine uſed for horſes. And Cœlius Aurelianus uſes it frequently for a cataplaſm made either of meal, or bread, and water.

OMEN. The primitive and literal ſignification of this word ſeems to be, a ſign of future events from the language of a perſon ſpeaking, without any intention to propheſy: this meaning of the word is implied in the well-known paſſage of Cicero: "Pythagorei, non ſolum voces deorum obſervarunt, ſed etiam hominum quæ vocant *omina*"

The application and meaning of this term was, however, ſoon extended; and in its ſecondary ſenſe comprehended and ſuppoſed ſigns of future events, or preſages, drawn from things, as well as from the words of men. The third ſenſe, in which it is uſed by ancient writers, is ſtill more comprehenſive as well as common: in this ſenſe, it includes the whole myſtery and practice of augury, as it was purſued on a regular ſyſtem by the Greeks and Romans.

The word omen, in all theſe three ſenſes, is applied to ſigns of future events, drawn from circumſtances neither ſupernatural, nor very extraordinary or uncommon. The ſame principle of the human mind, however, which has led rude or ſuperſtitious and unenlightened men to infer future events from natural and common circumſtances, operated with much more effect, in creating the belief, that ſupernatural and extraordinary events were the preſages of what was to happen. Hence the word omen, in its moſt extended ſenſe, ſignified any portent or prodigy.

The law and proceſs of the human mind, by which the belief of omens is generated, is explained in a moſt clear, ſatisfactory, and philoſophical manner, in the following paſſage of profeſſor Stewart, in his Elements of the Philoſophy of the Human Mind, p. 346, quarto edition.

"This tendency of the mind to aſſociate together events, which have been preſented to it nearly at the ſame time; although, on the whole, it is attended with infinite advantages, yet, like many other principles of our nature, may occaſionally be a ſource of inconvenience, unleſs we avail ourſelves of our reaſon and of our experience in keeping it under proper regulations. Among the various phenomena which are continually paſſing before us, there is a great proportion, whoſe vicinity in time does not indicate a conſtancy of conjunction; and unleſs we be careful to make the diſtinction between theſe two claſſes of connections, the order of our ideas will be apt to correſpond with the one as well as with the other; and our unen-

lightened

lightened experience of the paſt will fill the mind with vain expectations, or with groundleſs alarms, concerning the future. This diſpoſition to confound together accidental and permanent connections, is one great ſource of popular ſuperſtitions. Hence the regard which is paid to unlucky days; to unlucky colours; and to the influence of the planets: apprehenſions which render human life, to many, a continued ſeries of abſurd terrors. Lucretius compares them to thoſe which children feel, from an idea of the exiſtence of ſpirits in the dark.

> " Ac veluti pueri trepidant, atque omnia cæcis
> In tenebris metuunt, ſic nos, in luce timemus
> Interdum nihilo, quæ ſunt metuenda magis."

Such ſpectres can be diſpelled by the light of philoſophy only; which, by accuſtoming us to trace eſtabliſhed connections, teaches us to deſpiſe thoſe which are caſual; and by giving a proper direction to that bias of the mind which is the foundation of ſuperſtition, prevents it from leading us aſtray."

The belief in omens was particularly ſtrong and general among the Greeks and Romans; and there is good reaſon to believe that even the moſt celebrated philoſophers among the former were nearly as much addicted to it as the moſt ignorant and ſuperſtitious of the vulgar. If we lay aſide that extreme fondneſs for diſcovering ſublime, enlightened, and myſtical meanings in the doctrines of Pythagoras, and give proper weight, in eſtimating the character of that philoſopher, to the ignorance and credulity of the times in which he lived, and which muſt have operated, in ſome degree, upon his mind and opinions, perhaps we ſhall be diſpoſed to regard many of the ſymbols (as they are called) which are aſcribed to him, not as embracing and concealing his peculiar doctrines, but as inculcating an ominous obſervance of the things to which they relate. Certainly ſeveral of the following ſymbols wear greatly this appearance. Adore the ſound of a whiſpering wind. Stir not the fire with a ſword. Turn aſide from an edged tool. Paſs not over a balance. Setting out on a journey, turn not back, for the furies will return with you. Breed nothing that has crooked talons. Receive not a ſwallow into your houſe. Look not in a mirror by the light of a candle. At a ſacrifice pare not your nails. Eat not the heart or brain. Taſte not that which hath fallen from the table. Break not bread. Sleep not at noon. When it thunders, touch the earth. Pluck not a crown. Roaſt not that which has been boiled. Sail not on the ground. Plant not a palm. Breed a cock, but do not ſacrifice it, for it is ſacred to the ſun and moon. Plant mallows in thy garden, but eat them not. Abſtain from beans.

Among the Greeks there were many omens connected with their ſacrifices: if the beaſt, intended for this purpoſe, eſcaped the ſtroke, leaped up after it was given, did not fall flat on the ground, or kicked and ſtamped after its fall; or if it did not bleed freely, or appeared to expire with pain or difficulty; theſe were conſidered as unlucky omens. It was alſo deemed unlucky, if the victim went unwillingly to the altar; and every method, likely to anſwer the purpoſe, was followed, in order that it might be induced to nod its head, which was regarded as a token of aſſent: when this could be effected by no other means, it was cuſtomary to pour water into its ear. The wagging of its tail, interpreted as another mark of aſſent, was always regarded as a lucky omen.

Omens were drawn from every part of the victim, but eſpecially from the liver; next to the liver, the heart was moſt obſerved: if this were ſmall, or wrinkled, or if it palpitated much, it was unlucky; and if the victim proved to be deſtitute of a heart, it was a moſt deadly omen. After the heart, omens were drawn from the gall, the lungs, the ſpleen, and the membranes, in which the bowels were encloſed.

But omens were drawn, not only from the victims themſelves, but alſo from the things that were made uſe of at ſacrifices: if the flames immediately caught and conſumed the victim, it was a good ſign; and in order to ſecure this, dry ſticks were always prepared. The nature of the flame was alſo regarded: if it was bright and pure, without noiſe or ſmoke, and if it did not go out till the victim was entirely conſumed, the omen was propitious.

But the principal and moſt numerous omens of the Greeks were drawn from birds; and this ſpecies of divination arrived at ſuch perfection, and gained ſo much credit, that other kinds were paſſed by or little regarded, if not confirmed by it.

When the Grecian augurs, who were employed for the purpoſe of taking theſe omens, made their obſervations, they kept their faces towards the north; the eaſt being conſequently on their right-hand, and the weſt on their left. The omens which appeared towards the eaſt were looked upon as fortunate by all the nations of antiquity, becauſe the ſun, the great fountain of light and heat, and the principal cauſe of fertility and animal comfort, makes his firſt appearance in that quarter: on the contrary, the weſtern omens were conſidered unlucky, becauſe the ſun leaves the world in that quarter.

But though both the Greeks and Romans regarded thoſe omens which were ſeen in the eaſt as lucky, and thoſe which appeared in the weſt as unfortunate, yet as the augurs among the former made their obſervations with their faces towards the north, while the Roman augurs made their obſervations with their faces towards the ſouth; the ſigns that were preſented on the right-hand were regarded by the Greeks as fortunate, and thoſe on the left as unlucky: but among the Romans the reverſe was the caſe. Sometimes, however, the Latin authors followed the Greek cuſtom in their uſe of the word *ſiniſtra*, and apply it to unlucky events.

Birds were conſidered as fortunate, or unfortunate, either from their own nature, or according to the place and manner of their appearance: hence the ſame birds, at different times, were ſuppoſed to foretell different and contrary events.

If a flock of birds of different kinds came flying about any man it was an excellent omen. The eagle was particularly obſerved for the purpoſe of drawing omens: when it was obſerved to be briſk and lively, and eſpecially if, during its ſportiveneſs, it flew from the right-hand to the left, it was one of the beſt omens which the gods could give. Reſpecting vultures there are different opinions, both among the Greek and Roman authors: by ſome they are repreſented as birds of lucky omen, while Ariſtotle and Pliny reckon them among the unlucky birds. If the hawk was ſeen ſeizing and devouring her prey, it portended death; but if the prey eſcaped, deliverance from danger was portended. Swallows, wherever, and under whatever circumſtances they were ſeen, were unlucky birds: before the defeat of Pyrrhus and Antony they appeared on the tent of the former, and the ſhip of the latter, and by diſpiriting the minds, probably prepared the way for their ſubſequent diſaſter.

In every part of Greece, except Athens, owls were regarded as unlucky birds: but at Athens, being ſacred to Minerva, they were looked upon as omens of victory and

ſucceſs. The ſwan, being an omen of fair weather, was deemed a lucky bird by mariners.

The moſt inauſpicious omens were given by ravens; but the degree of misfortune which they were ſuppoſed to porte d depended, in ſome meaſure, on their appearing on the right-hand, or the left: if they came croaking on the right-hand, it was a tolerable good omen; but if on the left, a very bad one.

As the cock, when he is overcome, ſits ſilent and melanch ly, but when he obtains a victory, ſtruts about and crows; his appearance in the former ſtate was looked upon as the preſage of defeat; in the latter ſtate, as predicting victory.

Omens were alſo drawn by the Greeks from other animals beſides birds: bees, it is well known, were eſteemed an omen of future eloquence; but when a ſwarm of them lighted upon an altar, it was a very dreadful omen: this circumſtance happened, according to Appian, before the defeat of Pompey. It is rather ſingular that toads, which are now regarded, even by people of ſtrong and well informed minds, with a conſiderable degree of dread and apprehenſion, were accounted by the Greeks lucky omens; while the hare was conſidered as preſaging diſaſter.

Thunder and lightning were deemed fortunate or otherwiſe, according as they occurred on the right-hand or on the left: when an unlucky omen was given by thunder, it was ſuppoſed to be averted by pouring forth a libation of wine; and in order to deſtroy or avert the malignant influence, when it was ſeen on the left-hand, it was uſual to hiſs and whiſtle at it.

Omens were alſo drawn by the Greeks from things which affected their own perſons; from things external, "that only appeared to men, but did not make any impreſſion on them;" and from ominous words. The moſt remarkable of theſe we ſhall notice.

The palpitations of the heart, the eye, or any of the muſcles, and the ringing of the ears, were ominous: the omen was lucky, if the palpitations were on the right ſide of the body, or the ringing in the right ear. A number of rules were laid down for the purpoſe of aſcertaining whether ſneezing were fortunate, or the contrary. "When Themiſtocles was offering ſacrifices, it happened that three beautiful captives were brought to him, and at the ſame time the fire burned clear and bright, and a ſneeze happened on the right-hand; hereupon, Euphrantides the ſoothſayer embracing him, predicted the memorable victory that he afterwards obtained." Xenophon was appointed general, in conſequence of a ſneeze happening on the right-hand while he was making a ſpeech. If a perſon ſneezed between midnight and the following noon it was fortunate, but from noon to midnight, unfortunate. "If a man ſneezed at table while they were taking it away, or if another happened to ſneeze upon his left-hand, it was unlucky; if on the right-hand, fortunate. If, in the undertaking any buſineſs, two or four ſneezes happened, it was a lucky omen, and gave encouragement to proceed: if more than four, the omen was neither good nor bad: if one or three, it was unlucky, and diſſuaded them from proceeding in what they had deſigned: if two men were deliberating about any buſineſs, and both of them chanced to ſneeze together, it was a proſperous omen." Potter's Antiquities, vol. i. p. 339.

A very numerous and important claſs of omens were thoſe which were drawn from things which preſented themſelves in the way, called by the Greeks Ενοδια συμβολα; the meeting of an eunuch, a black, an ape, a bitch with whelps, a vixen with cubs; a ſnake lying in the road, ſo as to oblige the company to divide; or a hare croſſing the path, were deemed bad omens. Some things were regarded as portending evil conſequences to the huſbandman: if, while he was going to ſow his land, he ſaw a woman at work with her ſpindle, or carrying it uncovered, he anticipated a bad harveſt. If, on the meeting of a public aſſembly, a weazel was obſerved to croſs the path, no buſineſs was done: a moſt curious reaſon is given by Artemidorus for regarding this omen on this occaſion; becauſe γαλη, the Greek word for a weazel, is ισοψηφος to δικη (a public aſſembly, or judgment), *i. e.* the letters in each word ſignify the ſame number, *viz.* 42.

When the Greeks went to ſupplicate the gods to obtain any favour, or to avert any calamity, it was uſual to touch the knees of the ſtatue; if they had hopes, they touched the right-hand; if they were confident of obtaining the object of their prayers, they roſe as high as the chin or cheeks, but in no caſe did they ever touch the left-hand of the ſtatue, as that was deemed unlucky.

Before they ſet out on any military expedition, it was uſual to let fly a dove, which was conſidered as an omen of ſafe return, as that bird is not eaſily induced to relinquiſh its habitation, but when driven away conſtantly returns.

The uttering many words was conſidered as ominous; therefore the Greeks never made uſe of the terms which directly expreſſed *death*, but conveyed their meaning on this ſubject by indirect and ſoftening terms; of which is very remarkable and expreſſive, απογινεσθαι, to which the Latin word *denaſci* anſwers, uſed on the ſame account: inſtead of the word ſignifying a priſon, they uſed one ſignifying a houſe; and they were even careful not to call their deities by their appropriate appellations, if theſe appellations were words of bad omen; they therefore generally addreſſed the furies, Ερινυες, by the names Σεμναι θεαι, or Ευμενιδες.

It was cuſtomary for them to clothe their dead in white garments, whence it was reckoned an unlucky omen, and foretelling death, for a ſick perſon to have white apparel; and if a perſon dreamt of a fire being extinguiſhed during the ſickneſs of any in the ſame family, it was deemed a certain forerunner of death.

Perſons in affliction ſuffered their hair to grow long: to cut or ſhave the hair was a token of joy: mariners, upon their delivery from ſhipwreck, uſed to ſhave themſelves; hence, if they dreamt of having the whole head ſhaved, it was an omen that they would undergo great dangers at ſea, but eſcape from them. The younger Pliny, in one of his epiſtles, mentions that he dreamt he had cut off his hair: and this dream he interprets to ſignify his deliverance from ſome great and imminent danger. Men, however, who were labouring under misfortune, though they did not permit others to ſhave them, ſometimes ſhaved themſelves; hence for a man to dream of ſhaving himſelf was a preſage of ſome great calamity.

It was uſual among the Greeks to bedeck the tombs with flowers, herbs, and ribbands: parſley was eſpecially uſed for this purpoſe; hence it was regarded as a bad omen. As Timoleon was proceeding to reconnoitre the poſition and ſtrength of the Carthaginian army, he was met by a number of mules loaded with parſley; this his ſoldiers conceived to be an unlucky omen; but Timoleon with much ingenuity and preſence of mind converted it, in the opinion of his troops, into an omen of victory, by recalling to their recollection, that, at the Iſthmian games, the Corinthians crowned the victors with chaplets of parſley, accounting it a ſacred wreath: in order to impreſs this interpretation of the omen more ſtrongly on them, he firſt made himſelf a chaplet, and then his captains and all the ſoldiers followed his example. With like addreſs, Epaminondas

nondas converted the bad omen which his ſoldiers drew, from the circumſtance of a ribband that hung on his ſpear being carried by the wind to a Lacedæmonian ſepulchre, into a preſage of the defeat of the enemy, by aſſuring them, that as the ribband had been carried to the ſepulchre of the Lacedæmonians, it muſt portend death to them, and not to the Thebans.

The Greeks were particularly careful not to marry, except at propitious ſeaſons. January was eſteemed the moſt fortunate month; and the marriage was expected to be moſt fortunate, if it were celebrated at the time of full moon. Other things were alſo regarded as ominous reſpecting their marriages; if a pair of turtles appeared during the celebration, it was deemed lucky, and a preſage of domeſtic concord. The crow appearing denoted long life to the married pair, if it appeared with its mate; but if it was ſeen ſingle, ſeparation and ſorrow were portended, whence it was cuſtomary at nuptials for the maids to watch, that none of theſe birds, coming ſingle, ſhould diſturb the ſolemnity. If pregnant women were delivered without pain, and eſpecially if they brought forth twins, it was regarded as a good omen, a convincing proof of chaſtity, and a peculiar mark of divine favour. Soon after the children were born, they were placed in winnowing vans, which were looked upon as omens of their future proſperity and riches.

There were ſeveral modes of averting bad omens; Pliny expreſsly declares, that the force and efficacy of the omen depended upon the perſons to whom they appeared If the omen was taken by the hearer, or ſtruck upon his imagination, it was efficacious; but if neglected, or not taken notice of, it was of no force. Julius Cæſar never was deterred by them from any undertaking: Auguſtus, on the contrary, was remarkably ſuperſtitious, and frequently deſiſted from his deſigns on their account. The moſt effectual mode to avert an omen was either to throw a ſtone at a thing, or to kill it outright, if it was an ominous animal; by this means, the evil which it portended was ſuppoſed to fall upon its own head: if it was an unlucky ſpeech, it was cuſtomary to retort it upon the ſpeaker. At the ſight of a madman, or one troubled with epilepſy, it was cuſtomary to ſpit three times into their boſoms, to expreſs that they held the omen in contempt and averſion. Frequently, however, when the Greeks met an unlucky omen, they deſiſted from what they were doing, and began it anew. Euripides deſcribes a perſon, on hearing an ominous word, throwing the cup out of which he was about to drink upon the ground, and calling for another.

As the omens of the Romans were nearly ſimilar to thoſe of the Greeks, we ſhall only notice ſuch as were peculiar to them. Chickens were regarded as affording ſuch important omens, that a perſon, called *Pullarius*, was expreſsly employed to keep them: omens drawn from them were had recourſe to before commencing an engagement. If the chickens came too ſlowly out of the cage, or would not feed, it was a bad omen; but if they fed greedily, ſo that ſome part of their food fell and ſtruck the ground, it was deemed an excellent omen. In the very early times of the republic, before an army paſſed a river, a kind of auſpices were taken from examining the beaks of birds; but Cicero ſays, this had fallen entirely into diſuſe in his time.

When Cæſar landed at Adrumetum, in Africa, with his army, he happened to fall on his face; this was regarded as a bad omen; but he, not being accuſtomed to pay attention to preſages, and therefore, poſſeſſing great preſence of mind on the occaſion, turned it to the contrary; for taking hold of the ground with his right hand, and kiſſing it, as if he had fallen on purpoſe, he exclaimed, "I take poſſeſſion of thee, O Africa."

Auguſtus, on the contrary, as has been already obſe ved, was remarkably ſuperſtitious. When the Greeks and Romans put on their clothes, the right ſide was ſerved firſt; and, therefore, if a ſervant gave his maſter his left ſhoe firſt, it was regarded as a bad omen. This omen Auguſtus regarded with a peculiarly ſtrong ſuperſtitious dread; and this was much increaſed when one day, his left ſhoe having been put on before his right, he was nearly deſtroyed by a mutiny among ſome of his ſoldiers. He alſo paid particular attention to lucky and unlucky days; he never went abroad upon the day following the *nundina*, nor began any ſerious undertaking on the *nones*. It was, indeed, a general opinion among the Romans, that the days immediately following the *nones*, ides, and kalends, were unfortunate. The emperor Valentinian conſidered the 24th of February, in the biſſextile year, as ſo very unfortunate, that having been choſen emperor on that day, he was afraid to ſhew himſelf in public, leſt ſome evil ſhould befall him. (Ammian. Marcell. lib. xxvi. cap. 1.) The emperor Charles V., on the contrary, regarded that as one of the moſt lucky days. (Bayle, Penſées diverſes, p. 47.) The day on which the Romans ſuffered their memorable defeat from the Cimbrians, was long viewed as a moſt unfortunate day; and no general, if he could poſſibly avoid it, would begin a battle on it. When Lucullus expreſſed his determination to attack Tigranes, king of Armenia, on that day, his officers unanimouſly and ſtrongly oppoſed him; but he perſiſted in his deſign, gave battle, completely routed the enemy, obtained one of the moſt ſignal and important victories recorded in Roman hiſtory, and changed the character of the day from unfortunate to fortunate, as he foretold he would, when his officers endeavoured to diſſuade him from fighting.

The Romans paid particular regard to lucky and unlucky names; at public luſtrations, the perſons who brought the victories, were required to have *bona nomina*, fortunate names; and regard was had to the ſame circumſtance in raiſing their levies: eſpecial care was taken that the firſt man who enrolled himſelf ſhould have a name of good augury; and the cenſors, in taking the cenſus of the citizens, always began with a fortunate name, ſuch as Valerius, Salvus, &c.; and in the adjudication of public property, they began with ſome that had a fortunate appellation, *boni ominis ergò*. Feſtus relates, that the ſcrupulous regard to names of good and bad omens, was ſo minute and exceſſive among the Romans, that the women, during their pregnancy, offered ſacrifices to the goddeſs Egeria, becauſe the name Egeria had a cloſe relation to child-delivery, "quod eam putarent facile fœtum alvo *egerere*."

When Julia, the wife of the emperor Severus, had rendered herſelf infamous by her debauched and profligate courſe of life, her huſband conſoled himſelf for his misfortune, by his belief that her name was one of bad omen; all who had borne this name, in his opinion, having been remarkable for looſe and lewd manners.

The oriental nations carry their belief in, and regard to, omens to as great a length as the Greeks and Romans did. The Perſians have diſtinct and appropriate names for the different kinds of omens: *teryk* ſignifies that kind, by which, by throwing pebble-ſtones or gravel, future events are preſaged: *eyaf*, divination from birds, the flight of which is obſerved as carefully as it was among the Greeks or Romans: *kari* is the name of a bird with a long beak, which the Perſians and Arabians conſider as a bird of good omen, and which they are always glad to meet. If a deer is ſeen

deſcending

deſcending from a mountain, or behind the beholder, it is regarded as an unlucky omen, and to omens of this character the name *kades* is given.

The oriental nations alſo are very attentive to fortunate and unfortunate days; about the middle of February, they celebrate a feaſt in honour of the angel *Iſfendarmuz*, the guardian of the fair ſex; and marriages contracted during this ſolemnity were regarded as peculiarly fortunate. If an Aſiatic, when he is ſetting out on important buſineſs, meets with a perſon whom he ſuppoſes to have an unlucky foot, (*ſhum kudem,*) he immediately returns; and if an involuntary cough or ſneeze interrupt the Mahometans during their ablutions, the whole ſervice is began anew, and that as often as it happens. Before a married man ſets out on a long journey, he twiſts, in a particular manner, two branches of the broom called *retem;* and if, on his return, he finds them ſtill twiſted, it is an omen of the fidelity of his wife; but if they are untwiſted, he regards it as ſuch an unfortunate omen, that nothing will induce him to believe her innocent. By a ſingular mode of augury, they endeavour to foretell the weather; they tie ſome combuſtible matter to the tail of a bullock, to which they ſet fire; if the animal runs up the hill, they conſider it as a ſure prognoſtic of rain. When a Perſian peaſant wiſhes the wind to riſe for the purpoſe of winnowing his corn, inſtead of whiſtling, as is common in different parts of Europe, he rubs and ſcatters into the air a ſpecies of ſaffron, and by this means anticipates what he deſires.

In the eaſt there are certain inſects, the name and ſpecies of which are not well known, which are accuſtomed to utter a mournful and ſolemn hum during the night; whenever they are heard great evil is preſaged.

Tamerlane was very attentive to lucky and unlucky days; and he ſeldom put his army in motion, and never engaged in battle, till the aſtrologers had fixed the fortunate hour: an idiot having once thrown a breaſt of mutton at him, while he was planning the conqueſt of *Kharezme*, ſometimes called the *breaſt of the world*, he interpreted it before all his army as an infallible omen of his ſucceſs.

The ancient Germans made much uſe of the horſe in their omens; theſe animals, eſpecially ſuch as were white, were kept at the public expence, and not allowed to be worked for the uſe of man; the preſages were drawn from the mode and time of their neighings. When they were about to engage in any military enterpriſe, they ſet up three rows of ſpears, each row conſiſting of a certain number fixed in the ground, and one laid acroſs the top: when they were thus fixed, a horſe was brought out by the prieſt, and led to the ſpears; if he advanced in ſuch a manner, that his right foot reached the ſpears firſt, the omen was fortunate; but if his left foot advanced before his right, the omen was unlucky: this ceremony was repeated before each of the rows of ſpears; it was alſo obſerved before they embarked on any naval expedition. When the northern nations were converted to Chriſtianity, and indeed for a conſiderable time afterwards, they were ſo devoted to this and ſimilar ſuperſtitions, that a decree of one of the councils expreſsly treats *de auguriis vel avium, vel equorum, vel boum ſtercore, vel ſternutatione.*

Women were appointed by the ancient Germans, as well as men, to obſerve the omens; and one of the moſt ſingular to which they paid eſpecial attention, was derived from obſerving the motions and eddies of a ſtream of water.

Formerly, in Iceland, if a lambent flame was obſerved on the ſurface of the ground, a circumſtance by no means uncommon in that country, it was regarded as a good omen; hidden treaſure was believed to lie in the ground where the flame was ſeen.

A moſt barbarous and inhuman mode of preſaging future events was practiſed among the Scandinavians; they ſacrificed human victims for the expreſs and ſole purpoſe of knowing what was to happen, by the inſpection of their entrails, by the effuſion of their blood, and by the greater or leſs degree of celerity with which they ſunk to the bottom of the water; when the laſt mode was followed, the victim was thrown into a deep well in the neighbourhood of the temple, in honour of *Goya*, or the earth; if he went at once to the bottom, the omen was good; but the reverſe, if he ſwam a long time on the ſurface. If, when the victim was burnt, the ſmoke aſcended very high, it was regarded as a moſt fortunate omen.

The number three, and its combinations, was regarded as uncommonly fortunate by the Scandinavians, as it was, indeed, by other ancient nations, and as it ſtill is amongſt us. Every ninth month they renewed their moſt ſolemn ſacrifices, which were to laſt nine days, and on every day nine living victims, men or animals, were to be offered up. When Olug Nuvin, the youngeſt of Jenghiz Khan's ſons, as maſter of the houſhold, preſented his eldeſt brother with a cup of wine, all the people, hailing him emperor, made nine genuflexions to him, as their ſovereign, and three to the ſun; the number nine was, indeed, in great veneration among the Tartars; when they made preſents to their princes, the number of them was always nine: this number, and its combinations, was always attended to at their feaſts, in their diſhes and ſkins of wine; and even the roving Tartars robbed the caravans by this rule, and would rather take nine of any thing than a greater number. The old Iriſh, in the elections of their *taniſts*, uſed to deliver a wand to him whom they meant to raiſe to that dignity, he having previouſly aſcended a high ſtone; and as ſoon as he had received the wand, he deſcended and turned himſelf round, thrice forward and thrice backward.

But to return to the Scandinavians; they as well as all the other northern nations paid great attention to particular days, and eſpecially to the age of the moon; if poſſible, they avoided engaging in battle before the new moon; and the moon, when new or full, was regarded as the moſt auſpicious for all enterpriſes. The Anglo-Saxons had their lucky and unlucky days for bleeding. Theodore, the monk, taught them that it was dangerous to bleed when the light of the moon and the tides were increaſing; and he pointed out the particular hours of the day when it might be done with ſafety and advantage. The reaſon, if reaſon it can be called, of conſidering the increaſing moon as propitious in ſome caſes, and the waning moon as propitious in others, will be ſtated, when we come to treat of the omens of the Highlanders.

Indeed, among the Anglo-Saxons, as among the Greeks and Romans, every day in every month was propitious or unpropitious for ſome action or another; and thunder, lightning, the new moon, and new year, were lucky or not, according to the day on which they happened. Among the Druids, the ſixth day of the moon was conſidered as a moſt propitious day for embarking on any undertaking, or beginning a journey.

As the manners and cuſtoms of the ancient Britons were derived from thoſe of the Scandinavians, or Celts, their ſuperſtitious ideas, with reſpect to omens, were ſo nearly the ſame, that they need not be detailed. It may, however, be remarked, that the hare was much employed by the ancient

Britons

Britons for the purpoſes of augury, and it was therefore interdicted at table.

In the firſt ages of Chriſtianity, the belief in omens was very prevalent and ſtrong. Ambroſe, Noy biſhop of Noyon, Chryſoſtom in his Homilies, Baſil, Auguſtin, and others, inveigh bitterly againſt it; from their account, the omens, in which the firſt Chriſtians put faith, were very ſimilar to thoſe which prevailed among the Greeks and Romans; ſneezing under certain circumſtances; meeting on the road a cat, a dog, a woman of bad character, a perſon with one eye, or a lame perſon; ſtumbling againſt any thing, or when one was going out of the houſe, being held back by the cloak catching any thing; the palpitation of an eye or muſcle; and innumerable other omens, are mentioned and reprobated by theſe fathers.

Perhaps no change that has taken place within theſe laſt fifty years, is greater or more ſtriking, than that which has gradually been effected in the ſuperſtitious belief of the common people in this kingdom, and probably, though not to ſuch a great degree, in the other kingdoms of Europe. In the middle of the laſt century, the belief in fairies, witches, omens, and ſuperſtitious powers and practices, prevailed, almoſt univerſally, among the lower orders of the community, and even had faſt hold on many of a ſuperior rank and condition of life, eſpecially in the country. Now this belief is ſcarcely found, except among very old people, and in very remote places; and where it does exiſt, it is regarded by the generality of the lower claſs in its proper light. The following enumeration of lucky and unlucky omens, therefore, has reference, rather to popular belief, about the beginning or middle of the laſt century, than to the preſent time; except, as has been already ſtated, in remote places, and among old people.

It appears to have been the popular belief in this country, (though probably prior even to the period we have mentioned) that one of the moſt unlucky omens that could poſſibly happen, was the ſneezing, or the dreams of an old woman; this, no doubt, aroſe from old women being commonly regarded as witches; and it was a common ſaying, that an old woman could believe what ſhe choſe.

In the days when the belief in omens flouriſhed in England, the following were deemed lucky: if, on ſetting out on a journey, a ſow with pigs were met, the journey would be ſucceſsful; to meet two magpies portended marriage; three, a ſucceſsful journey; four, unexpected good news; and five, that the perſon would ſoon be in the company of the great. If, in dreſſing, a perſon put his ſtockings on wrong ſide out, it was a ſign of good luck; but the luck would be changed, if the ſtockings were turned the right way. Nothing could enſure ſucceſs to a perſon going on important buſineſs, more effectually than throwing an old ſhoe after him, when he left the houſe. If a younger ſiſter were married before the elder ones, the latter ſhould dance at her wedding without ſhoes, otherwiſe they will never get huſbands. To find a horſe-ſhoe is deemed lucky, and it is ſtill more ſo, if it be preſerved and nailed upon the door, as thus it prevents witchcraft.

In England, and more particularly in Wales, according to Pennant, it is a good omen, if the ſun ſhines on a married couple, or if it rains when a corpſe is burying. According to the old diſtich,

> "Happy is the bride that the ſun ſhines on,
> Happy is the corpſe that the rain rains on."

There were alſo lucky and unlucky days: according to ſir Thomas Browne, in his Vulgar Errors, there were certain days, when alone, the common people would pare their nails, or have their hair cut; and he adds, that the Romans carefully abſtained from doing theſe things on the *Nundinæ*.

Even yet, Valentine's day is regarded as ominous, in reſpect to marriage, by more than the lower claſſes: and if it rain on St. Swithin's day, rain it will for forty days afterwards. The moon, even by philoſophers, is ſuppoſed to indicate the weather; but the vulgar regard her as foretelling it, much in the ſame manner that other omens preſage future events. If ſhe change in the ſouth-weſt quarter, *i. e.* if ſhe change about four or five o'clock in the afternoon, when the ſun is in the ſouth-weſt, it portends rain; if in the north, or north-eaſt, *i. e.* at that time of the evening when the ſun, if we ſuppoſed him not to ſet, would be in the north or north-eaſt, cold weather is portended. Catholics bleed their horſes on St. Stephen's day, and on the feſtival called Annunciation.

The unlucky omens in England are, to ſee one magpye, and then more; but to kill a magpye is a terrible misfortune. It is alſo unlucky to kill a ſwallow, or more properly the houſe marten. If, on a journey, a ſow croſſes the road, the perſon, if he cannot paſs it, muſt ride round about, otherwiſe bad luck will attend his journey. If a lover preſents a knife or any thing ſharp to his miſtreſs, it portends that their loves will be cut aſunder, unleſs ſhe take a pin, or ſome other trifling article in exchange. To find a knife or a razor portends diſappointment: a piece of coal, ſtarting from the fire, of a hollow form, portends death. To ſpill the ſalt, or lay the knife and fork acroſs each other at table, is very ominous: if there be in company thirteen, which is called the devil's dozen, ſome misfortune will befall one of them. The noiſe of the ſmall inſect called a death-watch, foretells death; and the ſcreech-owl at midnight, ſome terrible misfortune.

If the cheek burns, or the ear tingles, it is a ſign that ſome perſon is talking of one; and the coming of ſtrangers is foretold by what is called "a thief" in the candle. Friday is an unlucky day to be married, and yellow is an ominous colour for an unmarried woman to wear; in plucking a "merry-thought," the perſon who gets the largeſt ſhare will be married before the other.

In the Highlands omens are numerous: it is unlucky to ſtumble at the threſhold, or to be obliged to return for any thing forgot. To ſtep over a gun, or a fiſhing-rod, ſpoils ſport. If, when the ſervant is making a bed, ſhe happens to ſneeze, the ſleep of the perſon who is to lie in it will be diſturbed, unleſs a little of the ſtraw (with which moſt beds in the Highlands were, till very lately, filled) is taken out, and thrown into the fire. If a black cloud, on New Year's eve, is ſeen, it portends ſome dreadful calamity, either to the country, or to the perſon over whoſe eſtate or houſe it appears. The day of the week on which the third of May falls is deemed unlucky throughout the year. Friday is conſidered as unlucky for many things, eſpecially for digging peat, or taking an account of the ſheep or cattle on the farm. Under the perſuaſion, that whatever is done during the waxing of the moon grows, and whatever is done during her waning decreaſes and withers, they cut the turf which they intend for fences, and which, of courſe, they wiſh to grow, when the moon is on the increaſe; but the turf which they intend for fuel, they cut when ſhe is on the wane, as they wiſh it to dry ſpeedily. If a houſe take fire during the increaſe of the moon, it denotes proſperity; if during her wane, poverty. In the iſland of Mull, the firſt day of every quarter is deemed fortunate; and Tueſday is the moſt lucky day for ſowing their corn. The lucky omens in the Highlands are not many, and in general they are the ſame as thoſe in other countries: one, however, ſeems peculiar to them,

them, it is deemed lucky to meet a horſe. In the Orkneys, Friday, which in moſt other places is reckoned an unfortunate day for this purpoſe, is generally choſen for marriage; next to it, Thurſday is fixed upon; and the time when the moon is waxing is the moſt fortunate. When an Orkney fiſherman is ſetting off from the ſhore, he takes eſpecial care to turn his boat in the direction of the ſun's motion; if he neglected this, he would not expect good luck. In the lowlands of Scotland, good or bad fortune throughout the year is thought to depend greatly upon the perſon who is firſt ſeen on New Year's morning, or the "firſt foot," as it is called; if the "firſt foot" be that of a friend, and a fortunate perſon, the ſubſequent year will be fortunate. Under this idea, as ſoon as ever twelve o'clock at night announces the commencement of the New Year, it is cuſtomary, even in Edinburgh, to ſecure a lucky "firſt foot" to one's friends, even though it ſhould be neceſſary to enter their chamber when they are faſt aſleep.

Omen *Prærogativum*, among the Romans, was the vote of the firſt tribe or century in their comitia.

When a law, &c. was propoſed, or an election to be made, an urn was brought in to the prieſts there preſent, into which were caſt the names of the tribes, or centuries, or curiæ; as the comitia were either tributa, centuria, or curiata. And the lots being drawn, that tribe, century, &c. whoſe name came up firſt, was called *tribus*, or *centuria prærogativa*, becauſe their voices were aſked firſt. And ſo much did the Romans depend on this prerogative century, that the reſt generally followed them. Hence a perſon who had the voices of the prerogative was ſaid to have *omen prærogativum*.

OMENTAL Ruptures, in *Surgery*. See Epiplocele and Hernia.

OMENTUM, in *Anatomy*, a part contained in the abdomen, and called in common language the caul. See Epiploon.

OMER, in the *Jewiſh Antiquity*. See Corus.

OMERA, in *Geography*, a town of Arabia, in the province of Yemen; 16 miles N. of Aden.

OMEREE, a town of Hindooſtan, in the circar of Ellickpour; 20 miles S.W. of Ellickpour.—Alſo, a town of Hindooſtan, in Boggilcund; 6 miles W. of Rewah.

OMEREQUI, a town of Peru, in the dioceſe of La Plata; 50 miles N. of La Plata.

OMERGONG, a town of Hindooſtan, in Baglana; 7 miles S. of Damaun.—Alſo, a town of Hindooſtan, in the circar of Aurungabad; 32 miles E. of Aurungabad.

OMERPOUR, a town of Hindooſtan, in the circar of Aurungabad; 40 miles E. of Aurungabad.

OMETEPEC, a river of Mexico, which runs into the Pacific ocean, N. lat. 16° 52′.—Alſo, a ſmall iſland in the lake of Nicaragua; 25 miles E. of Nicaragua. N. lat. 11° 30′. W. long. 86° 6′.

OMEY, an iſland off the weſt coaſt of the county of Galway, Ireland. It appears to have been the ſeat of the pariſh church. N. lat. 53° 31′. W. long. 10° 7′.

OMI, or Oits, a large lake in the iſland of Niphon, 100 miles in length, and 10 in breadth; 15 miles N.E. of Meaco.

OMILPALLAH, a town of Hindooſtan, in the circar of Mahur; 42 miles N.W. of Mahur.

OMISSION, in *Rhetoric*. See Paralepsis.

OMITA, in *Geography*, a town of Hindooſtan in Guzerat; 28 miles E. of Cambay.

OMITTAS, in *Law*. See Non omittas.

OMLI, in *Geography*, a town of Norway; 40 miles N.N.E. of Chriſtianſand.

OMMAGANG, a town of Norway; 48 miles S. of Porſanger.

OMMEN, a town of Holland, in the department of Overiſſel, on the Vecht; 18 miles S.E. of Covorden.

OMMIRABIH. See Morbeya.

OMMO Zaidi, a country of Africa, on the coaſt of Ajan, 70 miles from the ſea, about N. lat. 6°.

OMNES, in the *Italian Muſic*, a Latin term, which we ſometimes find uſed for *tutti*, *all*, or *altogether*.

OMNIUM is a term of finance, denoting all the particulars included in the contract between government and the public for a loan; ſuch as ſtock at three or four *per cent.*, lottery-tickets at a ſtipulated price, annuities for a certain term, &c.

OMO, in *Geography*, a ſmall iſland in the Eaſt Indian ſea, near the E. coaſt of Amboyna. S. lat. 3° 31′. E. long. 128° 51′.

OMOA, or *St. Franciſco de Omoa*, a fortified ſea-port town of Mexico, in the province of Honduras. This is a fortreſs of importance, as it is the key of Honduras, and in time of war, the receptacle of the treaſure ſent from Guatimala. N. lat. 15° 50′. W. long. 89° 53′.

OMÖE, a ſmall Daniſh iſland, in the Great Belt; 10 miles S. of Corſoer. N. lat. 55° 10′. E. long. 11° 10′.

OMOHYOIDEUS, or Omoplatohyoideus, in *Anatomy*, a muſcle of the neck. See Deglutition.

OMOLEY Sinab, in *Geography*, a town of Algiers; 34 miles S. of Conſtantina.

OMOLON, a river of Ruſſia, which runs into the Kolima; 20 miles E.S.E. of Niznei Novimſkoi.

OMONPHON, a ſmall iſland in the Eaſt Indian ſea, near the coaſt of Samar. N. lat. 11° 7′. E. long. 125° 45′.

OMONT, a town of France, in the department of the Ardennes, and chief place of a canton, in the diſtrict of Meziérés; 10 miles S. of Charleville. The place contains 484, and the canton 5151 inhabitants, on a territory of 107¾ kiliometres, in 13 communes.

OMOPHAGI, formed of ωμος, *crude*, and φαγω, *I eat*, among the ancient geographers, a name given to certain nations who fed on raw fleſh, as the Scythians, &c.

OMOPHORIUM, formed from ωμος, *ſhoulder*, and φερω, *I bear*, a little cloak, anciently worn by the biſhops over their ſhoulders, thereby to repreſent the good ſhepherd, who brings home the ſtrayed ſheep on his ſhoulders.

For this reaſon the omophorium was put off at the opening of the Goſpels; becauſe then the true ſhepherd, Jeſus Chriſt, was ſuppoſed preſent in perſon.

Some confound the omophorium with the pallium worn by the patriarchs; but there was this difference, that the pallium was a long cloak of purple, and was peculiarly reſerved for patriarchs; though ſince given to ſome biſhops, by way of diſtinction.

OMOPLATA, in *Anatomy*, from the Greek ωμοπλατη, the ſcapula.

OMPANORATE, an appellation given to the prieſts of the iſland of Madagaſcar.

Theſe are the ſchoolmaſters of the country, and teach Arabic and writing. They have ſeveral books, but none of them contain more than ſome chapters of the Alcoran, and a few phyſical recipes.

They are divided into ſeveral orders, bearing ſome reſemblance to our eccleſiaſtical dignities; as *ombiaſſe*, ſecretary or phyſician; *tibon*, ſubdeacon; *mouladzi*, deacon; *faquihi*, prieſt; *catibon*, biſhop; *lamlamaha*, archbiſhop; *ompitſiquili*, prophets or diviners; *ſabaha*, calif, or the chief of the religion.

The ompanorates deal much in taliſmans, and other charms, which

which they call *hitidzi*, and which they ſell to the grandees of the place. They alſo make little ſtatues, or images, called *auli*, which they conſult as oracles, and to which they aſcribe various powers; as the making rich, deſtroying enemies, &c. They have public ſchools, where they teach their ſuperſtitions and ſortileges.

The *ompitſiquili* practiſe geomancy, and are moſtly conſulted on diſeaſes, and the ſucceſs of affairs; reſolving all queſtions by figures drawn on a little table covered with ſand.

OMPHACION, ομφακιον, derived from ομφαξ, *unripe grape*, in *Pharmacy*, the juice of ſour or unripe grapes.

Some have alſo given the name to a kind of oil, pretended to be drawn from olives, while yet green and ſour. But Pomet charges it as an impoſture, adding that olives yield no oil at all till perfectly ripe.

OMPHACITIS, a name given by naturaliſts to a ſmall ſort of gall of the oak.

OMPHACOMELI, a ſort of oxymel made of the juice of unripe grapes and honey.

OMPHALEA, in *Botany*, a name altered by Linnæus, the genus having been originally called *Omphalandria*, in Browne's Hiſtory of Jamaica, p. 334. The word is derived from Ομφαλος, and alludes to the umbilicated ſhape of the anthers.—Linn. Gen. 479. Schreb. 657. Willd. Sp. Pl. v. 4. 569. Swartz. Prodr. 95. Obſ. 349. Mart. Mill. Dict. v. 3. Juſſ. 392. Lamarck Dict. v. 4. 548. Illuſtr. t. 753. Aubl. Guian. 842.—Claſs and order, *Monoecia Monadelphia*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juſſ.

Gen. Ch. Male Flowers, *Cal.* Perianth inferior, of four or five ovate, ſpreading leaves, the two oppoſite ones larger, convex, coloured. *Cor.* none. Nectary of four glands; making a fleſhy ring round the filament. *Stam.* Filament columnar, thick, ſhort; anthers two or three, oblong, incumbent, connate at their tops, bearing pollen at their edges; when there is a ſingle anther, it is convex or flat and three-cleft. Female Flowers in the ſame cluſter with the males. *Cal.* Perianth inferior, of five leaves, three of them larger, ovate, ſurrounding the germen. *Cor.* none. *Piſt.* Germen ſuperior, roundiſh, very ſhort; ſtyle none; ſtigma three-cleft, broadiſh, obtuſe. *Peric.* Capſule oblong or roundiſh, fleſhy, obtuſely triangular, of three cells and three valves. *Seed.* Nuts ſolitary, ovate, hard.

Eſſ. Ch. Male, Calyx of four leaves. Corolla none. Nectary a fleſhy ring. Filament columnar, the anthers inſerted into it. Female, Calyx of five leaves. Corolla none. Stigma three-cleft. Capſule fleſhy, three-celled. Nuts ſolitary.

1. O. *diandra*. Linn. Sp. Pl. 1377. Aubl. Guian. t. 328. (O. cordata; Swartz. Prodr. 95. Obſ. 350. Omphalandria fruteſcens diffuſa, foliis amplioribus ovatis, petiolis biglandulis, racemis terminalibus; Browne Jam. 334.) —Cluſters compound, leafy, terminal. Leaves ſcattered, heart-ſhaped, villoſe beneath, biglandular at the baſe. Stem climbing.—Native of rocky, ſhrubby ſpots in Jamaica, and other parts of the Weſt Indies. *Stems* ſhrubby, roundiſh, downy, rather divided and diverging. *Leaves* alternate, ſtalked, heart-ſhaped, pointed, coriaceous, thick, entire, ſmooth, downy beneath; footſtalks long, lax, biglandular. *Stipulas* ſmall, lanceolate, deciduous. *Cluſters* terminal, compound, branched, diverging, looſe. *Bracteas* lanceolate, obtuſe, ſmooth, placed at the baſe of each ſimple cluſter of *flowers*, which are numerous, ſmall and green. *Capſule* yellowiſh, containing three brittle *nuts*, with oblong angular *kernels*.

2. O. *triandra*. Linn. Sp. Pl. 1377. Amoen. Acad. v. 5. 408. (O. nucifera; Swarts. Prodr. 95. Obſ. 351. t. 10. f. 6. Omphalandria foliis obovatis glabris, ad baſin biglandulis; floribus triandris; Browne Jam. 335, but not his t. 22. f. 4, according to Swartz.)—Cluſters compound, leafy, terminal. Leaves oblong, biglandular at the baſe. Stem arboreous.—Native of woods in Jamaica, and not unfrequently cultivated there. This *tree* is from twelve to fifteen feet high, erect, with a ſmooth bark. *Branches* ſpreading horizontally, deflexed and rather divided. *Leaves* alternate, ſtalked, elliptically elongated, ſcattered, drooping, attenuated, and bearing two glands at the baſe, obtuſe at the end, entire, ſmooth, ribbed; footſtalks deflexed, long, roundiſh, ſmooth. *Cluſters* terminal, amongſt the leaves, ſolitary, compound, drooping, lax. *Nuts* very hard, black, their kernels white, ſurrounded with a yellow membrane. The nuts, which are highly flavoured, are eſculent; and the ſtalks and branches emit an aqueous fluid. The Engliſh at Jamaica call this tree *Cobnut*, and the French *Noiſettier*.

We think the reaſon given by Swartz for changing the Linnæan ſpecific names of the above two ſpecies, is by no means ſatisfactory, as his other two diandrous ones are now made a new genus, *Epiſtylium*, in his Fl. Ind. Occ. 1095.

OMPHALOBIUM, ſo called by Gærtner, from ομφαλος, *the navel*, and λοβος, *a pod* or *legume*, is, if we miſtake not, no other than *Connarus monocarpus* of Linnæus. Juſſieu perceived its affinity to *C. africanus*; ſee his Gen. 453, and Gærtn. t. 46. The name alludes to a depreſſion on each ſide of the ſcar, or *umbilicus*, of the ſeed.

OMPHALOCELE, from ομφαλος, *the navel*, and κηλη, *a ſwelling*, a term in *Surgery*, ſignifying a rupture of the navel. See Hernia.

OMPHALODES, in *Botany*, ομφαλωδης, from ομφαλος, *the navel*, was adopted by Tournefort for the name of a genus which he founded upon ſome plants referred by Linnæus, perhaps not correctly, to Cynoglossum; ſee that article. The plants in queſtion are very remarkable for the umbilicated form of their ſeed-caſes, and in other reſpects differ greatly from *Cynogloſſum*.

The ſame word is retained as the ſpecific appellation of a *Lichen*, to which it is by no means excluſively ſuitable, though taken from its characteriſtic denomination in Vaillant. The term is equally applicable to the ſhields of a great number of neighbouring ſpecies, at ſome period or other of their growth.

OMPHALOMANTIA, a word uſed by ſome authors to expreſs a ſort of divination pretended to by the midwives and old women, of telling how many more children a woman is to have, by examining the number of knots on the umbilical cord.

OMPHALOPTER, or Omphaloptic, in *Optics*, a glaſs that is convex on both ſides, popularly called a convex lens.

OMPHALOTOMIA, from ομφαλος, and τεμνω, *to cut*, the operation of dividing the navel-ſtring.

OMPHALUS. See Enteromphalus, Exomphalus, and Hydromphalus.

Omphalus, in *Natural Hiſtory*, a term uſed by the ancients to expreſs what they at other times call *umbunculus* in ſtones; that is, a ſmall round and prominent ſpot, in the centre of the ſtone.

The zmilampis, which was a kind of oculus beli found in the Euphrates, had uſually a blue prominent pupil, and this was called omphalus, and umbunculus, indifferently, and ſo in other ſtones. The words have both the ſame origin, and are uſed to expreſs its being like the button, or prominent piece, in the middle of a ſhield called by the Greeks *omphalos*, and by the Latins *umbo*.

OMPHAX, the name the ancients gave to a gem of the

pellucid kind, and of a diſagreeable greeniſh colour, with a mixture of yellow. Pliny, and ſome other old writers, make this a kind of the aqua marine, calling it the *berillus oleaginus*; but the earlier writers very juſtly determined it not to be of the beryl kind, but properly a diſtinct ſpecies of gem; and therefore very properly called it by a peculiar generical name.

OMPOMPANOOSUCK, in *Geography*, a furious but ſhort river of Vermont, which, after purſuing a S.W. courſe, diſcharges itſelf into the Connecticut at Norwich, oppoſite to Dartmouth college.

OMPTAH, a town of Bengal; 21 miles W. of Calcutta

OMRAUTTY, a town of Hindooſtan, in the country of Berar; 20 miles S S.E. of Ellickpour. N. lat. 20° 55′. E. long. 78° 16′.

OMSK, a town and fortreſs of Ruſſia, in the government of Tobolſk, on the river Om, when it unites with the Irtiſch, built in 1716, and well garriſoned. N. lat. 55°. W. long. 74° 54′.

OMTCHOU, a river of Thibet, which runs into the Nitchon, near Tarendſang.

OMTRAGER *la Lumière* of a pipe, in *Organ Building*, is ſoldering to the ſides of the mouth two ſmall plates of the ſame metal; theſe plates are called *ears*. By opening and cloſing theſe ears, pipes of this kind are tuned.

OMURA, in *Geography*, a town of Japan, in the iſland of Ximo; 15 miles N.N.E. of Nangaſaki.

OMY, in *Agriculture*, a provincial term employed to ſignify mellow, when ſpoken of land. It is often written *oamy*.

ON, in *Scripture Geography*, called alſo *Onion* and *Onium*. See HELIOPOLIS.

There were two cities of the ſame name, the one, as Pliny terms it, interior, and the other without, of leſs note, really ſituated in Arabia, and modern in compariſon with the former. It lay to the E. of the Nile, and to the S. of the Arabian canal, at the diſtance of 12 miles from Babylon, and 24 from Memphis. It is mentioned, ſays the learned Bryant, by ſeveral writers, under the name of Heliopolis; but its true name was Onium, which it received from Onias, the ſon of Onias a Jew, who built it. Onias, as it has been ſaid, having fled from his own country, had a great inclination to build a temple in Egypt reſembling that at Jeruſalem, or rather in oppoſition to it. In effecting his purpoſe, he found great difficulty; and in order to gain the aſſent and aſſiſtance of his brethren, in that part of the world, he had recourſe to a prophecy (Iſaiah xix. v. 18, 19.) which he interpreted as favourable to his ſcheme. According to Scaliger, Onias was led to the choice of the prefecture of Heliopolis for erecting his temple by this prophecy; altering the expreſſion ſo as to render it more favourable to his deſign. His temple, however, was not founded in the nome of Heliopolis; and this name was given to it by a miſtake reſulting from a ſimilitude that ſubſiſted between the true name "Onion," and the ancient "On," or Heliopolis. Of this he availed himſelf, for rendering the paſſage in Iſaiah prophetic of the eſtabliſhment of his temple. The name indeed was given to it after it was built, and the prophecy was uſed to ſupport what was done rather than to promote it, ſo that there ſeems to have been a colluſion between Onias and thoſe of his party, to impoſe this name upon the place; in order that it might be entitled to the benefit of the prediction. This is plain from the LXX, (Exod. i. 11.) where the words "On, which is the city of the Sun," are interpolated, in order to ſupport the pretenſions of Onias, and to prove that this was the name of the place which he had founded. According to this account, the city of Onias is ſaid to have been built when the Iſraelites had reſided ſome time in Egypt; for they are preſumed to be the builders; but there was another of the ſame name, the ancient On, previouſly mentioned in the ſame tranſlation; and was prior to their coming into theſe parts. It is ſaid that Joſeph, before the coming of his brethren, had married the daughter of the prieſt of On, at the recommendation of Pharoah, which On, the LXX very properly tranſlate Heliopolis. (See Gen. xli. 45.) Notwithſtanding the account given by Joſephus (Antiq. lib. xiii. c. 3.) of the temple of Onias, and the occaſion of its being built, Bryant conceives that the place allotted to him for this purpoſe was not Heliopolis, but Onium, the ſituation of which was exterior with reſpect to Egypt; and this was ſo ſimilar to the ancient On or Heliopolis, that it obtained that name; a name which it never received till after it was built; and then the prophecy was made uſe of by Onias and his friends to eſtabliſh the temple when finiſhed, and to ſanction their proceeding. Afterwards the Greeks in Egypt, hearing that the chief temple of the Jews was called Ονιον or Onium, imagined that this name was derived from ονος, ſignifying an aſs; and hence they concluded that they had diſcovered the ſecret object of the Jewiſh worſhip. This notion was ſoon propagated; and it was aſſerted, that in the veſtibule of every Jewiſh temple there was an aſs's head. This fable was, in proceſs of time, extended even to the Chriſtians, and they were denominated Aſinarii, and charged with having an aſs's head in their churches, as an object of worſhip. As this temple was built in imitation of that at Jeruſalem, it did not long ſurvive it. Veſpaſian, it is ſaid, gave orders for its deſtruction; though ſome writers defer the demolition of it to the time of Trajan: the temple upon mount Gerizim having been deſtroyed long before, probably when Hyrcanus took Samaria. See Bryant's Obſervations, &c. Diſſ. iii. p. 124, &c.

ON *the Beam*, any diſtance from the ſhip; or the wind is ſaid to blow, when on a line with the beams, or at right angles with the keel.

ON *the Bow*, an arch of the horizon, comprehending four points of the compaſs on each ſide of that point to which the ſhip's head is directed. Thus, ſeamen ſay, the ſhip in ſight bears three points *on the ſtarboard bow*, that is, three points towards the right hand from that part of the horizon which is right a-head.

ON *the Quarter*. Suppoſe the wind at eaſt, and a ſhip ſailing right before the wind, ſhe would have the wind quartering from north-weſt to ſouth-weſt, for at thoſe two points the wind would be on the ſtarboard or larboard quarter, according to what tack the ſhip was on. See ON *the Bow*.

ON-*Stand*, in *Agriculture*, a provincial term applied to the rent paid by the out-going to the in-coming tenant, for ſuch portions of ground as the former has rightly cropped before his leaving the farm.

ONA, in *Geography*, a river of Ruſſia, which runs into the Uda at Mongalova, in the government of Irkutſk.—Alſo, a town of Peru, in the dioceſe of Lima; 35 miles N.N.E. of Loxa.

ONABAS, a town of New Mexico, in the province of Hiagni; 16 miles N. of Riochico.

ONAGER, in *Zoology*, the name given by authors to the wild aſs, a creature common in Syria, and ſome other places, and differing very little more from the common aſs, than as creatures in their native wildneſs do from thoſe of the ſame ſpecies kept in ſtables, and brought up to be domeſtic animals. The ſkin of this creature is very robuſt and durable, and makes the common ſhagreen leather uſed by

our cafe-makers, &c. its ſurface being rough with ſmall tubercles. See ASINUS.

ONAGRA, in *Botany*. See JUSSIÆA and ŒNOTHERA.

ONAGRÆ, the 88th natural order in Juſſieu's ſyſtem, or the 6th of his 14th claſs, is ſo called from *Onagra*, the Tournefortian name of the Evening Primroſe. (See ŒNOTHERA.) For the characters of this claſs ſee FICOIDEÆ. The *Onagræ* are ranged next to the order laſt mentioned, and characteriſed as follows.

Calyx of one leaf, tubular, ſuperior; its limb divided, and either permanent or deciduous. *Petals* definite in number, inſerted into the upper part of the calyx, alternate with its ſegments. *Stamens* definite, inſerted into the ſame part, either equal in number to the petals, or twice as many, rarely more. *Germen* ſimple, inferior; ſtyle generally one; ſtigma either ſimple or divided. *Fruit* capſular or pulpy, inferior, rarely but half inferior, moſtly of many cells, with numerous ſeeds, rarely of one cell only; ſometimes crowned with the limb of the calyx; ſometimes, from the falling off of that part, naked at the ſummit. *Corculum* without albumen. *Stem* either herbaceous or ſhrubby. *Leaves* alternate or oppoſite.

Section 1. Style manifold. Intermediate genera between the *Onagræ* and *Ficoideæ*.—Here Juſſieu places his *Mocanera* (*Viſnea* of Linn. Suppl.); *Vahlia* of Thunberg (ſee OLDENLANDIA); and *Cercodea* of Solander, which is *Haloragis* of Schreber.

Sect. 2. Style one. Fruit capſular. Stamens equal in number to the petals.—This ſection conſiſts of *Montinia*, *Serpicula*, *Circæa*, and *Ludwigia*.

Sect. 3. Style one. Fruit capſular. Stamens twice as many as the petals.—*Juſſiæa*, *Œnothera*, *Epilobium*, *Gaura*, *Cacoucia*, Aubl. t. 179, *Combretum* and *Guiera*.

Sect. 4. Style one. Fruit pulpy.—Genera akin to the *Myrti*, but differing in the definite number of their ſtamens.—Theſe are *Fuchſia*, *Petaloma* (Mouriria of Aublet), *Ophira*, *Bæckea*, *Memecylon*, *Jambolifera*, *Eſcallonia*, *Sirium*, and *Santalum*.

Sect. 5. Genera akin to the *Onagræ*, but polyandrous *Mentzelia* and *Looſa* (or *Loaſa*).

The learned author of this order has made many ſubſequent remarks and corrections reſpecting it, in the Annales du Muſeum d'Hiſt. Nat. v. 3. 315, where he terms it, according to a new plan of nomenclature, *Onagrariæ*. His paper is tranſlated in Dr. Sims and Mr. Konig's Annals of Botany, v. 1. 530.—Juſſieu here adds to the ſecond ſection *Trapa* and *Lopezia*. He propoſes to remove from the fourth *Eſcallonia*, *Petaloma*, and *Bæckea*, and ſpeaks doubtfully of *Jambolifera*, as not underſtanding the various characters given of the latter by authors, becauſe they have deſcribed different things under that name.—As to the firſt ſection mentioned above, he would remove *Mocanera* or *Viſnea* to his *Guaiacanæ*; and expreſſes juſt doubts concerning *Vahlia*. He rightly refers *Proſerpinaca* with *Myriophyllum* to the neighbourhood of *Cercodia* or *Haloragis*.

It is proper to obſerve that what Juſſieu, in this eſſay, terms the firſt ſection, is, in his Gen. Pl., as above, the third. This he ſays is the richeſt in genera, and he propoſes to make no alteration therein, nor any addition thereto. It is in reality the cleareſt in character and habit of the whole, comprizing the real *Onagræ*, all moſt naturally allied in ſtructure and habit to each other. See the various genera in their proper places.

ONANCOCK, in *Geography*, a town of America, in the ſtate of Virginia. N. lat. 37° 45'. W. long. 75° 46'.

ONANG-SIUEN, a town of Corea; 40 miles S.S.W. of Kang.

ONANIA, and ONANISM, terms which ſome late empirics have framed to denote the crime of ſelf-pollution, mentioned in ſcripture to have been practiſed by Onan, and puniſhed in him with death. Some take it for the ſame with what in other places of ſcripture, particularly Levit. ch. xx. is called *giving of ſeed to Moloch*; for which the puniſhment allotted is ſtoning to death.

This is but ill warranted; the ableſt critics make them quite different things. Selden is poſitive the Jews, in imitation of their neighbours, actually ſacrificed their children to Moloch. Others fancy they only made them paſs between two fires, in order to obtain the idol's favour and protection. See MOLOCH.

ONANO, in *Geography*, a town of Italy, in the Patrimonio; five miles S. of Aquapendente.

ONANS, a town of France, in the department of the Doubs; 12 miles N.W. of Blamont.

ONAPA, a town of New Mexico, in the province of Hiaqui; 40 miles N.N.E. of Riochico.

ONAS, a town of Japan, in the iſland of Ximo; 22 miles S. of Funai.

ONATE, a town of Spain, in Guipuſcoa; 22 miles N.E. of Vittoria.

ONCA, in *Zoology*, a ſpecies of the *felis*, in the Linnæan ſyſtem. See FELIS.

ONCHA, in *Geography*, a town of Hindooſtan, in the circar of Gohud; 18 miles S. of Bandera.

ONCHIDIUM, ONCH, in *Zoology*, a genus of the Vermes Molluſca claſs and order; of which the generic character is as follows: Body oblong, creeping, flat beneath; mouth placed before; two feelers, ſituate above the mouth; it has two arms, at the ſides of the head; the vent is behind, and placed beneath.

There is only one ſpecies, *viz.*

TYPHÆ. This is fully deſcribed in the fifth volume of the Linnæan Tranſactions. It inhabits Bengal, on the leaves of the Typha elephantina; it is about an inch long, and three quarters of an inch broad, but linear and longer when creeping. In appearance it reſembles a limax, but differs principally in wanting the ſhield and lateral pore, and in being furniſhed with a vent behind. The body above is convex, aſh-colour, and covered with irregular glandular tubercles; beneath it is flat and ſmooth; the head is yellowiſh, ſmall, and placed beneath, which, when the animal is in motion, is perpetually changing its form and ſize, and drawn in when at reſt; the mouth is placed lengthways, and is continually varying in its ſhape, from circular to linear; the feelers are retractile, reſembling thoſe of the ſlug, and apparently tipt with eyes; the arms are dilatable, ſolid, compreſſed, and ſomewhat palmate, when fully expanded.

ONCIDIUM, in *Botany*, ſo named by profeſſor Swartz, according to his own account, from ογκιδιον, *a tubercle*, in alluſion to a couple of prominences on the lip. His figure repreſents one of theſe as forming ſo perfect a hook, that we preſume he had in view alſo that ſenſe of the word ογκος.—Swartz. Act. Holm. for 1800. 239. t. 3. f. 2. Orchid. 77. t. 1. f 2. Tracts on Botany, 180. t. 5. Willd. Sp. Pl. v. 4. 112.—Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*, Linn. Juſſ.

Gen. Ch. *Cal.* Perianth of three, rarely but two, ſtalked leaves. *Cor.* Petals two, larger than the calyx, ſomewhat wavy. Nectary a lip ſpreading from the baſe of the ſtyle, lobed; the central lobe large, with two prominences on the upper ſide of its diſk. *Stam.* Anther a roundiſh deciduous lid, of two cells, between the wings of the ſtyle; maſſes of pollen globular, in pairs, joined by a common ſtalk. *Piſt.* Germen inferior, ſlender, nearly cylindrical; ſtyle erect,

excavated

excavated in front, with two marginal wings at the ſummit; ſtigma concave, beneath the anther. *Peric.* Capſule oblong, ſlender, of one cell, opening between the ribs. *Seeds* numerous, minute, tunicated.

Eſſ. Ch. Calyx and petals ſpreading. Lip flat, with tubercles near the baſe. Anther a deciduous lid, between the wings of the ſtyle.

Obſ. This handſome genus is remarkable for the ſingular lobed form of the flower, and the panicled inflorescence. All the known ſpecies are natives of the Weſt Indies.

1. O. *carthagenenſe.* Willd. n. 1. Sw. Ind. Occ. 1479. (Epidendrum carthagenenſe; Jacq. Amer. 228. t. 133. f. 4. Pict. 111. t. 214. E. undulatum; Sw. Prodr. 122. Curt. Mag. t. 777. Viſcum radice bulboſâ majus et elatius, delphinii flore ferrugineo guttato; Sloane Jam. v. 1. 250. t. 148. f. 1.)—Stem none. Leaves elliptical, flattiſh, fleſhy. Stalk radical, much branched. Petals roundiſh, with claws. Lip crenate.—This grows on trunks and large arms of trees in Jamaica. It flowered in May 1804, in Mr. Woodford's collection at Vauxhall. The *root* conſiſts of many thick fibres. *Leaves* a foot long, compared by Sloane to thoſe of the common White Lily. *Stalk* three to ſix feet high, much branched above, the ultimate branches bearing ſeveral large, alternate, nearly ſeſſile *flowers* towards their extremities. The *calyx* and *petals* are ſomewhat ſpatulate, whitiſh or yellow, variegated with ruſty brown and purple; the latter larger, paler, more wavy, and veiny. *Lip* of the ſame colours, with a ſmall violet-coloured diſk.—Swartz in his *Flora* puts a mark of doubt to the ſynonym of Jacquin. The colours of the *flowers* in the Bot. Mag. are more lurid, and apparently more natural than in Jacquin's figure.

2. O. *altiſſimum.* Willd. n. 2. Swartz. Ind. Occ. 1481. (Epidendrum altiſſimum; Jacq. Amer. 229. t. 141. Pict. 112. t. 215.)—Stem none. Leaves elliptic-lanceolate, bulbous at the baſe. Flowers in a long compound cluſter. Calyx and petals lanceolate. Lip emarginate.—Paraſitical on the trunks of trees, in Jamaica and other Weſt Indian iſlands. The *leaves* proceed each from a large oval furrowed bulb, and are about a foot long. *Flower-ſtalks* radical, ſolitary, bearing a compound cluſter, three or four feet in length, and more or leſs pendulous. *Flowers* yellow, ſpotted with brown, their *calyx-leaves* and *petals* ſeſſile, more lanceolate and leſs undulated than in the former. *Lip* inverſely heart-ſhaped, convex, emarginate, not undulated.

3. G. *tetrapetalum.* Willd. n. 3. Swartz. Act. Holm. 240. (Epidendrum tetrapetalum; Jacq. Amer. 230. t. 142. Pict. 112. t. 216.)—Stem none. Leaves awl-ſhaped, keeled. Flowers in a ſimple cluſter. Calyx-leaves ovate, wavy. Lip ſtalked, kidney-ſhaped.—Native of woods in Jamaica. We know this ſpecies only from the publications of Jacquin, who repreſents the *flowers* as purpliſh, fragrant, without *petals* (as we call them); for he deſcribes the lip and three calyx-leaves as compoſing a flower of four petals. The *cluſter* is ſhort and ſimple, growing on a radical ſtalk about a foot high. *Leaves* ſeveral, three or four inches long, not half an inch wide.

4. O. *variegatum.* Willd. n. 4. Swartz. Ind. Occ. 1483. (Viſcum delphinii flore albo guttato minus, radice fibroſâ; Sloane Jam. v. 1. 251. t. 148. f. 2.)—Stem none. Leaves lanceolate, channelled, recurved, with cartilaginous ſerratures. Cluſter ſhort. Lip two-lobed. Paraſitical on trees in the mountainous parts of the Weſt Indies.—It has the habit of the laſt, and like that ſeems to want real *petals*. The *lip* and *calyx* are white, ſpotted with red, according to Swartz, who ſays the beautiful *flowers* appear in April.

5. O. *Ceboletta.* Willd. n. 5. Swartz. Act. Holm. 240. (Epidendrum Ceboletta; Jacq. Amer. 230. t. 131.

f. 2. Pict. 112. t. 217.)—Stem none. Leaves cylindrical awl-ſhaped, bulbous at the baſe. Cluſter compound, pendulous.—Native of woods, eſpecially near the ſea, at Carthagena. *Jacq.*—The *roots* creep on the branches of trees, bearing a crowd of little green bulbs, the ſize of hazel-nuts, each producing an erect *leaf*, not unlike that of a young onion, about a foot high. *Stalk* ſlender, much longer than the leaves, drooping, crowned by a ſhortiſh compound pendulous cluſter, which Jacquin ſaw in fruit only.

ONCINO, in *Geography*, a town of France, in the department of the Stura, on the Po; 14 miles W. of Saluzzo.

ONCOBA, in *Botany*, a genus of Forſkal's, ſo called from its Arabian name *Oncob.* Forſk. Ægypt-Arab. 103. Gmel. Syſt. Nat. v. 2. 828. Juſſ. 292. Lamarck Dict. v. 6. 210. Illuſtr. t. 471.—Claſs and order, *Polyandria Monogynia.* Nat. Ord. *Tiliaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, divided into four, deep, concave, obtuſe ſegments. *Cor.* Petals eleven or twelve, ſpreading, toothed; the outer ones longer than the calyx; the inner ſmaller, unequal. *Stam.* Filaments numerous, thread-ſhaped, erect, inſerted into the calyx; anthers erect, ſimple, linear. *Piſt.* Germen ſuperior, globoſe, longitudinally furrowed; ſtyle cylindrical, longer and thicker than the filaments; ſtigma orbicular, furrowed, ſeven-lobed. *Peric.* Berry globular, pulpy, of one cell, and many oblong, compreſſed *ſeeds*.

Eſſ. Ch. Calyx of one leaf. Petals numerous. Berry of one cell, many-ſeeded.

1. O. *ſpinoſa.* Gmel. Syſt. Nat. v. 2. 828.—Native of Egypt and Senegal, where it is called, according to Adanſon's herbarium, *Dimb*, or *Rimbot*. This is the only ſpecies known, being rather a lofty *tree*, with alternate, warty *branches*, each furniſhed with one or two *ſpines* about two inches long. *Leaves* alternate, ſhortly ſtalked, ovate, pointed, ſerrated, ſmooth. *Flowers* ſolitary, large, white. *Calyx* white internally. The *berries* are ſaid by Forſkal to be eaten by children.

ONCOS, ὄγκος, in *Antiquity*, was uſed to ſignify an ornament of the head, peculiar to thoſe who offered ſacrifice.

ONDA, in *Geography*. See *St.* Vincent *de la Pazes*.

ONDARROA, a town of Spain, in Biſcay; eight miles W. of St. Sebaſtian.

ONDATRA, in *Zoology*. See Mus *Zibethicus*.

ONDEE, in *Heraldry*. See Waved.

ONDEGGIARE, in the *Italian Muſic*, ſignifies to return the hand beating time, not directly, but by degrees; as *ondeggiare la mano*, to keep it waving in the air, or giving it two motions, before it is quite lifted up to end the bar, and thence to fall it to beat a firſt, ſecond, or third time, of that or another meaſure.

The Italians do not beat time merely by the two motions of *down* and *up*; but mark, by waving the hand, every portion of a bar. Suppoſe, for inſtance, a movement in common time of four crotchets in a bar, two accented and two unaccented: to the firſt accent the hand is beaten down; for the ſecond portion of the bar it is waved to the right; for the third to the left; and for the fourth and laſt part of a bar it is lifted up vertically, and comes down for the firſt note of the next bar, &c. In triple time of three portions, the hand comes down for the firſt, is waved to the right for the ſecond, and for the third lifted perpendicular.

ONDER Bokkeveld, in *Geography*, a territory of Southern Africa, being one of the tranſmontane diviſions of Stellenboſch near the Cape of Good Hope. This is the elevated flat ſurface of a table mountain, whoſe ſides on the W. and

W. and N. are high and almoſt perpendicular rocks, piled on each other in horizontal ſtrata like thoſe of Table mountain at the Cape, but it deſcends with a gentle ſlope to the eaſtward, and terminates in Karroo plains. The graſſes on the ſummit are ſhort but ſweet, and the ſmall ſhrubby plants are excellent food for ſheep and goats. The horſes are among the beſt which the colony produces, and the cattle thrive well. In ſome of the valleys, where the grounds admit of vegetation, the common returns of wheat are 40, and of barley 60, for one, without any reſt for 20 years, without fallowing, and without manure. The ſoil is deeply tinged with iron, and abounds with maſſes of iron-ſtone. Barrow's Travels in Southern Africa, vol. ii.

ONE-BERRY, in *Botany*. See *Herb* PARIS.

ONE-*Blade*. See SMILAX.

ONE-*Wheel Plough* See PLOUGH.

ONEEHEOW, in *Geography*, one of the Sandwich iſlands in the N. Pacific ocean, lying five leagues to the weſtward of Atooi, and not above fifteen leagues in circuit. The eaſtern coaſt is high and riſes abruptly from the ſea, but the reſt of the iſland conſiſts of low ground; excepting a round bluff head in the S.E. point, which terminates in a round hill. It produces abundance of yams, and of the ſweet root called "Tee." Here is ſalt, which the natives call "Patai," and is produced in ſalt ponds. With this they cure both fiſh and pork; and their ſalt fiſh kept very well, and was found to be very good. When captain Cook viſited this iſland in January 1778, ſix or ſeven canoes came off with ſome ſmall pigs and potatoes, and a good many yams and mats. The people reſembled thoſe of Atooi, and ſeemed to be equally acquainted with the uſe of iron, which they aſked for by the names of "Hamaite" and "Toe," parting readily with all their commodities for pieces of this precious metal. Many of them came readily on board, crouching down upon the deck, and not quitting this humble poſture till they were deſired to get up. The women, who were left in the canoes, behaved with much leſs modeſty than thoſe of Atooi, and at times all of them joined in a ſong, not remarkable for its melody, though performed in very exact concert, by beating time upon their breaſts with their hands. It appears certain, that the horrid banquet of human fleſh is as much reliſhed here, amidſt plenty, as it is in New Zealand. Some of the people, in anſwer to queſtions put to them on this ſubject, replied without heſitation, that if their navigators were killed on ſhore, they would certainly eat them. Their meaning plainly ſeemed to be, that they would not deſtroy them for the ſake of eating them, but that their eating of them would be the conſequence of previous enmity. One of the men had punctured on his breaſt the figure of a lizard, and upon thoſe of others were the figures of men badly imitated. This iſland had no chief or "hairee," but was ſubject to Teneoonao, a chief of Atooi. The ſoil of this iſland was found to be very poor and ſtony; but it was covered with ſhrubs and plants of more delicious fragrance than any which occurred in any other iſlands viſited in this ocean. There was no appearance of any running ſtream; but ſome ſmall wells were found, in which the freſh water, which was ſcarce, was tolerably good. The habitations of the natives were thinly ſcattered about; and it was ſuppoſed that there could not be more than 500 people upon the iſland. Their mode of living ſeemed to be decent and cleanly; but the men and women were not obſerved to eat together, and the latter ſeemed to aſſociate in companies by themſelves. It was found that they burnt here the oily nuts of the "dooe dooe" for light in the night, as at Otaheite; and that they baked their hogs in ovens; but, contrary to the practice of the Society and Friendly iſlands, they ſplit the carcaſes through their whole length. The "taboo," or as they called it, "tapoo," was found to exiſt in this iſland, for one woman fed another who was under that interdiction. They alſo obſerved ſome other myſterious ceremonies. A particular veneration ſeemed to be paid here to owls, which are very tame; and it was obſerved to be a pretty general practice among them to pull out one of their teeth, in which they agreed with Dampier's natives on the W. ſide of New Holland, although at ſuch an immenſe diſtance; for this practice the only reaſon they aſſigned was, that it was "teeha," which is the reaſon given for another of their practices, the giving a lock of their hair. Cook's Third Voyage, vols. ii. iii. N lat. 21° 50'. E. long. 199° 45'.

ONEG, a town of Ruſſia, in the government of Archangel, on the river Onega, near the White ſea; 80 miles S.S.W. of Archangel. N. lat. 63° 35'. E. long. 37° 24'.

ONEGA, a river of Ruſſia, which riſes in the N.W. part of the government of Vologda, and runs into the White ſea.—Alſo, a lake of Ruſſia, in the government of Olonetz, between the Ladoga and the White ſea. The length is between 180 and 200 verſts, and its breadth from 60 to 80. Like the Ladoga it contains a few iſlands conſiſting of marble, and in all other properties is much the ſame. As from the Onega the navigable river Svir runs into the Ladoga, and from the Bielo-Ozero the Shakſna flows into the Volga, a canal cut through the diſtance of 40 verſts would connect the Neva with the Volga, and afford a more convenient navigation than the paſſage by Viſhnoi-Volotſhok, becauſe there are no water-falls, and therefore all the danger and trouble attending them in the preſent paſſage would be obviated. Tooke's Ruſſ. vol. i.

ONEGLIA, or ONEILLA, a ſea-port and capital of a principality, on the coaſt of the Mediterranean, which carries on a conſiderable trade in olive-oil. It is well built, and had formerly a large and good citadel, which has been deſtroyed. In October 1792 the French attacked it both by land and ſea, and having taken it by ſtorm, ſurrendered it to a general plunder, and afterwards ſet fire to it in ſeveral places; 30 miles N.E. of Nice. N. lat 43° 55'. E. long. 8° 4'.—Alſo, a principality ſurrounded on all ſides, except towards the ſea, by the territory of the Genoeſe. It conſiſts of three vallies, *viz.* Oneglia, Maro, and Prela. The firſt is covered with fruit-trees, intermixed with houſes, ſo as to have the appearance of a continued orchard. Maro, or Mairo, extends from the village of St. Lazara to the col of St. Bernard, where it joins the valley of Piéva, in the juriſdiction of the Genoeſe. The third valley of Pierrelata, or Prela, lies to the W. of the other two. All theſe vallies extend 19 miles from the ſea, and in them are reckoned 53 towns or villages, 3000 families, 14,000 inhabitants, and 2000 men fit to bear arms. The country produces wines, fruits, and excellent olive-oil. The capital is Oneglia.

ONEIDA, a county of New York, bounded N.E. and E. by Herkemer county, S.E. by Otſego county, S. by Oneida lake and Chenango, and W. by lake Ontario. This county, 90 miles from N. to S. and from 40 to 60 from E. to W., is well watered and the ſoil is fertile. The number of inhabitants is 22,047.

ONEIDA *Creek*, a river of New York, which runs into lake Oneida. N. lat. 49° 3'. W. long. 75° 47'.

ONEIDA *Lake*, a lake of America, in the ſtate of New York, between 20 and 30 miles long, and five miles wide; it is connected with lake Ontario on the W. by Oſwego river, and with fort Stanwix by Wood creek.

ONEIDAS, one of the SIX NATIONS of Indians, containing 628 perſons, who inhabit the country S. of Oneida lake, called the Oneida Reſervation. Their principal village,

Kahaomerolakala is about 20 miles S.W. of Whiteſtown. This nation receives an annuity from the ſtate of New York of 3552 dollars for lands purchaſed of them in 1795, and an annuity of about 628 dollars from the United States. Theſe annuities, together with the corn, beans, and potatoes, raiſed by the ſquaws, and the fiſh and game caught by the men, afford them a barely tolerable ſubſiſtence. Their pride leads them to deſpiſe their neighbours, the Stockbridge and Brotherton Indians, for their attention to agriculture; but being under a neceſſity of purchaſing proviſions of them, they begin to feel a ſenſe of their dependence. They are divided into three tribes, or clans, by the names of the Wolf, the Bear, and the Turtle. They have their name from their Pagan deity, which ſome few of the natives ſtill worſhip, notwithſtanding the inſtruction of miſſionaries from the ſociety eſtabliſhed in Scotland for promoting Chriſtian knowledge; which deity is merely a mis-ſhapen, rude, cylindrical *ſtone*, about 120 pounds in weight, in their language called "Oneida," ſignifying the "Upright Stone." Formerly this ſtone was placed in the crutch of a tree, and then the nation ſuppoſed itſelf invincible. Theſe Indians are all of mixed blood; inſomuch, that there has not been a *pure* Oneida for ſeveral years paſt.

ONEIROCRITICA, ονειροκριτικη, the art of interpreting dreams, or a method of foretelling future events, by means of dreams.

The word is formed from the Greek, ονειρος, *dream*, and κριτικη, of κρισις, *judgment*. Some call it *oneirocratia*, and derive it from ονειρος, and κρατεω, *I poſſeſs*, *I command*. It appears from ſeveral paſſages of ſcripture, that there was, under the Jewiſh diſpenſation, ſuch a thing as foretelling future events by dreams; but then there was a particular gift, or revelation, required for that purpoſe.

It ſhould ſeem, hence, that dreams are really ſignificative, and do forebode ſomething to come; and all that is wanting among us is the oneirocritica, or the art of knowing what: yet it is the opinion of many, that dreams are mere chimeras; bearing, indeed, ſome relation to what has paſſed, but none to what is to come. As to the caſe of Joſeph, it was poſſible for God, who knew all things, to diſcover to him what was in the womb of fate; and, to introduce that, he might take the occaſion of a dream; not but that he might as well have foretold it from any other accident or circumſtance whatever: unleſs God, to give the matter more weight, ſhould purpoſely communicate ſuch a dream to Pharoah, in order to fall in with the popular notion of dreams and divination, which then prevailed among the Egyptians. See DREAM.

ONEIROCRITICS, formed from ονειρος, *dream*, and κρισις, *judgment*, a title given to interpreters of dreams, or thoſe who judge of events from the circumſtances of dreams.

There is no great regard to be had to thoſe Greek books called oneirocritics; nor do we, indeed, know why the patriarch of Conſtantinople, and others, ſhould amuſe themſelves with writing on ſo mean a ſubject.

Rigault has given us a collection of the Greek and Latin works of this kind; one attributed to Aſtrampſichus; another to Nicephorus, patriarch of Conſtantinople; to which are added, the treatiſes of Artimedorus and Achmet. But the books themſelves are little leſs but reveries; a kind of waking dreams, to explain and account for ſleeping ones.

The ſecret of oneirocriticiſm, according to them all, conſiſts in the relation ſuppoſed to be between the dream and the thing ſignified; but they are far from keeping to the relations of agreement and ſimilitude; and frequently they have recourſe to others, of diſſimilitude and contrariety.

ONEIROPOLI, ονειροπολοι, or *Oneiroſcopi*, in *Antiquity*, perſons whoſe buſineſs it was to make predictions from dreams.

ONEMACK POINT, in *Geography*, the S.W. point of the continent of North America, on the N.W. coaſt, and the S. limit of Briſtol bay; 82 leagues S.S.W. of cape Newenham, on the N. point of that extenſive bay. N. lat. 54° 30'. W. long. 163° 30'.

ONEMENSKAIA, a lake of Ruſſia, in the river Anadyr; 208 miles below Anadyrſkoi, communicating with the gulf of Anadyr.

ONERANDO *Pro Rata Portionis*, in *Law*, a writ which lies for a joint-tenant, or tenant in common, when diſtrained for more rent than the proportion of his land comes to.

ONESON, in *Geography*, a town of Nubia, on the left bank of the Nile; 30 miles N.E. of Sennaar.

ONEVI, one of the ſmaller Friendly iſlands, in the South Pacific ocean, near the N. coaſt of Tongataboo; 5 miles N.E. of Obſervatory Point.

ONEZSKOE, a lake of Ruſſia, in the government of Olonetz; 120 miles long, and about 40 at its medial breadth; containing ſeveral iſlands. N. lat. 61° to 67°. E. long. 29° to 31°.

ONFZANI, a town of European Turkey, in Moldavia; 31 miles N.N.E. of Saſſi.

ONGAR, or CHIPPING-ONGAR, a market-town and pariſh in the hundred of Ongar, and county of Eſſex, England, is ſituated at the diſtance of 10 miles W. by S. from Chelmsford, and 21 miles N.E. from London. The town is ſuppoſed to be of great antiquity, and to have been of conſiderable importance, firſt under the Romans, and ſubſequently under the Saxons and Normans. After the conqueſt, a ſtrong caſtle was erected here by Richard de Lucy, who was chief juſtice of England in the reign of Henry II. A high mount, called the Keep, and ſome other remains of this fortreſs, are ſtill viſible on the eaſt ſide of the town; and from their extent and magnitude would induce the belief of the caſtle having been formed out of a fortification of ſtill greater antiquity and dimenſions. A wide and deep moat, commonly filled with water, ſurrounds the keep. A ſteep winding walk, now ſhaded with a thick plantation of trees and ſhrubs, leads to the ſummit.

Chipping-Ongar is now only a trifling place, and conſiſts of one long and wide ſtreet. The church, a ſmall ſtructure, is remarkable for the caſtellated loop-hole appearance of its windows. Within the church is a monument in honour of Jane, daughter of lord Oliver Cromwell of Hinchinbrooke, in Huntingdonſhire. The market-day in this town is Saturday weekly, and there are two fairs every year. According to the parliamentary returns of 1811, the whole pariſh contained 120 houſes, and 678 inhabitants.

About a mile from Ongar ſtands the village of Greenſted, which particularly deſerves notice on account of its church. This is regarded by antiquaries as one of the moſt ancient and curious ſpecimens of architecture in our iſland. The nave is entirely compoſed of the trunks of oak trees, ſplit or ſawn aſunder, and fixed upright in a ſill and plate, cloſe to each other. "On the ſouth ſide are ſixteen, and two door-poſts; on the north twenty-one, and two vacancies, filled up with plaſter. The weſt end is built againſt by a boarded tower; and the eaſt by a chancel of brick; on the ſouth ſide is a wooden porch, and both ſides are ſtrengthened by thick buttreſſes: the roof is of later date, and tiled." The total length of the wooden portion of the church is twenty-nine feet nine inches; the width fourteen feet; and the height, to the ſpring of the roof, five feet ſix inches.

According

According to tradition, this edifice was erected as a temporary ſhrine for the corpſe of one of our ancient kings; and Smart Lethieullier, eſq. ſtates that the body of St. Edmund, when on the way to its place of ſepulture at St. Edmund's Bury, was "entertained at Aungre (Ongar), where a wooden chapel erected to his memory remains to this day." Contiguous to the church is the ſeat of Craven Ord, eſq. one of the maſters in chancery.

At Fyfield, a mile north-eaſt from Ongar, a variety of Celts were diſcovered in 1749: and near Naveſtock, a ſeat of the earl of Waldegrave, is an ancient monument, ſuppoſed by Stukeley to be a Druid temple of the kind which he called Alate.

Otes, four miles to the north of this town, was the ſeat of the lords Maſhams, and diſtinguiſhed as the retreat of the celebrated John Locke, who died here in 1704, and lies buried under a plain altar in the village church-yard, having an inſcription upon it from his own pen. Camden's Britannia by Gough, vol. ii. folio. Beauties of England and Wales, vol. v. by E. W. Brayley, and John Britton, F. S. A.

ONGERCURRY, a town of Hindooſtan, in the province of Cattack; 22 miles E. of Guntoor.

ONG-KIN, a town of Corea; 58 miles S.W. of Hoang.

ONG-LAKE, a river of Madagaſcar, which runs into the bay of St. Auguſtine.

ONGLEE, or ONGLE, is uſed by the French heralds to denote the talons or claws of beaſts or birds, when of colours different from the body.

ONGLET, in *Ornithology*. See TANAGRA *Striata*.

ONGOA, in *Geography*, a town of Africa, in the country of Mocaranga; 80 miles N.W. of Maſſapa.

ONGOBOLU, one of the ſmaller Friendly iſlands; 6 miles E. of Neneeva.

ONGOLE, a circar of Hindooſtan, in the Carnatic, E. of Cuddapa, and S. of Guntoor.—Alſo, the capital of the above circar, ſituated in the northern part of the Carnatic; 65 miles N. of Nellore. N. lat. 15° 30′. E. long. 78° 58′.

ONGO-MANCAN, a town of Chineſe Tartary. N. lat. 43° 32′. E. long. 121° 22′.

ONI, a town of Imiretta; 65 miles N.E. of Cotatis.

ONIDA, a ſmall iſland in the gulf of Venice. S. lat. 44° 42′. E. long. 14° 47′.

O-NIMAMOU, a harbour on the S.E. coaſt of the iſland of Ulietea; N.E. of Ohetuna, a harbour on the ſame coaſt.

ONION, CAPE, a cape on the S.W. ſide of Newfoundland iſland, about four leagues W. of Quirpon iſland, or the northern point of that extenſive iſland.

ONION *River*, a river of America, in the ſtate of Vermont, formerly called "French River," and by the Indians "Winooſki," which riſes in Cabot, about 14 miles W. of Connecticut river, and is navigable for ſmall veſſels five miles from its mouth, in lake Champlain, between the towns of Burlington and Colcheſter, and for boats between its ſeveral falls. This is ſaid to be one of the fineſt ſtreams in Vermont; and it runs through a very fertile country, the produce of which, for ſome miles on each ſide of the river, is brought down to the lake at Burlington. It is from 20 to 30 rods wide, to the lower falls, and 15 or 20 rods, 40 miles from its mouth, and its deſcent in this interval is 172 feet, or about four feet *per* mile. Between Burlington and Colcheſter it has forced a paſſage through a ſolid rock of lime-ſtone, which at ſome remote period muſt have formed at this place a prodigious cataract. The chaſm is between 70 and 80 feet in depth at low water, and in one place 70 feet from rock to rock, where it is traverſed by a wooden bridge. At Bolton there is a chaſm of the ſame kind, and the rock is at leaſt 130 feet high. From one ſide ſeveral rocks have fallen acroſs the river, ſo as to form a natural bridge at low water, but in a ſituation that renders it merely an object of curioſity. The Indians formerly paſſed along this river from Canada, when they made their attacks on the frontier ſettlements, on Connecticut river. Morſe.

ONJONG-MASSANG, a town on the W. coaſt of Sumatra, on the Line. E. long. 99° 21′.

ONIONS, in *Botany*, *Gardening*, *Dietetics*, and the *Materia Medica*. See ALLIUM.

ONIONS, *Sea*. See SQUILL.

ONION-*Shell*, in *Natural Hiſtory*, a name given by authors to a peculiar kind of oyſter, which is of a roundiſh figure and very thin and tranſparent, and repreſents very exactly a piece of the peel of an onion. See OSTREA.

ONIS, in *Geography*, a town of Spain, in Aſturias, ſituated E. of Cangas de Onis, at the foot of a mountain, and upon the little river Curado.

ONIS, *Cangas de*, a town of Spain, in Aſturias, ſituated at the confluence of two rivers, one of which, the Sella, is croſſed by a beautiful bridge of one arch. This town has the freedom of a municipal adminiſtration. This and the laſt-mentioned town lie in the road from Oviedo to Santa Cruz.

ONISCUS, in *Ichthyology*, a name given by Athenæus, and others of the Greek writers, to the acipenſer, or ſturgeon.

ONISCUS is alſo the officinal name of the whiting. See GADUS *Merlangus*.

ONISCUS, in *Entomology*, a genus of inſects of the order Aptera; of which the generic character is: Jaw truncate, denticulate; lip bifid; the antennæ are ſetaceous, and are from two to four in number; the body is oval, conſiſting of about fourteen tranſverſe ſegments; and it has fourteen legs. There are forty-three ſpecies, ſeparated into two ſections. They all feed on animal and vegetable matter, and caſt their ſkin. The ſea oniſci are larger than thoſe of the freſh water, having ten inſtead of ſeven ſegments. Their motions in the water are rapid, for beſides the feet, they are aſſiſted by lateral threads, which puſh them forward like the oars of a boat. Among them, the act of copulation is ſaid to laſt ſeveral days; when the male ſeizes his female with his two fore-feet, and drags her along with him wherever he directs his courſe. On the ſeventh day after impregnation the young iſſue from the mother alive, and ſwim about with vigour and alertneſs. The ſea oniſci are ſuppoſed to be viviparous; thoſe of the land oviparous: the former are of a pale red colour for ſome time after being excluded from the ſhell.

Diviſion A. Theſe have no feelers; they have frequently four antennæ, that are ſeſſile. This diviſion compriſes the Cymothoa of Fabricius, and contains thirty-eight ſpecies, of which ten, as will be marked in the deſcription, are common to our own country.

Species.

PARADOXUS. This ſpecies has the ſegments of the body falcate and ſpinous. It is found in Terra del Fuego, and is a large inſect.

IMBRICATUS. Antennæ compreſſed; legs furniſhed with claws; hind-thighs carinate. It inhabits New Zealand: it is large, oblong, and pale.

FALCATUS. The ſegments of the body of this are fal-

cate and two-ſpined at the ſides. It inhabits the Chineſe ocean.

* ASILUS. Abdomen covered with two ſcales; the tail is ſemi-oval. It inhabits the European ocean.

GAUDALOUPENSIS. The abdomen of this inſect is covered with ſix ſcales; the tail is ovate, entire. It inhabits the American ocean.

* OESTRUM. Abdomen covered with ſix ſcales; the tail retuſe. It is found in European ſeas.

* ENTOMON. Abdomen naked beneath; tail oblong, acute. It inhabits the European ocean, and preys on ſmall fiſh.

* AQUATICUS. The tail is rounded, with forked ſtyles; it has four antennæ. This is found in ſtagnant waters in many parts of Europe. The young are contained in a ſix-cleft follicle.

* MARINUS. Semi-cylindrical; tail oval-oblong, pointed. It inhabits the European ſeas.

* LINEARIS. Body linear; tail four-toothed. It inhabits the European and Indian ſeas.

CHELIPES. Oblong; tail three-toothed; legs ſlightly chelate. It is found in the Atlantic among ſea-weed.

BICAUDATUS. Semi-cylindrical, with two tails as long as the body. It inhabits the ſeas of Norway.

SCOPULORUM. Body pale yellow with brown ſtreaks. Inhabits the ſeas of Norway.

AMERICANUS. Abdomen covered with twelve ſcales; hind-legs long and rufous; tail rounded. It inhabits the American ocean.

PSORA. Abdomen naked beneath; tail ſemi-oval, acute. It inhabits Norway.

* PHYSODES. Abdomen naked beneath; tail ovate. It inhabits Europe.

* BIDENTATUS. Abdomen naked; tail very obtuſe, the laſt ſcale two-toothed. In this the body is very minute, and marked on the upper ſide with ſix tranſverſe rows of ochreous ſpots; the ſcales are even, the laſt with two teeth.

SPINOSUS. Body oblong, ſpinous and pellucid. It is found in the Atlantic ocean; the body is gelatinous.

ACUMINATUS. Oblong, grey; antennæ and legs paler; tail pointed. It inhabits the ocean.

EMARGINATUS. This is oblong and of a grey-brown; the tail is emarginate. It inhabits the ocean.

ALBICORNIS. Oblong, brown; tail pale, dotted with black. It inhabits the Spaniſh ſeas.

CETI. Ovate, with diſtinct ſegments; third and fourth pair of legs linear and unarmed. It inhabits the northern ſeas, and infeſts the whale; hence its ſpecific name.

* OCEANICUS. Ovate; tail ending in two bifid ſtyles. It inhabits the European ocean.

SERRATUS. Ovate, brown; tail with five plates; the outer ones ſerrate without. It inhabits the Spaniſh coaſt, and is ſmall.

* ASSIMILIS. Ovate; tail obtuſe, unarmed; body cinereous. It inhabits Europe.

CORALLINUS. Lanceolate; above brown; tail oblong-triangular, and crenate.

ACULEATUS. The thorax is naked; the back is beſet with three rows of ſpines. It is found in the White ſea.

SCORPIOIDES. Thorax oval-globular; tail long, jointed, ending in a ſpine and bifid briſtles. This alſo is an inhabitant of the White ſea; as is the next.

CUSPIDATUS. Thorax articulate, tuberculate; the ſix dorſal ſegments cuſpidate.

HECTICUS. Cinereous, linear; tail linear, bicuſpidate, with two linear ſtyles. It is an inhabitant of the Atlantic.

TINEA. Ovate; green ſpotted with black; the tail is rounded. It inhabits Denmark.

TRIDENTATUS. This is flattiſh; the tail is compoſed of two plates, and is three-toothed. It inhabits Denmark.

FUSCUS. This is of a brown colour; the ſhell is carinate with a white ſpot on the thorax. It is alſo found in Denmark.

CICADA. A little compreſſed, ſublinear, with four ſpurious bands; the upper antennæ ſhorter; tail ſmooth on the back. It inhabits the Greenland ſeas.

MEDUSARUM. Compreſſed; front obtuſe; antennæ very ſhort and pendent; four hands compreſſed and cut. It is found under the folds of the Meduſa capillata.

ARENARIUS. This is ſlightly depreſſed before, carinate and ſubſerrate behind; it has four fore-legs cheliform and ſmooth; the antennæ are nearly equal.

STRŒMIANUS. Compreſſed; four fore-legs cheliform and ſlightly toothed; the upper antennæ very ſhort. It inhabits the ſhores of Greenland: the body is of a violet colour.

ABYSSINUS. Sub-cylindrical; it has four fore-legs cheliform and one-toothed; the antennæ are ſubequal, ſetiferous and ſerrate at the baſe on the inner margin. It inhabits Greenland: the body is marked with white and ſaffron bands: it darts with great velocity in the water.

Diviſion B contains five ſpecies, of which two are common to our own country. They have unequal feelers, the hind ones longer; antennæ filiform.

MACULATUS. Tail obtuſe and unarmed; the body is of a lead colour, with dotted white lines. It is found in Italy, and is twice the ſize of the armadillo to be deſcribed preſently; the body is marked with ſeven longitudinal white dotted lines.

PUSTULATUS. Black; with four red dots on the firſt ſegment, and two whitiſh ones on the reſt. It inhabits ſouthern Europe.

* ASSELLUS; the Wood-louſe. Tail obtuſe, with two ſimple ſtyles. It is rather more than half an inch long; the colour is of a livid brown. It inhabits Europe in walls, rotten wood, and under ſtones; it preys on minuter inſects; it infeſts England and many other parts of Europe. The young are contained in a four-valved follicle under the abdomen of the mother.

SYLVESTRIS. Tail with four ſtyles, the lateral ones longer. It inhabits France, and is leſs than the laſt.

* ARMADILLO; Millepede, or Medical Wood-louſe. The body of this inſect is of a grey-brown; the tail is obtuſe and entire; the body conſiſts of ten ſegments, the edges of which are white; it is longer than the aſſellus, of a darker colour, and a more poliſhed ſurface; but found in ſimilar ſituations: when ſuddenly diſturbed or handled it rolls itſelf up into a completely globular form, in the manner of the armadillo, hence its ſpecific name. See MILLEPEDES.

ONISION, in *Geography*, a town of Perſia, in the province of Irak; 20 miles N. of Conſar.

ONKELOS, in *Biography*, a celebrated rabbi, who flouriſhed in the firſt century, and was author of the Chaldee TARGUM, (which ſee,) or tranſlation of the Pentateuch, which is called after his name. He was probably a contemporary with Jonathan Ben Uzziel, author of the Targum of the prophets, but by much the younger of the two. For according to the Jewiſh writers Jonathan was one of the principal ſcholars of Hillel, who died about the time of our Saviour's birth; while Onkelos ſurvived Gamaliel,

liel, the maſter of St. Paul, who was grandſon of Hillel, and who lived till within eighteen years of the deſtruction of Jeruſalem. It is ſaid that Onkelos aſſiſted at the funeral of Gamaliel, and contributed largely to the expence of it. Our own hiſtorian, Prideaux, is of opinion, that Onkelos was of older ſtanding than Jonathan, alleging, as one of the principal reaſons for adopting it, the purity of ſtyle in which his Targum is written; for the nature of this argument we again refer to the article TARGUM. The firſt Latin verſion of this work was made by Alphonſus de Zamora, and publiſhed in the Complutenſian edition of the Polyglot, in 1517, whence it was adopted into the Antwerp in 1572; into that of Le Jay at Paris, and alſo into our countryman Walton's, in 1657.

ONKOTOMY, formed from ὀγκος, *tumour*, and τεμνω, *I cut*, in *Surgery*, the operation of opening a tumour or abſceſs.

ONNA, in *Geography*, a town of Thibet; 15 miles N.N.W. of Morou Conghé.

ONOBA, or ONUBA, now *Moguer*, a town of Spain, in Bœtica, towards the S.W. at the bottom of a ſmall bay. Pliny places it at the confluence of the Luxia and the Unrium, and gives it the ſurname of "Æſtuarium," indicating its being ſituated on the ſea-coaſt, and thus diſtinguiſhing it from another *Onoba*, in the interior of the country, belonging to the Turduli.

ONOBRYCHIS, in *Botany*, is Tournefort's ſynonym for HEDYSARUM, ſee that article.

ONOCENTAURUS, a fabulous animal, ſuppoſed to be a compound of a man and an aſs. Ælian ſpeaks of onocentaurs. It was half man and half aſs, as the centaur was half man and half horſe. Lib. vii. cap. 9.

ONOCHORUS, in *Ancient Geography*, the name of one of the five principal rivers of Theſſaly, according to Herodotus and Pliny.

ONOCLEA, in *Botany*, was ſo called by Linnæus, from ονος, *a ſort of veſſel*, and κλειω, *to ſhut up*. He appears to have taken the idea from Mitchell, who gave the name of *Angiopteris* to this fern; which being compoſed of αγγειον, *a veſſel*, and πτερις, *a fern*, was juſtly, according to his rules, inadmiſſible, ſince another eſtabliſhed genus was called *Pteris*. Both appellations allude to the apparent capſules, ranged in a two-ranked ſpike, but which are, in fact, formed of the cloſely inflexed lobes of the frond, concealing the real ſeed-veſſels.—Linn. Gen. 559. Schreb. 756. Willd. Sp. Pl. v. 5. 287. Mart. Mill. Dict. v. 3. Juſſ. 15. Lamarck Illuſtr. t. 864. (Struthiopteris; Willd. Sp. Pl. v. 5. 288.) —Claſs and order, *Cryptogamia Filices*. Nat. Ord. *Filices dorſiferæ annulatæ*.

Eſſ. Ch. Capſules covering the back of the frond. Involucrum from the cloſely reflexed marginal ſegments of the leaf.

Obſ. At the ſuggeſtion of Mr. Brown in his Prodr. Nov. Holl. v. 1. 152, under *Stegania*, perfectly in uniſon with our own judgment, we combine the *Struthiopteris* of Willdenow with *Onoclea*, while we conſider every thing elſe, that has been at any time referred to this genus, except our third ſpecies, as foreign to it. (See GLEICHENIA.) Moſt of the *Onocleæ* of Swartz make a principal part of a new genus of Willdenow, *Lomaria*, Sp. Pl. v. 5. 289, and among them *Acroſtichum ſpicatum*, Linn. Suppl. 444. Sm. Ic. ex Herb. Linn. t. 49. In *Lomaria* the involucrum is uninterrupted, proceeding in like manner from the inflexed edge of the leaf, and covering the continuous maſs of capſules.

1. O. *ſenſibilis*. Linn. Sp. Pl. 1517. Swartz. Fil. 110. Michaux Boreal-Amer. v. 2. 272. (Filix mariana, oſmundæ facie racemifera; Pluk. Mant. 80. t. 404. f. 2. Polypodium virginianum, oſmundæ facie; Moriſ. ſect. 14. t. 2. f. 10.) —Barren fronds pinnate; leaflets decurrent, ſinuated; the upper ones confluent. Native of various parts of North America, in moiſt ſhady places. It has long been known in the more curious gardens of England. The *root*, of courſe, is perennial. *Fronds* ſeveral, about a foot and a half, or two feet, high, with long ſmooth ſtalks; the barren ones compoſed of ſeveral oblong leaflets, more or leſs deeply waved or ſinuated, the uppermoſt confluent, and all ſomewhat decurrent, ſmooth and of a thin texture, ſo delicate that, as we have heard, the frond ſoon fades after being drawn through the hand while growing; which Moriſon alſo relates on the authority of Simon Paulli. The fertile *fronds* have a totally different appearance, each leaflet reſembling a crowded ſpike of capſules, which it was actually taken to be by Mitchell, Linnæus, and the writer of this in the Memoirs of the Academy of Turin, v. 5. Now each ſuppoſed capſule is found to be a cloſely reflexed lobed leaflet, whoſe concealed under ſide is covered with innumerable minute bivalve *capſules*, each bound with an elaſtic ring, as in other ferns.

2. O. *Struthiopteris*. Swartz. Filic. 111. (Oſmunda Struthiopteris; Linn. Sp. Pl. 1522. Fl. Dan. t. 169. Gunn. Norveg. 1. t. 1. f. 1—3. Struthiopteris germanica; Willd. Sp. Pl. v. 5. 288.)—Barren fronds pinnate; leaflets ſeſſile, pinnatifid; their ſegments rather acute, regular in length.—Native of bogs in the moſt northern regions of Europe, as well as in ſome parts of Germany and Switzerland. This is a noble fern, three or four feet high, the barren *fronds* not much unlike *Aſpidium Filix mas* in general appearance, but larger, and ſcarcely crenate; the fertile ones more central and erect, with longer ſtalks, and compoſed of ſhorter leaflets, having the ſame beaded or jointed appearance as the former, from which we do not ſee how this plant can be generically divided. It is well worthy of a place in the bog bed of every curious garden.

3. O. *penſylvanica*. (Struthiopteris penſylvanica; Willd. Sp. Pl. v. 5. 289.)—Barren fronds pinnate; leaflets pinnatifid; their ſegments obtuſe; the lowermoſt elongated and acute.—Native of Penſylvania, from whence it was ſent by Dr. Muhlenberg to profeſſor Willdenow, who ſays it is very like the laſt, but different in the ſpecific characters above given.

ONOCROTALUS, in *Ornithology*, a ſpecies of *Pelecanus*; which ſee.

ONOFRIO, ST., the name of one of the famous conſervatorios at Naples. The boys of this conſervatorio wear a white uniform. We heard them perform in the church of Santa Maria di Loreto. The performance, in general, was coarſe and clumſy; genius and fire were diſcoverable now and then in the compoſitions of theſe ſtudents; but all was unfiniſhed. Theſe ſeminaries, which heretofore produced ſuch great profeſſors, ſeem at preſent to be but low in genius. However, ſince theſe inſtitutions, as well as others, are ſubject to fluctuations, after being languid for ſome time, like their neighbour Mount Veſuvius, they will, perhaps, blaze out again with new vigour.

We went a ſecond time to hear the boys of St. Onofrio, at the Franciſcans' church. They performed a Litany, that was compoſed by Durante; the reſt of the muſic, which ſeemed to be that of a raw and inexperienced compoſer, was by a young man, who beat time. There was again a ſolo on the inſtrument called "La Voce Humana;" it is of an agreeable tone, has a great compaſs, but was not well played

on. A concerto on the violin was likewiſe introduced, where hand and fire were diſcovered by the player, but no taſte or feeling.

We were admitted into the interior of the conſervatorio of St. Onofrio the next day, and viſited all the rooms where the ſtudents practiſe, eat, and ſleep. On the firſt flight of ſtairs was a trumpeter, ſcreaming upon his inſtrument till he was ready to burſt; on the ſecond was a French horn, bellowing in the ſame manner. In the common practiſing room there was a Dutch concert, conſiſting of ſeven or eight harpſichords, more than as many violins, and ſeveral voices, all performing different things, and in different keys: other boys were writing in the ſame room; but it being holiday time, many were abſent who uſually ſtudied and practiſed in this room. The jumbling them all together in this manner may be convenient for the houſe, and may teach the boys to attend to their own parts with firmneſs, whatever elſe may be going forward at the ſame time; it may likewiſe give them force, by obliging them to play loud in order to hear themſelves; but in the midſt of ſuch jargon, and continued diſſonance, it is wholly impoſſible to give any kind of poliſh or finiſhing to their performance; hence the ſlovenly coarſeneſs ſo remarkable in their public exhibitions; and the total want of taſte, neatneſs, and expreſſion in all theſe young muſicians, till they have acquired them elſewhere.

The beds, which are in the ſame room, ſerve for ſeats to the harpſichords and other inſtruments. Out of thirty or forty boys who were practiſing, we could diſcover but two who were playing the ſame piece. The violoncellos practiſe in another room; and the flutes, hautbois, and other wind inſtruments, in a third, except the trumpets and horns, which are obliged to fag, either on the ſtairs, or on the top of the houſe.

The only vacation in theſe ſchools, in the whole year, is in autumn, and that for a few days only: during the winter, the boys riſe two hours before it is light, from which time they continue their exerciſe, a hour and a half at dinner excepted, till eight o'clock at night; and this conſtant perſeverance, for a number of years, with genius and good teaching, muſt produce great muſicians.

ONOMANCY, or rather ONOMAMANCY, the art of divining the good or evil fortune which ſhall befall a man, from the letters of his name.

The word is ſuppoſed to be formed from the Greek ονομα, *name*, and μαντεια, *divination*. Indeed, there is ſomething ſingular in the etymology; for in ſtrictneſs, onomancy ſhould rather ſignify divination by aſſes; being formed from ονος, *aſinus*, and μαντεια: to ſignify divination by names, it ſhould be *onomatomancy*.

Onomantia was a very popular and reputable practice among the ancients. The Pythagoreans taught, that the minds, actions, and ſucceſſes of men, were according to their fate, genius, and name; and Plato himſelf ſeems ſomewhat inclinable to the ſame opinion.

One of the greateſt rules of onomancy, among the Pythagoreans, was, that an even number of vowels in a name ſignified an imperfection in the left ſide of a man; and an odd number in the right. Another rule, about as good as this, was, that thoſe perſons were the moſt happy, in whoſe names, the numeral letters, added together, made the greateſt ſum; for which reaſon, ſay they, it was, that Achilles vanquiſhed Hector; the numeral letters in the former name amounting to a greater number than the latter.

And it was, doubtleſs, from a principle much of the ſame kind, that the young Romans toaſted their miſtreſſes at their meetings as often as there were letters in their names. Thus Martial,

"Nævia ſex cyathis, ſeptem Juſtina bibatur."

ONOMATOPŒIA, formed from ονομα, *name*, and ποιεω, *fingo*, *I feign*, in *Grammar* and *Rhetoric*, a figure of ſpeech, whereby names and words are formed to the reſemblance of the ſound made by the thing ſignified.

Thus in the word *trique-trac*, formed from the noiſe made by moving the men at this game: and from the ſame ſource ariſe the *hux* of bees, the *grunting* of hogs, the *cackling* of hens, the *ſnoring* of people aſleep, the *claſhing* of arms, &c.

The ſureſt etymologies are thoſe deduced from the onomatopœia.

ONONDAGO, or SALT *Lake*, in *Geography*, a lake of America, in New York, about ſix miles long and one broad, which diſcharges its waters to Seneca river. It derives its ſaltneſs from ſaline ſprings, a few miles from its banks, and furniſhes immenſe quantities of ſalt to the great benefit of the country.

ONONDAGO, a river of New York, which riſes in the Oneida lake, and runs weſtward into lake Ontario at Oſwego. It is paſſable by boats from its mouth to the head of the lake, 74 miles, except the interval of a fall which is 20 yards; and thence batteaux go up Wood creek almoſt to Fort Stanwix, 40 miles, whence there is a portage of a mile to Mohawk river. Towards the head of this river there is plenty of ſalmon.—Alſo, a county of New York, conſiſting of military lands, divided into nine townſhips: this county is bounded W. by Ontario county and N. by lake Ontario, the Onondago river and Oneida lake. The county courts are held in the village of Aurora, in the townſhip of Scipio. Onondago county is well adapted to inland navigation, on account of its two navigable rivers, Seneca and Oſwego, its five lakes and a number of creeks. The inhabitants are 7406.—Alſo, a poſt-town, and formerly the chief town of the Six Nations, ſituated in a pleaſant and fertile part of the country, on the S. end of the lake of the ſame name, and conſiſted of five ſmall towns or villages.

ONONDAGOES, a tribe of Indians, who live near Onondago lake. Between 20 or 30 years ago they could furniſh 260 warriors. This nation, now conſiſting of 450 perſons, receives annually from the ſtate of New York 2000 dollars, and from the United States about 450 dollars. N. lat. 42° 58′. W. long 75° 40′.

ONONGHOUAGO, a town of America, in New York, ſeated on the Suſquehanna; 13 miles E. of Chenango.

ONONIS, in *Botany*, an ancient Greek name, occurring both in the works of Theophraſtus and Dioſcorides; but whether their Ονωνις is comprehended in the preſent genus we cannot confidently ſay. At any rate their plant was a ſort of Vetch, and of the ſame claſs and natural family with the preſent *Ononis*, and its name, derived from ονος, *an aſs*, and ονημι, *to delight*, implies that it was grateful food to thoſe animals.—Linn. Gen. 370. Schreb. 490. Willd. Sp. Pl. v. 3. 988. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 758. Ait. Hort. Kew. ed. 1. v. 3. 21. Thunb. Prodr. 129. Juſſ. Gen. 354. Lamarck Dict. v. 1. 505. Illuſtr. t. 616. Gærtn. t. 154. (Anonis; Tournef. t. 229.)—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, almoſt as long as the corolla; cloven into five, linear ſegments, ſlightly arched upwards; the loweſt under the keel. *Cor.* papilionaceous; ſtandard heart-ſhaped, ſtriated, depreſſed at the ſides more than

than the other petals; wings ovate, half the length of the ſtandard; keel acuminated, generally longer than the wings. *Stam.* Filaments ten, forming an undivided cylinder; anthers ſimple. *Piſt.* Germen ſuperior, oblong, villoſe; ſtyle ſimple, aſcending; ſtigma obtuſe. *Peric.* Legume turgid, rhomb-ſhaped, ſomewhat hairy, ſeſſile, of one cell and two valves. *Seeds* few, kidney-ſhaped.

Eſſ. Ch. Calyx in five linear ſegments. Standard ſtriated. Legume turgid, rhomboid, ſeſſile. Filaments in one undivided ſet.

Obſ. Only thirty-one ſpecies of this numerous and rather ornamental genus are enumerated in the 14th edition of the *Syſtema Vegetabilium;* fourteen of which, with the addition of *O. geminata*, are all that the firſt edition of the *Hortus Kewenſis* contains. Profeſſor Martyn deſcribes thirty-ſix ſpecies; and Willdenow, including thoſe of Thunberg from the Cape of Good Hope, has given ſixty-eight. Theſe are divided into five ſections, from each of which we purpoſe to give examples of the moſt intereſting, or handſome, plants.

Sect. 1. *Flowers nearly ſeſſile.*

O. *arvenſis.* Reſt-Harrow. Cammock. Sm. Fl. Brit. 758. Engl. Bot. t. 682. (O. ſpinoſa β, Linn. Sp. Pl. 1006.)—Stem hairy. Branches at length ſpinous. Flowers moſtly ſolitary. Leaves generally ſimple, entire towards their baſe. This is the only Britiſh ſpecies, and may be found very generally in the borders of barren, ſandy fields, by way ſides, and by the ſea-ſhore, flowering from June to September.—*Root* perennial, woody, blackiſh. *Stems* rather erect or procumbent, annual, round, woody, leafy, hairy, ſpinous when old. *Leaves* alternate, ſtalked, elliptically wedge-ſhaped, linear, roughiſh; the lower ones often ternate. *Stipulas* very large, ovate, embracing the ſtem, toothed. *Flowers* axillary, ſolitary, ſlightly ſtalked, elegantly roſe-coloured. *Seeds* dotted with tubercles.

With reſpect to the varieties of *O. arvenſis*, which have been conſidered as forming ſeparate ſpecies, Dr. Smith remarks, "We are perſuaded the *O. ſpinoſa*, Syſt. Veg. ed. 14. 651, is only the *arvenſis* or *inermis*, in an older or more ſtarved ſtate, and alſo that the *O. repens*, Linn. Sp. Pl. 1006, is merely a procumbent, maritime variety. *O. antiquorum* of Linnæus really appears not to differ from *arvenſis*." Willdenow thinks differently, but we cannot yield to his opinion without further means of judging reſpecting it.

O. *hircina.* Stinking Reſt-Harrow. Willd. n. 3. Jacq. Hort. Vind. v. 1. 40. t. 93.—Flowers ſomewhat ſpiked, in pairs. Lower leaves ternate; upper ſolitary, rather hairy. Branches villoſe.—Found in various parts of the continent of Europe. It flowers at Kew from May to Auguſt.—*Root* perennial, hard, woody. *Stems* procumbent in the lower part, aſcending upwards. *Leaves* ovate, acutely ſerrated, ſmooth above, hairy beneath. *Stipulas* ſerrated, embracing the ſtem. *Flowers* on very ſhort ſtalks, of a beautiful purple or red colour. *Legume* brown and rather hairy. The whole herb has a very ſtrong, diſagreeable ſmell, reſembling that of goats, and is never ſpinous.

O. *minutiſſima.* Small-flowered Reſt-Harrow. Linn. Sp. Pl. 1007. Jacq. Auſtr. v. 3. 23. t. 240. (O lutea ſylveſtris minima; Column. Ecphr. p. 1. 304. t. 301.)—Flowers lateral. Leaves ternate, ſmooth. Stipulas ſword-ſhaped. Calyx rough, longer than the corolla.—Native of the ſouth of Europe, flowering in June and July. *Root* perennial, woody, branched. *Stems* numerous, upright, generally ſimple. *Leaves* alternate, ſtalked, fringed with hairs. *Stipulas* lanceolate, pointed, glandular at the edge. *Flowers* ſeſſile, ſolitary, ſmall, yellow. Legume pointed, dark brown.

Sect. 2. *Flowers on awnleſs or ſimple ſtalks.*

O. *pubeſcens.* Linn. Mant. 267. Willd. n. 20. (O. Moriſoni; Gouan. Illuſtr. 47. Anonis purpurea procumbens verna ſeu præcox fruticoſa annua viſcoſa, ſiliquis craſſioribus lentiformibus rarius diſpoſitis; Moriſ. Hiſt. v. 2. 168.)—Flower-ſtalks very ſhort. Upper leaves ſimple. Stipulas ovato-lanceolate, entire.—Native of the ſouth of Europe, and found by Gouan in the Balearic Iſlands. *Stem* a foot high, branched, diffuſe, round. *Lower leaves* ternate; leaflets ovate or oval, obtuſe, acutely ſerrated. *Flowers* many together, chiefly towards the ends of the branches, purple. We know of no figure of this ſpecies. It is entirely covered with a ſort of viſcid downineſs.

O. *perſica.* Willd. n. 21. Burm. Ind. 157. t. 49. f. 1.—Stalks bearing two flowers, racemoſe. Leaves ternate, wedge-ſhaped, three-toothed. Spike leafy, terminal.—Native of Perſia. *Stem* ſcarcely a ſpan long, procumbent, looſely branched. *Leaflets* ſhortly ſtalked, wedge-ſhaped. *Stipulas* and *bracteas* lanceolate, embracing the ſtem. *Flowers* purple, in leafy, terminal ſpikes.

O. *laxiflora.* Willd. n. 38. Desfont. Atlant. v. 2. 146. t. 190.—Stalks ſingle-flowered, longer than the leaf. Leaves ternate, obovate, ſerrated. Stipulas roundiſh. Legumes villoſe, nodding.—Found upon the uncultivated hills at Algiers. *Root* annual. *Stem* erect, branched, hairy. *Leaflets* obovate, toothed, ſcarcely downy. *Flowers* axillary, ſolitary, inclining to a blue colour.

O. *ceniſia.* Linn. Mant. 267. Villars. Dauph. v. 3. 433. Allion. Pedem. v. 1. 319. t. 10. f. 2.—Stalks ſingle-flowered. Leaves ternate, wedge-ſhaped. Stipulas ſerrated. Stems proſtrate.—Native of Mount Cenis. *Stems* three or four inches long, ſlightly branched, ſmooth. *Leaflets* ſmooth, roundiſh at the end, delicately ſerrated. *Flowers* ſolitary, ſtriated, purple. Villars and Allioni conſider the *O. reclinata* of Linnæus to be merely a variety of this.

Sect. 3. *Flowers on awned or bearded ſtalks.*

O. *Cherleri.* Linn. Sp. Pl. 1007. Desfont. Atlant. v. 2. 148.—Stalks ſingle-flowered. Leaves ternate, toothed at the end, viſcid and hairy. Calyx longer than the corolla.—Native of Spain, Italy, and Barbary. *Root* woody. *Stem* procumbent, lax. *Leaves* nearly ſeſſile. *Stipulas* lanceolate, ſerrated. *Flowers* axillary, their *ſtalks* erect, but nodding with the *legume*.

O. *Natrix.* Linn. Sp. Pl. 1008. Curt. Mag. t. 329. (O. lutea; Camer. Epit. 445.)—Stalks ſingle-flowered. Leaves ternate, viſcoſe. Stipulas entire. Stem rather ſhrubby.—Found about hedges in France and Spain. *Root* large and wrinkled. *Stems* about a foot high, more or leſs erect. *Leaflets* oblong, toothed at the end. *Flowers* ſolitary, large, yellow, ſtreaked with red. The whole plant is viſcid, and has a reſinous ſmell.

Sect. 4. *Shrubby.*

O. *tridentata.* Linn. Sp. Pl. 1009. Cavan. Ic. v. 2. 41. t. 152.—Stalks two-flowered. Leaves ternate, fleſhy, ſomewhat linear, three-toothed.—Found in ſeveral parts of Spain. *Stem* a foot and half high, much branched; its *bark* white, downy, very ſlightly glutinous. *Leaves* ſtalked, glaucous. *Stipulas* ſhort, tapering. *Flowers* in terminal cluſters, roſe-coloured, on axillary, jointed ſtalks.

O. *fruticoſa.* Linn. Sp. Pl. 1010. Curt. Mag. t. 317.—Stalks about three-flowered. Leaves ſeſſile, ternate, lanceolate, ſerrated, ſtipulas ſheathing.—Native of mountains in Dauphiny, and other parts of the ſouth of Europe. This is a very beautiful low ſhrub, with numerous, woody *ſtems* about two feet high, jointed and branched. *Leaves* rather fleſhy, ſmooth, and ſhining. *Flowers* on long ſtalks, panicled,

panicled, terminal, about three together, large, lilac or roſe-coloured. Authors mention a variety of this ſpecies with white flowers,

O. *rotundifolia*. Linn. Sp. Pl. 1010. Curt. Mag. t. 355. —Stalks about three-flowered. Leaves ternate, roundiſh, toothed. Calyx of three, bracteated leaves.—Native of the Swiſs Alps. *Stem* round ſtriated, rather hairy, nearly two feet high. *Leaves* on ſtalks, ternate, the end leaflet larger and rounder than the others. *Stipulas* green, ſheathing, ſlightly ſerrated, ribbed. *Flowers* large and handſome, about three in a bunch, on long ſtalks, terminal, of a fine roſe-colour, though Miller, by miſtake, deſcribes them pale yellow. It is a taller plant than the laſt, with wider leaflets.

Sect. 5. *Dubious*.

In this ſection Willdenow enumerates ſix ſpecies, all taken from Thunberg's Prodromus, and natives of the Cape of Good Hope, and quite unknown to us.

Ononis, in *Gardening*, contains plants of the ſhrubby kind, of which the ſpecies principally cultivated are; the yellow-flowered ſhrubby reſt-harrow (O. natrix); the three-tooth-leaved reſt-harrow (O. tridentata); the ſhrubby reſt-harrow (O. fruticoſa); and the round-leaved reſt-harrow (O. rotundifolia).

But there are other ſpecies both of the annual and perennial kinds, that may be cultivated for variety.

The third ſort varies with white flowers.

Method of Culture.—Theſe plants may be increaſed by ſeeds, cuttings, and ſlips, according to the different kinds.

The ſeeds of the firſt ſort ſhould be ſown upon beds of light earth in the early ſpring, as about April, thinly in drills, when they ſhould be properly thinned out during the ſummer months, and kept perfectly free from weeds; when in the beginning of the autumn they may be removed into the places where they are to remain. It may likewiſe be increaſed by cuttings planted out at the ſame time.

But though this ſort is pretty hardy when the winters are not very ſevere, a few plants ſhould always be kept in the greenhouſe. And as it is apt to grow out of form it ſhould be kept well cut in, and new plants be frequently raiſed from ſeeds.

Theſe plants cannot be preſerved in pots. They do not flower until the ſecond year.

The ſecond ſort ſhould have the ſeeds ſown in pots and placed in a mild hot-bed, or on a very warm ſheltered border, in the early ſpring; but the firſt is the beſt method, the plants being afterwards managed as tender plants, having either the protection of the greenhouſe or of mats.

The third ſort is raiſed from ſeeds ſown either in pots or warm borders in the early ſpring months. It ſucceeds beſt in ſhady ſituations where the ſoil is of a ſandy quality. The potted plants are often introduced in greenhouſe collections; but they are capable of withſtanding the ſeverity of moſt winters in the open air.

And the fourth ſort ſhould have the ſeeds ſown in the early ſpring on an open border, the plants being afterwards properly thinned and kept clear from weeds. It may likewiſe be raiſed from ſlips planted out at the ſame ſeaſon. It is very hardy, and requires little trouble in its cultivation.

Theſe are all plants which afford ornament and variety in the borders, or among other potted plants of the greenhouſe kind.

ONONYCHITES, formed from ονος, *aſs*, and ονυξ, *hoof*, ſomething that has hoofs like the feet of an aſs.

Ononychites was an appellation which the heathens in the firſt century gave the God of the Chriſtians, becauſe they owned and adored the ſame God with the Jews.—For it was a notion (however it had its riſe), as appears from Tacitus, Hiſt. lib. v. cap. 3. that the Iſraelites, much afflicted with thirſt, were led to a ſpring by an aſs going to drink; and that, in gratitude for the benefit, they worſhipped an aſs; and that the Chriſtians did ſo likewiſe. See Tertull. Apol.

ONOPORDUM, in *Botany*, a name to be found in the works of Pliny, derived from ονος, *aſinus*, and πεδω, *pedere*. Profeſſor Martyn, by way of illuſtrating this derivation, ſays that it means *crepitus aſini*.—But from what cauſe this whimſical appellation is beſtowed on the preſent genus, it is difficult to determine. (See Lycoperdon.)—Linn. Gen. 409. Schreb. 538. Willd. Sp. Pl. v. 3. 1686. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 856. Prod Fl. Græc. Sibth. v. 2. 155. Ait. Hort. Kew. ed. 1. v. 3. 146. Juſſ. 173. Lamarck Dict. v. 4. 555. Illuſtr. t. 664. Gærtn. t. 161.—Claſs and order, *Syngeneſia Polygamia Æqualis*. Nat. Ord. *Compoſitæ Capitatæ*, Linn. *Cinarocephalæ*, Juſſ.

Gen. Ch. *Common calyx* roundiſh, ventricoſe, imbricated with numerous, ſpinous ſcales, prominent every way. *Cor.* compound, tubular, uniform; the florets hermaphrodite, equal, each of one petal, funnel-ſhaped; tube very ſlender; limb erect, ventricoſe, cloven into five equal ſegments, one of them more deeply ſeparated. *Stam.* Filaments five, capillary, very ſhort; common anther cylindrical, tubular, the length of the corolla, five-toothed. *Piſt.* Germen ovate; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma with a crown. *Peric.* none, except the permanent, ſlightly converging, calyx. *Seeds* ſolitary; down capillary, ſeſſile. *Recept.* ſcaly; the ſcales combined into cells, truncated, mucronated, ſhorter than the ſeeds.

Eſſ. Ch. Calyx ſwelling, its ſcales ſpreading and ſpinous. Receptacle cellular, a little ſcaly.

1. O. *Acanthium*. Cotton Thiſtle, or Woolly Onopordum. Linn. Sp. Pl. 1158. Engl. Bot. t. 977. Curt. Lond. faſc. 5. t. 57. Fl. Dan. t. 909.—Calyx-ſcales ſpreading every way, awl-ſhaped. Leaves ovato-oblong, ſinuated, woolly on both ſides.—This native of Britain, a very conſpicuous plant, occurs partially in waſte ground about towns, on a gravelly ſoil, flowering in July or Auguſt. —*Root* biennial, ſpindle-ſhaped. *Stem* erect, five feet high, branched, winged with decurrent, ſpinous *leaves*. *Flowers* terminal, ſolitary, erect, purple, very handſome and ſhowy. *Seeds* obovate, brown, ſhining; their down unequal, rough, deciduous, reddiſh.—The whole herb is clothed with a ſort of cottony web, which is eaſily rubbed off, and its ſeeds are ſaid to be a favourite food with the goldfinch, *Fringilla carduelis* of Linnæus.

2. O. *tauricum*. Tartarian Onopordum. Willd. n. 2. —Calyx-ſcales ſpreading every way. Leaves decurrent, ſmooth on both ſides, ſinuated, toothed, ſpinous.—Native of Tartary. Similar in habit to the laſt, but perfectly ſmooth in all its parts, and ſomewhat ſmaller.—This new ſpecies is given entirely on the authority of Willdenow, who drew his ſpecific character of it from a dried ſpecimen.

3. O. *macrocanthum*. Morocco or Long-ſcaled Onopordum. Willd. n. 3. Schouſb. Marocc. 198. t. 5.—Calyx-ſcales much ſpreading, as long as the calyx. Leaves decurrent, downy, ſinuated, toothed, ſpinous; radical ones pinnate.—Native of the empire of Morocco.—Dr. Sibthorp found it in the Archipelago.—This alſo is taken from Willdenow, who merely ſays that he ſaw a living ſpecimen

of it, and that it differs from *O. Acanthium* in having longer *calyx-ſcales*, and its radical *leaves* pinnate,

4. O. *illyricum*. Illyrian Onopordum. Linn. Sp. Pl. 1158. Jacq. Hort. Vind. v. 2. 69. t. 148.—Lower calyx-ſcales reflexed; upper much ſpreading. Leaves decurrent, downy, ſinuated, deeply toothed, and very ſpinous.—Native of the ſouth of Europe, flowering in July and Auguſt.—*Stem* ſix or ſeven feet high, branched from its baſe, broadly winged, and extremely ſpinous. *Leaves* long and narrow, ſcarcely exceeding the ſtem in width, of a greeniſh-white colour, deeply cut at their ſides into ovate or lanceolate ſegments, ſo as to be almoſt pinnatifid.—The habit of this magnificent ſpecies, whoſe purple *flowers* are ſaid by Jacquin to be ſometimes double the ſize of what he has figured, is alſo very ſimilar to that of the firſt ſpecies.

5. O. *deltoides*. Siberian Onopordum. Ait. Hort. Kew. ed. 1. v. 3. 146. Willd. n. 5.—Calyx ſquarroſe, webbed with down. Leaves ſtalked, ovate, angulated, downy beneath.—Native of Siberia. It flowers in Auguſt, and is perennial.—Introduced at Kew in the year 1784, by Mr. John Bell.—We know not that this is any where figured. The *leaves* reſemble thoſe of a Burdock.

6. O. *græcum*. Græcian Onopordum. Linn. Suppl. 349. Gouan. Obſ. 64. t. 25.—Calyx-ſcales ovato-lanceolate, mucronated. Leaves awl-ſhaped or lanceolate, decurrent, ſomewhat ſinuated, downy.—Native of the Levant. *Root* annual. *Stem* from one to three feet in height, very downy. *Radical-leaves* a foot or more in length, on a pinnatifid ſtalk, hoary with down. *Flowers* ſtalked, ſolitary, terminal, purpliſh.

7. O. *arabicum*. Arabian Onopordum. Linn. Sp. Pl. 1159. Jacq. Hort. Vind. v. 2. 70. t. 149.—Calyx-ſcales ovate, mucronated, adpreſſed. Leaves decurrent, rather downy, ſinuated, toothed, ſpinous.—Native of the ſouth of Europe, flowering in July.—This very handſome plant, whoſe large imbricated *calyx* is beautifully variegated, riſes to the height of ſix or eight feet. *Stem* erect, angular, hollow, branched. *Leaves* lanceolate, very ſharply ſpinous, beautifully veined and covered on both ſides with woolly down. *Flowers* erect, ſtalked, ſolitary, large, purple.

8. O. *uniflorum*. Single-flowered Onopordum. Willd. n. 8. Cavan. Ic. v. 1. 60. t. 88.—Stem none. Calyx cylindrical, ſeſſile; its ſcales ovate, mucronated, adpreſſed. Leaves ſtalked, woolly, toothed, ſpinous.—Native of Spain. *Root* ſpindle-ſhaped, brown. *Stem* none. *Leaves* all radical, nearly pinnatifid, covered with a white down, their ſegments terminated by a yellow ſpine. *Flower* ſolitary, ſeſſile. *Seeds* ſolitary, crowned with very long down. Willdenow remarks that this is ſimilar to the following, but that its leaves are not pinnatifid, whilſt its calyx-ſcales are mucronated and adpreſſed.

9. O. *acaulon*. Dwarf Onopordum. Linn. Sp. Pl. 1159. Jacq. Ic. Rar. t. 167.—Stem ſcarcely any. Calyx globoſe, nearly ſeſſile; its ſcales lanceolate, ſpinous, much ſpreading. Leaves on ſtalks, pinnatifid, toothed, ſpinous, downy.—Found by Dr. Sibthorp in Greece. It was cultivated in 1739, by Mr. Miller, and flowers in July and Auguſt.—*Root* biennial, ſpindle-ſhaped. *Stem* ſimple, about two inches long, terminated by a ſeſſile, red and white *flower*. *Leaves* cluſtered, of a beautiful glaucous hue, and ſpreading horizontally, ſo as to make the plant appear ſtemleſs.—Martyn conſiders the laſt ſpecies to be only a variety of this.

10. O. *rotundifolium*. Round-leaved Onopordum. Allion. Pedem. v. 1. 144. t. 38. f. 1. Willd. n. 10.—Stem nearly wanting. Calyx oblong, almoſt ſeſſile, its ſcales oblong-lanceolate, downy, without ſpines. Leaves ſtalked, roundiſh, heart-ſhaped, notched or toothed, without ſpines, downy.—Found in dry, ſtony places in Switzerland and Italy. *Root* thick and ſucculent. *Radical-leaves* about three or four, roundiſh, firm, thick, woolly and veined. *Flowers* compoſing a large, ſolitary, nearly ſeſſile, bell-ſhaped, head.

Profeſſor Martyn retains the *O. orientale*, Mill. Dict. n. 4. which is a native of Aleppo, and riſes with an upright, branching *ſtem*, ſeven or eight feet high. *Leaves* long and regularly ſinuated on their borders, like pinnatifid leaves. *Flowers* in large heads. *Calyx* very ſquarroſe and prickly.—Is it diſtinct from the following?

11. O. *elatum*. Tall Onopordum. Sm. Prodr. Fl. Græc. Sibth. v. 2. 156. Fl. Græc. (ined.) t. 833. (Carduus creticus, acanthi folio viridi et glutinoſo, flore purpuraſcente; Tourn. Cor. 31.)—Calyx-ſcales widely ſpreading, as long as the calyx. Leaves decurrent, ſinuated, toothed, ſpinous, hairy. Gathered in Crete by Tournefort and Sibthorp. *Root* biennial. Whole herb hairy all over, and of a green colour, not downy or woolly. The *flowers* are two or three inches broad.

ONORE, in *Geography*, a ſea-port town on the W. coaſt of Hindooſtan, in the country of Canara. When the Portugueſe firſt arrived in India, this town was the capital of a kingdom; which they firſt acknowledged as their ally and afterwards reduced to the condition of a ſubject. They erected a fortreſs for the ſecurity of their pepper trade; but the natives, aſſiſted by the Dutch, took it from them, and the influence of the Portugueſe long ago declined. In 1783 it was taken by ſtorm by the Britiſh troops, commanded by Gen. Matthews, and in 1799 it was ceded to Great Britain; 46 miles N.W. of Bednore and 15 from Pigeon iſland, which is in N. lat. 14° 1′. E. long. 74° 6′ 30″.

ONOS, in *Ichthyology*, a name given by ſome authors to the *æglefinus*, or common haddock. See Gadus *Æglefinus*.

Onos is uſed by Athenæus, and many other of the Greek writers, for the fiſh which we call the *hake*, the *aſellus minor* of authors, called by Bellonius, Geſner, and ſome others, the *merluccius*. See Gadus *Merluccius*.

ONOSANDER, in *Biography*, was a Greek author and Platonic philoſopher; concerning the period in which he lived nothing certain can be aſcertained, except that he flouriſhed under the Roman emperors. He wrote commentaries upon the "Politics" of Plato, which have not come down to us. He was likewiſe author of a work of much celebrity, entitled, "Στρατηγικος Λογος," being a treatiſe on the duties and virtues of a general of an army. This treatiſe was firſt publiſhed in a Latin verſion by Nicholas Saguntin, at Baſil in 1541. A new verſion of it was made by Joachim Camerarius, and publiſhed by his ſons at Nuremberg in the year 1595. In 1601 M. Rigault publiſhed an edition of it at Paris, in Greek and Latin, with notes, and ſince that time various editions and tranſlations of it have appeared. Moreri.

ONOSERIS, in *Botany*, ſo called by Willdenow, from ονος, *an aſs*, and σερις, *ſuccory*, apparently to preſerve ſome analogy with *Hyoſeris*, *Arnoſeris*, &c.; for there is no ſort of meaning in the particular application of the name to the plants in queſtion, of which he has framed a genus out of the Linnæan *Atractylis*.—Willd. Sp. Pl. v. 3. 1702.—Claſs and order, *Syngeneſia Polygamia-æqualis*. Nat. Ord. *Compoſitæ diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Eſſ. Ch. Receptacle nearly naked. Down of ſimple hairs. Calyx imbricated. Corolla radiated; the florets of the radius three-toothed.

1. O. *purpurata*. Willd. n. 1. (Atractylis purpurata; Sm. Plant. Ic. t. 65. A. purpurea; Linn. Suppl. 349.)—Leaves

Leaves lyrate, toothed; their terminal lobe haſtate.—Gathered by the celebrated Mutis in New Granada. Whether this plant be cauleſcent or not is uncertain, but the ſpecimen deſcribed ſeems to be the top of a woolly *branch*, crowned with ſeveral *leaves* and a branched *flower-ſtalk*. The *leaves* are a ſpan long, acute, ſharply toothed; their terminal lobe half their whole length. Their upper ſide is naked and peculiarly ſmooth; the under denſely woolly and ſnow-white. *Flower-ſtalk* longer than the leaves, clothed above with awl-ſhaped ſcales, reſembling thoſe of the calyx. *Flowers* purple, reſembling an *Aſter*, and near two inches wide when expanded. Their radiant *florets* are remarkable for a capillary ſpiral appendage, like an upper or inner lip.

2. O. *mexicana*. Willd. n. 2. (Atractylis mexicana; Linn. Suppl. 350. Sm. Plant. Ic. t. 66.)—Leaves lanceolate, entire.—Sent from the ſame country, by the ſame great botaniſt, to Linnæus. The *ſtem* ſeems ſhrubby, with long, ſimple, round, woolly, leafy branches. *Leaves* alternate, on ſhort woolly ſtalks, lanceolate, acute, entire, three inches long, ſingle-ribbed; ſmooth and ſhining above; white and woolly beneath, with glandular dots among the wool. *Flower* ſolitary, terminal, much like the laſt in ſtructure and colour, but rather ſmaller, and its radiant florets are deſtitute of the ſpiral lip.

Doubting the propriety of eſtabliſhing this genus, we have abſtained from giving its full natural character. See Atractylis.

ONOSMA, the name of a plant mentioned by Dioſcorides and Galen, derived, as it ſeems, from *οσμη, a ſweet ſmell*, or *ſavour*. Linnæus has arbitrarily applied it to the preſent genus.—Linn. Gen. 76. Schreb. 102. Willd. Sp. Pl. v. 1. 773. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 295. Juſſ. 130. Lamarck Dict. v. 4. 582. Illuſtr. t. 93. Gærtn. t. 67.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Aſperifoliæ*, Linn. *Borragineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in five lanceolate, erect, permanent ſegments. *Cor.* of one petal, bell-ſhaped; tube very ſhort; limb tubular and ſwelling, rather thicker than the tube; its border generally five-cleft; throat naked, pervious. *Stam.* Filaments five, awl-ſhaped, very ſhort; anthers arrow-ſhaped, erect, the length of the corolla. *Piſt.* Germen ſuperior, four-cleft; ſtyle thread-ſhaped, the length of the corolla; ſtigma obtuſe. *Peric.* none, except the unchanged calyx. *Seeds* four, ovate.

Eſſ. Ch. Corolla bell-ſhaped, with a pervious throat. Seeds four. Style the length of the corolla.

1. O. *ſimpliciſſima*. Siberian Simple Onoſma. Linn. Sp. Pl. 196. Gmel. Sibir. v. 4. 76. t. 40.—Leaves much crowded, linear-lanceolate, hairy. Fruit erect.—Native of Siberia, and on calcareous rocks by the Wolga. It flowers from April to June. *Stems* about a ſpan high, ſimple, woody, occaſionally with one or two branches at their baſe. *Leaves* greatly crowded together, ſo as to be almoſt imbricated, very narrow and attenuated at the baſe. *Flowers* terminal, white, generally in two cluſters, at the ends of the ſtems, ſcarcely ſtalked. The wild plant is never more than a foot high, and is ſoft to the touch.

2. O. *taurica*. Golden-flowered Onoſma. Pallas Tableau de la Tauride, 47. Annals of Bot. v. 2. 411. Sims in Curt. Mag. t. 889.—Stems ſimple, riſing from a ſpreading baſe. Leaves linear-lanceolate, with white hairs on both ſides. Fruit erect. Frequent in the open hills of Tauria, as well as on the mountains of the Caſpian Caucaſus, flowering in May and June. *Root* perennial. *Stem* upright, round, waved, hairy. *Leaves* ſolitary, alternate, fringed with hairs. *Flowers* in large, handſome, terminal, drooping cluſters, of a rich yellow, or golden colour.

3. O. *orientalis*. Oriental Onoſma. Linn. Sp. Pl. 196. Willd. n. 2. (Cerinthe orientalis; Amoen. Acad. v. 4. 267.)—Corolla cylindrical, acute. Leaves linear, hairy. Fruit pendulous.—Native of the Levant. It flowers in May and June. *Stems* round, hiſpid. *Leaves* alternate, ſeſſile, entire, hiſpid, with green or whitiſh hairs. *Flowers* on ſtalks, yellow, in a terminal double cluſter.

4. O. *echioides*. Hairy Onoſma. Linn. Sp. Pl. 196. Jacq. Auſtr. v. 3. 52. t. 295.—Corolla cylindrical, obtuſe. Leaves lanceolate, hiſpid. Fruit erect.—Native of the ſouth of Europe, flowering from March to June. *Root* perennial, long, ſimple, with a red bark. *Stem* generally a foot and half or two feet in height, much branched in the upper part, covered with pellucid, erect hairs or briſtles, each of which ſprings from a callous point. *Leaves* hairy; the lower ones attenuated towards the baſe; upper ſeſſile, ſomewhat heart-ſhaped at the baſe. *Flowers* yellow, in cluſters at the ends of the branches, reſembling the flowers of a *Symphytum*. The whole herb is very hairy.

Linnæus mentions a variety (*β*) of this ſpecies, and quotes it as figured in Column. Ecphr. t. 183. Dr. Smith however conſiders the plant of Columna as a diſtinct ſpecies. See his Tour on the Continent, ed. 2. v. 2. 325.

5. O. *tinctoria*. Deep-coloured Onoſma. Annals of Bot. v. 2. 410. (Cerinthe echioides; Scop. Carn. ed. 2. n. 197.)—Stem branched in the upper part. Leaves lanceolate-linear, hiſpid, green on both ſides. Fruit erect. Corolla longer than the calyx.—Native of paſtures in Tauria, flowering in the ſpring. This new ſpecies of *Onoſma* is greatly akin to the laſt, but differs in ſize, being of a more humble and ſimple habit. *Root* perennial, its bark ſtaining of a blood colour. *Leaves* ſomewhat narrower than in the laſt. *Flowers* ſmaller, pale, of a lemon-colour when old.

6. O. *ſericea*. Silky-leaved Onoſma. Willd. n. 4. Ait. Hort. Kew. ed. 2. v. 1. 296.—Leaves ſtalked, oblong-lanceolate, covered with ſilky hairs.—Native of the Levant. *Stem* quite ſimple, a ſpan high, white with down. *Leaves* oblong, acute, attenuated at the baſe and tip, thickly clothed on both ſides with hairs. *Corolla* dilated at the upper part.

7. O. *cærulea*. Willd. n. 5. (Symphytum orientale anguſtifolium flore cæruleo; Tourn. Cor. 7.)—Leaves ſeſſile, lanceolate, hairy and ſoft. Stamens longer than the corolla.—Native of Armenia. *Stem* a foot high, ſimple, white with down. *Radical-leaves* ſtalked; thoſe of the ſtem ſeſſile, ciliated at the margin. *Corolla* cylindrical, blue, dilated above.

Willdenow remarks that this is nearly allied to *Anchuſa lanata*, but that its leaves are not ſo woolly, nor is it furniſhed with a nectary.

8. O. *tenuiflora*. Slender Onoſma. Willd. n. 6. (Symphytum orientale echii folio, flore albo tenuiſſimo; Tourn. Cor. 6.)—Leaves ſeſſile, linear, obtuſe, hairy. Corolla cylindrical, a little longer than the linear calyx-leaves.—Native of the Levant. Diſtinct from every other ſpecies in the ſmallneſs of its *leaves*, which are linear, obtuſe, hiſpid, and ſcarcely the third of an inch in length.

9. O. *caſpica*. Caſpian Onoſma. Willd. n. 7. (O. orientalis; Pallas, It. v. 2. t. L.)—Stem branched, divaricated. Leaves oblongo-lanceolate, hiſpid. Flower-ſtalks axillary, when bearing the fruit reflexed. Corolla obtuſe.—Found in a ſandy ſoil on the borders of the Caſpian ſea. Willdenow ſays this is perfectly diſtinct from *orientalis*, in having a branched, diffuſe *ſtem*, its *flowers* axillary, and ſmaller.

10. O. *micrantha*. Small-flowered Onoſma. Willd. n. 8. (O. micranthos; Pallas. It. v. 2. app. n. 100. t. L.)—Stem branched, divaricated. Leaves ſtalked, oblong, white with hairs beneath. Cluſters naked. Native of ſandy places in Siberia.

Siberia. Willdenow tells us this may be eaſily known from all the other ſpecies by its *leaves* having very long ſtalks; its *cluſters* being terminal and compound, without any bracteas; and its *calyx* equal in length to the *corolla*.

ONOSMODIUM, ſo called by Michaux, as having a likeneſs to *Onoſma*, from which, according to that author, it differs in having a much ſhorter corolla, whoſe limb is acutely and more deeply divided, as well as leſs ſpreading, and the anthers ſeſſile, as well as leſs pointed. Michaux Boreali-Amer. v. 1. 132.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Aſperifoliæ*, Linn. *Borragineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in five deep, narrow, linear, erect, permanent ſegments. *Cor.* of one petal, oblong, ſomewhat bell-ſhaped; tube very ſhort; limb ſwelling, cloven half way down into five, half-lanceolate, acute, erect and approximated ſegments, whoſe margin is inflexed; throat naked, pervious. *Stam.* Filaments wanting; anthers five, ſeſſile, included, arrow-ſhaped, acute. *Piſt.* Germen ſuperior, four-cleft; ſtyle thread-ſhaped, much longer than the corolla; ſtigma ſimple. *Peric.* none, except the unchanged calyx. *Seeds* four, ovate.

Eſſ. Ch. Corolla ſomewhat bell-ſhaped, with a pervious throat; limb erect. Anthers ſeſſile. Seeds four. Style much longer than the corolla.

Michaux defines two ſpecies, which are herbaceous plants, with longitudinal ribs to their leaves.

1. O. *hiſpidum*. (Lithoſpermum virginianum; Linn. Sp. Pl. 190. L. latifolium virginianum, flore albido longiore; Moriſ. ſect. 11. t. 28. f. 3.)—Hiſpid. Segments of the corolla awl-ſhaped, very acute.—Native of Virginia. A hardy perennial in our gardens, flowering in June, but of no beauty to obtain general cultivation. Every part is clothed with rigid briſtles. *Leaves* lanceolate, or inverſely ovate, acute; clothed on the upper ſide with tubercles bearing hairs. *Corolla* whitiſh, about twice as long as the calyx.

2. O. *molle*. Mich. t. 15.—Downy. Segments of the corolla ſomewhat ovate.—Found in the country of Tennaſſée about Naſhville. *Mich.* This appears to have much reſemblance to the former, but the whole *herb* is hoary with ſoft whitiſh hairs. *Leaves* oblong-oval, with a central rib, and two pair of lateral ones, ſpringing more or leſs from its baſe. *Corolla* like the laſt, but with broader ſegments.

ONOVA, in *Geography*, a town of Hungary; 4 miles N. of Pancſova.

ONREAGH, a river of the county of Tyrone, Ireland, which riſes on the borders of Fermanagh, and flowing eaſtward, joins its waters to the Cameron.

ONRUST, a ſmall iſland near the coaſt of Java. This iſland lies about three leagues N.W. from Batavia. It is nearly round, riſing ſix or eight feet above the ſurface of the water, and of ſmall extent, being about 4800 feet in circumference. In the centre of the iſland, and within a fort, conſiſting of four baſtions and three curtains, ſtand the warehouſes and other buildings. On theſe fortifications, and on three ſmall outworks, conſtructed at the water's edge, are mounted 40 pieces of cannon of various ſizes. This fortified iſland is well ſituated to command the channel that affords the principal paſſage into the road. Whilſt this iſland was in poſſeſſion of the Dutch, the company had ten or twelve large warehouſes, almoſt always full of goods, conſiſting of pepper, Japan copper, ſaltpetre, tin, caliatour wood, ſapan wood, &c. under the direction of two adminiſtrators. On the north ſide of the iſland are two ſaw-mills, and on the ſouth ſide there is a long pier-head, on which are three large wooden cranes, erected for fixing maſts in ſhips, or for unſtepping them. Three ſhips can lie here, behind each other, alongſide of the pier, in deep water, to be repaired, or to receive and diſcharge their cargoes. There is another pier, a little more to the weſtward, called the Japan pier, where one more ſhip can lie, to load or unload. "It would be injuſtice," ſays captain Cook, "to the officers and workmen of this yard, not to declare, that, in my opinion, there is not a marine-yard in the world, where a ſhip can be laid down with more convenience, ſafety, and diſpatch, nor repaired with more diligence and ſkill." Although this iſland is but ſmall, the number of inhabitants is ſuppoſed to be near 3000, among whom are 300 European workmen. About 1600 feet from Onruſt is the iſland "de Kuiper," or "Cooper's" iſle, one-third leſs in ſize than the former, upon which the Dutch company had ſeveral warehouſes, in which coffee was laid up; and here are two pier-heads for loading and diſcharging ſhips. The iſland abounds with large tamarind trees, which afford an agreeable ſhade. To the eaſtward of Onruſt, and at twice the diſtance of Cooper's iſle, is the iſland "Purmerend," which is half as large again as Onruſt; planted with ſhady trees, and accommodating the diſeaſed who are ſent hither from Batavia with an hoſpital or lazaretto. "Edam" is another iſland about three leagues N.N.E. from Batavia, and about half an hour's walk in circumference; very woody, and having abundance of large and ancient trees. One of them, which is the banian-tree, and ſo large that 20 men, with their arms extended, cannot encompaſs it, is eſteemed holy by the Javaneſe, and much venerated by them. Stavorinus's Voyages, vol. i.

ONS, a ſmall iſland in the Atlantic, near the coaſt of Spain. N. lat. 42° 23'. W. long. 8° 55'.

ONSALD, a town of Sweden, in the province of Halland; 4 miles S.S.W. of Kongſbach.

ONSLOW, a maritime county of America, in Wilmington diſtrict, North Carolina, weſt of Cape Lookout; containing 5474 inhabitants, including 1757 ſlaves. Its chief town is Swanſborough.—Alſo, a townſhip of Nova Scotia, in Halifax county, at the head of the baſin of Minas; 35 miles N E. of Windſor; ſettled by emigrants from New England.

ONTARIO, one of the grand chain of lakes in North America, which divides the United States from Upper Canada; ſituated between 43° 15' and 44° N. lat., and 76° 30' and 80° W. long. It is of a nearly elliptic form, its greateſt length being from S.W. to N.E., and its circumference about 600 miles. The diviſion line between the ſtate of New York and Canada on the north paſſes through this lake, and leaves within the United States, according to Mr. Hutchins's calculations, 2,390,000 acres of the water of the lake. It abounds with excellent fiſh, particularly the Oſwego baſs, weighing three or four pounds. Its banks are in many places ſteep, and the ſouthern ſhore is covered principally with beech trees. The ſoil ſeems to be good. This lake communicates with lake Erie by the river Niagara: it receives the waters of Genneſſee river from the ſouth, and of Onondago at fort Oſwego, from the eaſt, by which it communicates, through Oneida lake and Wood creek, with the Mohawk river. On the north-eaſt it diſcharges itſelf into the river Cataraqui, which takes the name of St. Lawrence at Montreal, and by this river into the Atlantic ocean. Its iſlands are ſituated at the eaſtern end, and the chief of them are Wolf, Amherſt, Gage, and Howe iſlands.

ONTARIO, a large and fertile county of New York, bounded north by the above-deſcribed lake, weſt by the Genneſſee river, and ſouth by Steuben county. This county is well watered by the Genneſſee, and alſo by its tributary ſtreams, and a number of ſmall lakes. The chief

town is Canandarqua, ſituated at the north-weſt corner of Canandarqua lake, 15 miles W. of Geneva. The number of inhabitants is 12,584, of whom 57 are ſlaves.—Alſo, a county in Upper Canada, containing the following iſlands: *viz.* Tonti, called Amherſt iſland; Iſle au Forêt, called Gage iſland; Grand Iſle, called Wolfe iſland; and Iſle Couchois, called Howe iſland; and alſo all the iſlands between the mouth of the Garoqui to the eaſternmoſt extremity of the late townſhip of Maryſburg, called Point Pleaſant.

ONTARIO *Fort*. See OSWEGO.

ONTES, a town of France, in the department of Mont Blanc; 14 miles S. of Seyſſel.

ONTOLOGY, or ONTOSOPHY, the doctrine or ſcience *de ente*, that is, of being, in the general, or abſtract, together with the various and moſt univerſal modes or affections, as well as the ſeveral kinds or diviſions of it; for an account of which we refer to Watts's "Brief Scheme of Ontology." See alſo in this Dictionary BEING, ENS, ESSENCE, and EXISTENCE.

Ontology coincides with what in the ſchools is more uſually called *metaphyſics*; which ſee: and more lately, philoſophy of the mind, or *Mental* PHILOSOPHY; which ſee.

ONTONG JAVA, in *Geography*, a group of 22 iſlands in the Pacific ocean, called by Mendana "Bazos de la Candelaria," but now denominated "New Ireland." S. lat. 6° 15′. E. long. 156°.

ONTORIA, a town of Spain, in Aſturias, near the ſea; 45 miles E.N.E. of Oviedo.

ONUM, a town of Sweden, in Weſt Gothland; 36 miles E. of Uddevalla.

ONUPHIS, in *Ancient Geography*, a town of Egypt, and capital of a nome, called "Onuphites nomos," ſituated about the middle of the Delta, on the right bank of the canal called "Athribiticus Sinus," between Sebennytus and Butus.

ONYCHIA, in *Surgery*, from *ονυξ*, *a nail*, an abſceſs near the finger-nail, a whitlow.

ONYCOMANCY, or, as ſome write it, ONYMANCY, derived from *ονυξ*, *nail*, and *μαντεια*, *divination*, a kind of divination, by means of the nails of the fingers.

The ancient practice was to rub the nails of a youth with oil and ſoot, or wax, and to hold up the nails, thus ſmeared, againſt the ſun. Upon them were ſuppoſed to appear figures or characters, which ſhewed the thing required.

Hence, alſo, modern chiromancers call that branch of their art which relates to the inſpection of the nails, onycomancy.

ONYE, in *Geography*, a town of Hindooſtan, in Guzerat; 40 miles S.E. of Surat.

ONYX. The Greeks applied this term to a ſmall abſceſs of the eye, when it was ſhaped like the finger-nail.

ONYX, in *Natural Hiſtory*, the name originally given to the chalcedony with opaque ſtripes, of a pure white colour; and in later times applied to many agates, &c. with differently coloured ſtripes or zones. See the articles AGATE, CHALCEDONY, and GEMS.

ONYX, in *Conchology*, the name given by the curious to a ſpecies of voluta, found in cabinets, but never met with in that ſtate on the ſea-ſhores. The true account of this is, that the ſhell in this elegant form owes its appearance to art, having been poliſhed, and having had its outer coat taken off. With this outer coat, which is of a duſky yellow, it is often kept in the ſame cabinet under another name, being then called by the French, the cierge or wax ſhell.

ONYX, *Cyprea*. See CYPRÆA.

ONYX, in *Zoology*, a name by which Pliny and many other of the ancient writers have called the ſolen.

ONYX *Indicus*, in the *Materia Medica of the Ancients*, a term uſed by the Greek writers to expreſs what is uſually called *unguis odoratus*, or the ſweet hoof. Some call it *onychus indicus*, as particularly Myrepſus, in his antidote of fifty ſpecies. The ſame author mentions the blatta byzantia, and tells us that it is not the ſame thing with the onyx indicus, but that the Italians called by this name the os naſi, or bone of the noſe, of the purple fiſh. What he means by this is probably the bony tongue of that animal, nature having given it ſuch a weapon to pierce the ſhells of thoſe fiſh on which it is to feed. We frequently find the chamæ, and other ſhell-fiſh, with holes bored through the upper ſhell as exact as if it were done with an inſtrument: this has been done by the purple fiſh, to get at the fleſh of the animal within for food; and the bony tongue, with which this fiſh performs this, is called, by the Italians of thoſe times, blatta byzantia. Actuarius tranſlates the blatta byzantia of all the earlier writers by the phraſe os naſi purpuræ; and the interpreters of the Arabian writers give the ſame name to what they call unguis odoratus, or onyx indicus, for the Arabian name exactly expreſſes this.

ONZA, in *Geography*, a river of Africa, in the kingdom of Congo, which runs into the Atlantic, having a harbour at its mouth, but too ſhallow for navigation. It diſcharges itſelf at Moſſala, 140 miles S. from the Zaire, S. lat. 8° 10′.

ONZAN, a cape or point on the north coaſt of Braſil, oppoſite to cape St. Lawrence, forming jointly the points of Laguariba river; the former being on the weſt ſide of the river, which river is 10 leagues S.E. by E. of Bohia Baxa.

ONZATE, a town of Italy, in the department of the Mela; 5 miles S.S.W. of Breſcia.

ONZELLA, a river of Spain, which runs into the Aragon, at Sangueſa.

OOBA, a town of Japan, in the iſland of Niphon; 45 miles W. of Meaco.

OOBEEAN, a ſmall iſland in the Sooloo archipelago. N. lat. 66°. E. long. 120° 22′.

OOCHISRAVA, in *Hindoo Mythology*, is the name of a many-headed horſe, that, in the fabulous legends of India, aroſe from the ocean, when churned by gods and demons, as deſcribed under the article KURMAVATARA of this work. The reſult of this operation was the obtaining fourteen precious things, or gems, as enumerated in the article juſt referred to: among them the horſe, the ſubject of this. That, in the infancy of ſociety, the diſcovery of the value of this noble animal, and of the mode of applying his ſtrength and docility to the uſes of man, ſhould be the object of recorded gratitude, is ſufficiently reaſonable; but whether this be the intention of the fable in queſtion, we cannot decide. In pictures of the Kurmavatara, the horſe is uſually repreſented white, and properly ſhaped and proportioned, except in the additional heads, ſeven of which project from the front of the firſt. This item of the popular fable of churning the ocean is ſeldom mentioned in the writings of the Hindoos, excepting in deſcriptions of that operation. The white eight-headed horſe is ſometimes noticed as in the ſuite or poſſeſſion of Indra, the regent of the firmament. Some legends deſcribe this horſe as *ſeven*-headed: he then will appertain immediately to the ſun. See SURYA.

OOD, in *Geography*, a town of Sweden, in Weſt Gothland; 41 miles N.E. of Gotheborg.

OODA, a town of Japan, in the iſland of Niphon; 30 miles N.W. of Namba.—Alſo, a town of Japan, in the iſland of Ximo; 10 miles S.W. of Senga.

OODAPOUR, a town of Bengal; 16 miles E. of Comillah.

OODEADARGAM, a town of Hindooſtan, in Myſore, which gives name to a paſs taken by the Britiſh troops in 1800; 31 miles S.E. of Bangalore.

OODIMALLYCOTTA, a town of Hindooſtan, in Coimbetore; 17 miles E.S.E. of Animally.

OODNAGUR, a town of Bengal; 22 miles N. of Kiſhenagur.

OOFARA, a town of Japan, in the iſland of Niphon; 120 miles W. of Meaco.

OOGEIN, or Oojein. See Ougein.

OOISCONSIN, in *Geography*, a river of North America, which runs into the Miſſiſippi; N. lat. 42° 32′. W. long. 92° 3′.

OOKATA, a town of Japan, in the iſland of Ximo; 28 miles S. of Funai.

OOKI, a town of Japan, in the iſland of Ximo; 54 miles N. of Nangaſaki.

OOLANDOOR, a town of Hindooſtan, in the Carnatic; 20 miles W.S.W. of Trivadi.

OOLPAR, a town of Hindooſtan, in Guzerat; 10 miles W. of Surat.

OOMKOO, a mountain of Aſia, between Bootan and Bengal, N. of Buxadewar. It is higher than the Peachukom mountain, covered to its ſummit with trees, all clothed with moſs, and with creepers intertwined among them, of ſurpriſing length and thickneſs, and not leſs remarkable for their flexibility and ſtrength; qualities which render them an excellent ſubſtitute for rope, the uſe of which they entirely ſuperſede. This mountain is compoſed in ſome places of clay; but for the moſt part it conſiſts of a flinty ſtone, ſtriated with talc and intermixed with marble. It produces a great quantity of bamboo, which is very hollow, and ſmaller than that of Bengal, having its ſhoots at a greater diſtance from each other, and growing to full maturity in one ſeaſon. Its leaves are very large, and are gathered as food for their horſes inſtead of graſs: cluſters of plaintain trees were not uncommon. On one declivity of this hill is a ſacred ſpot called "Sheenſhilla," dedicated to a deity of the ſame name. Turner's Tibet, p. 45.

OONALASHKA, Unalashka, or *Agun-Alaſhka*, an iſland in the North Pacific ocean, ſeparated from the continent of North America by a channel in the direction of N.W. by N. This is one of the "Fox iſlands," and ſuppoſed to be the largeſt of them, and to contain ſeveral thouſand inhabitants. (See Fox *Iſlands*.) The houſes of theſe iſlanders are tents, like thoſe in Kamtſchatka, with an entrance by a hole in the middle of the roof. In one of theſe ſeveral families reſide, including thirty or forty perſons: they keep themſelves warm by means of whale fat, burnt in ſhells and placed between their legs: the women ſit apart from the men; and ſix or ſeven of theſe tents, called "Yourts," compoſe a village, of which there are ſixteen in Oonalaſhka. As their habitations are dark, they perpetually uſe, in winter, a ſort of large lamp, hollowed in a ſtone, into which they put a ruſh-wick, and burn train oil. The inhabitants are white, with black hair, having flat faces and being of good ſtature: the men ſhave with a ſharp ſtone or knife the circumference and top of the head, and the remaining hair is left to hang from the crown. The women cut their hair in a ſtraight line over the forehead, tying it behind, when it is of conſiderable length, in a bunch. Some of the men wear their beards, and others ſhave or pull them out by the roots. They mark their faces, the backs of their hands, and lower parts of their arms, with various figures, by pricking them firſt with a kind of needle, and afterwards rubbing the parts with black clay. In the lower lip they make three inciſions; placing in the middle one a flat bone, or coloured ſtone; and in each of the ſide ſlits they fix a long pointed piece of bone, which bends and reaches almoſt to the ears. They likewiſe make a hole through the griſtle of the noſe, into which they put a ſmall piece of bone, ſo as to keep the noſtrils extended. They alſo pierce holes in their ears, and wear in them any ſmall ornaments which they can procure. Their dreſs conſiſts of a cap and fur-coat, which extends down to the knee. Some wear caps of a party-coloured bird-ſkin, upon which is left part of the wings and tail. On the forepart of their hunting and fiſhing caps, they place a ſmall board like a ſcreen, adorned with the jaw-bones of ſea-bears, and ornamented with glaſs beads, which they procure in barter from the Ruſſians. At their feſtivals and dancing parties, they uſe a more ſhowy ſort of cap. Their coats are made and worn like ſhirts. The dreſs of the men is made of bird-ſkins, that of the women of ſea-otters and ſea-bears, neatly ſewed with ſinews, and ornamented with ſtripes of ſea-otter ſkins and leather fringes. They have alſo upper garments made of the inteſtines of the largeſt ſea-calves and ſea-lions. Their veſſels are of two ſorts: the larger being leather boats, or "baidars," with oars on both ſides, and capable of holding thirty or forty people: the ſmaller veſſels are rowed with a double paddle, and contain one or two perſons: they are a mere ſkeleton of a boat covered with leather, and yet they paſs in them from one iſland to another, and venture out to ſea to a conſiderable diſtance. In calm weather they go out to catch turbot and cod with hooks, and lines made with ſinews or feathers. Unſupplied by the fiſh and game they take with ſufficient ſuſtenance, their food conſiſts of ſea-wrack and ſhell-fiſh, which they find on ſhore. They generally eat the fleſh of all ſea-animals raw; and if they dreſs it they place it between two ſtones, ſtopping the interſtices with lime or clay, and kindle a fire under it. Their proviſions they keep undried without ſalt in the open air. They gather berries of various ſorts, and the root of the ſacanas, which grows wild at Kamtſchatka. They have not learnt the art of diſtilling brandy or any other ſtrong liquors from the cow-parſnip; they are fond of ſnuff, with which the Ruſſians ſupply them. Marriage ceremonies are unknown, but each man takes as many wives as he can maintain, generally four. Their weapons conſiſt of bows, arrows, and darts; for defence they uſe wooden ſhields, called "kayaki." Although ſavages, theſe iſlanders are very docile. The Ruſſians have for ſome years repaired to theſe iſlands for furs, of which they have impoſed a tax on the inhabitants. Beſides this tax they demand, in return for the fox-traps and ſkins with which they ſupply them, furs and proviſions for the winter; for the reſt they pay in beads, falſe pearls, goats' wool, copper kettles, halibets, &c. Capt. Cook and Capt. King viſited this iſland in the year 1778: the inhabitants ſeldom came to the ſhips, and did not remain above a quarter of an hour at a time, bartering a few articles with the ſeamen, but appearing to avoid much intercourſe. They are ſaid to have behaved with a degree of politeneſs uncommon with ſavage tribes. Several of the natives bartered a few fiſhing implements for tobacco. The ſhips excited their curioſity, though they did not appear to be altogether ſtrangers to Europeans: ſuch of them as could not come off in canoes, aſſembled on the hills to look at them. They were obſerved to eat raw fiſh. N. lat. 53° 45′ to 54°. E. long. 191° 20′ to 192°.

OONATO a town of Japan, in the iſland of Niphon; 120 miles N. of Jedo.

OONDAPATTY, a town of Bengal, in Baglana; 15 miles S. of Noaſſuch.

OONELLA, one of the Fox iſlands, about 7 leagues in cirumference, near the mouth of Samganoodha harbour in Oonalaſhka. The iſland of Acootan, E.N.E. of it, is conſiderably larger, and has ſeveral high mountains. See ACOOTAN.

OONEMAK, OONIMAK, or *Unimak*, one of the Fox iſlands, between Oonalaſhka and Alaſhka, about 200 miles in circumference. N. lat. 54° 30′ to 55° 15′. E. long. 194° 30′ to 196° 40′.

OONEMAK, *Cape*. See ONEMACK *Point*.

OONGONDA, a town of Hindooſtan, in Golconda; 35 miles S. of Combamet.

OONIARA, a large town of Hindooſtan, on the route from Agra to Oujein, ſurrounded by a wall partly of mud, partly of ſtone. Within the ſtone incloſure is a handſome houſe of the rajah: around both walls runs a ditch. The rajah is a feudatory of the rajah of Jynagur, to whom a tribute is paid of 35,000 rupees to the Siccar, and 5000 to the officers of government.

OONO, a town of Japan, in the iſland of Ximo; 25 miles W. of Funai.

OOOA, one of the ſmall Friendly iſlands; 12 miles N.E. of Annamooka.

OOREY, a town of Hindooſtan, in the circar of Gohud; 20 miles S.S.W. of Calpy.

OORGAUM, a town of Hindooſtan, in Dowlatabad; 15 miles E.N.E. of Amednagur.

OORITCHYCOTTAMALLY, a town of Hindooſtan, in Baramaul; 12 miles W. of Sankeridurgam.

OOROO, a kind of cloth made by the people of Otaheite, and of other iſlands in that neighbourhood, from the bark of the bread-fruit tree: the proceſs of its manufacture has been explained under the word AOUTA, which is a name given in thoſe countries to another kind of cloth, made of the bark of the paper-mulberry tree, preciſely after the ſame manner.

OORT, ADAM VAN, in *Biography*, was a painter of the Flemiſh ſchool, who enjoyed conſiderable reputation, but is made moſt remarkable by having had the honour of initiating the uncommon genius of Rubens in the art he practiſed.

He was born at Antwerp in 1557, and was the ſon of Lambert Van Oort, a painter of perſpective and architecture. Adam ſoon left his father's humble walk, and attempted hiſtory and portrait painting with ſucceſs; but he neglected the ſimplicity of nature, and having genius ſufficient to invent a ſyſtem of his own, too cloſely followed it to the loſs of juſt feeling and propriety.

It was not only in his painting that he was a manneriſt, but alſo in his diſpoſition; by the rough and unamiable humour of which, he loſt his friends and lived unhappily. Jordaens, who married his daughter, and who probably by his affection for her was induced to tolerate the rudeneſs of Van Oort's manners, was the only one of his numerous pupils who did not deſert him: yet he lived to the great age of 84, dying in 1557.

OOSCOPIA, ωοσκοπια, in *Antiquity*, a ſpecies of divination, wherein predictions were made from eggs.

OOSI, in *Geography*, a town of Japan, in the iſland of Niphon; 24 miles N.N.W. of Moriſa.

OOSIMA, a ſmall iſland of Japan, near the S. coaſt of Niphon. N. lat. 34° 26′. E. long. 139° 25′.

OOST, JACOB VAN, in *Biography*, a Flemiſh painter, born at Bruges about 1600, who travelled to Italy, and ſtudying with great attention the works of Annibal Carracci, ſucceeded in imitating his ſtyle of deſign in ſuch a manner as frequently to deceive. He died in 1671.

OOST, *Oaſt*, or *Ouſt*, in *Huſbandry*, a name given by the people who manure hops, to the kiln in which they dry them, after they are picked from the ſtalks. This is a ſquare room, built up of brick or ſtone, ten feet wide, more or leſs, and having a door on one ſide. In the midſt of this room is a fire-place, about thirteen inches wide, and as much high, and, in length, reaching from the mouth ſo nearly to the back part of the kiln, that a man has juſt room to go round it. This fire-place is called a *herſe*, and the fire is let out into the room by ſeveral holes in the ſides, in the ſame manner as in malt-kilns. Five feet above this is laid the floor, on which the hops are to be laid to dry; and this muſt have a wall round it of four feet high, to keep the hops from falling out. At one ſide of the upper bed muſt be made a window by which to puſh out the hops, as they are dried, into the room prepared for them. The beds muſt be made of laths an inch ſquare, placed at a quarter of an inch diſtance from one another, and ſupported by beams underneath. The hops are to be poured on this bed with a baſket, till the whole is covered half a yard thick with them; when this is done, lay them even with a rake, and let a fire be made in the fire-place below. Some recommend a wood fire, but experience ſhews, that nothing does ſo well as charcoal; let the fire be kept at the mouth of the furnace, for the air will be carried all the way through; and thus let the hops lie, never ſtirring them till they are thoroughly dry; when they rattle under the rake, and the inner ſtalks are brittle, they are ſufficiently dried, and are to be puſhed out, and a freſh parcel laid in the ooſt in their place.

The kilns for drying hops are built with fire-places, in the nature of malt-kilns; and at a proper diſtance over the fire is an hair-cloth ſtrained upon laths; and thereon the hops are laid and raked even, to the depth of about ſix or ſeven inches, for the better conveniency of drying them equally; and when they are properly cured on the under ſide, they are carefully turned; and by that means the upper ſide becoming the under, the whole ſhares the fire alike. The perſon that performs this part is called the dryer, whoſe buſineſs it is to manage the fires. The fuel commonly made uſe of is charcoal, on account of its freeneſs from ſmoke, and affording a ſteady heat. Great nicety is required in this part; a ſmall fire being to be made at firſt, that they may heat gradually, and ſo raiſed as they dry, that it may be done without ſcorching; and the fire is to be lowered by degrees, againſt they are ready to be taken off: the time required is about eight hours. From charcoal being dear, many people have adopted the method of drying with ſea-coal, upon what they call cockle-ouſts, which are ſquare iron boxes placed upon brick-work, and a flue and chimney in the back part of the building for the ſmoke to go off. The computation is, that a chaldron of ſea-coal, at about twenty-four ſhillings, will dry a load of hops, and that a load of charcoal will do no more. It is indeed expenſive to erect ſuch ouſts, as there muſt be no timber near them; and an iron beam and iron laths are to be uſed, and they covered with plates of tin or iron properly faſtened together. See TIN-*floor*.

But a new method of drying hops with ſea-coal or any kind of fuel whatever, by means of a moveable iron furnace, has lately been invented: it is in the form of an horizontal cylinder, ſtopped at both ends: it lies on an iron carriage, which rolls on four iron wheels; in the fore end of the cylinder is the furnace door; and a hollow iron flue runs in an horizontal direction along the upper ſurface of the cylinder from the back, till it reaches the fore end of it, when it takes a vertical direction, and is carried as high as is neceſſary to convey the ſmoke out of the ouſt. It is a ſort of rolling furnace.

OOSTBOURG, in *Geography*, a town of France, in the department of the Scheldt, and chief place of a canton, in the diſtrict of L'Ecluſe. The place contains 793, and the canton 4903 inhabitants, on a territory of 110 kiliometres, in ſeven communes.

OOSTERADE, a town of the duchy of Holſtein; ſeven miles E.N.E. of Itzchoa.

OOSTERDYKIA, in *Botany*. See CUNONIA.

OOSTERHOUT, in *Geography*, a town of Brabant; ſix miles N.E. of Breda.

OOSTERWYCK, a town of Brabant; ſeven miles S.W. of Bois le Duc.

OOSTERZEELE, a town of France, in the department of the Scheldt, and chief place of a canton, in the diſtrict of Ghent. The place contains 2740, and the canton 19,436 inhabitants, on a territory of 110 kiliometres, in 19 communes.

OOST-ROOSBECKE, a town of France, in the department of the Lys, and chief place of a canton, in the diſtrict of Courtray. The place contains 3540, and the canton 11,990 inhabitants, on a territory of 57½ kiliometres, in eight communes.

OOTAGAMIS, UPPER, a town of America, on the river Ooiſconſin, about 40 miles from the Miſſiſippi. N. lat. 42° 42'. W. long. 91 8'. The *Lower Ootagamis* lies at the conflux of the two forementioned rivers.

OOTAMA SCHOLAPERAM, a town of Hindooſtan, in Myſore; nine miles S.E. of Wombinellore.

OOTAMALLY, a town of Hindooſtan, in Coimbetore; 30 miles S.S.E. of Coimbetore.

OOTATORE, a town of Hindooſtan, in the Carnatic; 22 miles N.W. of Tanjore. N. lat. 11° 2'. E. long. 78° 58'.

OOTAWAS. See OTTAWAS.

OOTERAWOODY, a town of Hindooſtan, in Coimbetore; ſeven miles N. of Daraporum.

OOTIAMPALIAM, a town of Hindooſtan, in the country of Dindigul; 50 miles S.S.W. of Dindigul.

OOTIAMPALIAM, *Valley of*, a territory of Hindooſtan, encloſed between the branches of the Gauts, on the weſtern ſide of the peninſula, and extending 14 or 15 miles between the termination of the northern Gauts and the commencement of the ſouthern ones from Paniany to Coimbetore, before it opens finally into the low country on the Malabar coaſt. As it is well known, that ſhips which navigate this coaſt during the N.E. monſoon, commonly experience a ſtronger gale in the neighbourhood of Paniany than elſewhere, major Rennell is of opinion, that this opening in the Gauts is a very ſufficient cauſe for ſuch an effect; and as the lower part of the Coimbetore country partakes of the rainy or S.W. monſoon of the Malabar coaſt, this may be referred to the ſame cauſe.

OOTORI, a town of Japan, in the iſland of Niphon. N. lat. 34° 26'. E. long. 136° 40'.

OOTSOUR, a town of Hindooſtan, in Myſore; 30 miles E. of Rettinghery.

OPACITY, in *Philoſophy*, a quality of bodies which renders them opaque; that is, impervious to the rays of light.

The term *opacity* is uſed in oppoſition to *tranſparency*.

Opacity, according to the Carteſians, conſiſts in this; that the pores of the body are not all ſtraight, or directly before each other; or rather not pervious every way.

But this doctrine is deficient: for though it muſt be allowed, that, to have a body tranſparent, its pores muſt be ſtraight, or rather open every way; yet how it ſhould happen, that not only glaſs and diamonds, but even water, whoſe parts are ſo very moveable, ſhould have all their pores open and pervious every way; and, at the ſame time, the fineſt paper or the thinneſt gold plate ſhould exclude the light, for want of ſuch pores, is inconceivable. So that another cauſe of opacity muſt be found. Now all bodies have vaſtly more pores or vacuities than are neceſſary for an infinite number of rays to find a free paſſage through them in right lines, without ſtriking on any of the parts themſelves: for ſince water is nineteen times lighter, *i. e.* ſo much rarer than gold; and yet gold itſelf is ſo very rare, that magnetic effluvia paſs freely through it, without any oppoſition; and quickſilver is readily received within its pores, and even water itſelf by compreſſion; it muſt have much more pores than ſolid parts; conſequently, water muſt have at leaſt forty times as much vacuity as ſolidity.

The cauſe, therefore, why ſome bodies are opaque, does not conſiſt in the want of rectilinear pores, pervious every way; but either in the unequal denſity of the parts, or in the magnitude of pores, and their being either empty, or filled with a different matter; by means of which, the rays of light in their paſſage are arreſted by innumerable refractions and reflections, till, falling at length on ſome ſolid part, they become quite extinct, and are utterly abſorbed.

Hence cork, paper, wood, &c. are opaque; while glaſs, diamonds, &c. are pellucid. For in the confines or joining of parts alike in denſity, ſuch as thoſe of glaſs, water, diamonds, &c. among themſelves, there ariſes no refraction or reflection, by reaſon of the equal attraction every way; ſo that, ſuch of the rays of light as enter the firſt ſurface, paſs ſtraight through the body, excepting ſuch as are loſt and abſorbed, by ſtriking on ſolid parts; but in the bordering of parts unequal in denſity, ſuch as thoſe of wood and paper, both with regard to themſelves, and with regard to the air or empty ſpace in their larger pores, the attraction being unequal, the reflections and refractions will be very great: thus the rays will be unable to paſs through ſuch bodies, being continually driven about, till they become extinct.

That this interruption or diſcontinuity of parts is the chief cauſe of opacity, ſir Iſaac Newton argues, does appear hence; that all opaque bodies immediately begin to be tranſparent, when their pores become filled with a ſubſtance of equal, or almoſt equal, denſity with their parts. Thus paper dipped in water or oil, the ſtone called *oculus mundi* ſteeped in water, linen-cloth dipped in oil or vinegar, and other ſubſtances ſoaked in ſuch fluids as will intimately pervade their little pores, become more tranſparent than before.

On the contrary, the moſt tranſparent ſubſtances, by emptying their pores, or ſeparating their parts, may be rendered very opaque. Thus ſalts, or wet paper, or oculus mundi, by drying; horn, by ſcraping; glaſs, by pulveriſing, or flawing; and water itſelf, by being beat into bubbles or froth; are rendered opaque.

Indeed, to render bodies opaque, and coloured, their interſtices muſt not be leſs than of ſome determinate ſize; for the moſt opaque bodies that are, if their parts be very minutely divided, as when metals are divided in acid menſtruums, become perfectly tranſparent. See TRANSPARENCY.

OPAH, or KING-FISH, in *Ichthyology*, a ſpecies of fiſh common on the coaſt of Guinea; it is ſmooth-ſkinned, without ſcales or teeth; it has one erect fin to its back, which riſes below its neck, and reaches almoſt to its tail; there is alſo on each ſide, behind the gills, a fin; and a pair of fins a little before the vent under its belly; from behind the vent runs one fin within a little of the tail; and the tail-fin is large

large and forked; the eyes of this fiſh are large, the irides ſcarlet, encompaſſed with a circle of a gold colour, verged with ſcarlet; its noſtrils are placed above its eyes; the upper part of the body is of a dark blue, or violet colour; this, and the ſides which are of a bright green, are ſpeckled with oblong white ſpots; the chaps of a pale red; the noſe, gills, and belly of a ſilver colour; and all the fins of a bright ſcarlet; the mouth is ſmall, the tongue thick, and reſembling a human tongue, but thick-ſet with prickles, which are pointed backwards, and which ſeem to ſerve inſtead of teeth for retaining its prey or food. The fiſh from which this deſcription is taken, was three feet ſeven inches long, and three feet ten inches round in the thickeſt part, and weighed eighty-two pounds; the fleſh of the fore-part was firm, and had the appearance of beef, and the hinder part like fine veal. Phil. Tranſ. vol. xlvi. p. 518. or Abr. vol. xi. p. 879.

OPAL, Opalus, in *Natural Hiſtory*, a precious ſtone, of various colours; changeable according to the different poſition of the ſtone to the light.

It is generally claſſed among the ſiliceous earths, or finer flints, although ſome ſpecimens are ſo ſoft as to be capable of being ſcratched with a knife. M. Chaptal conſiders the opal as a ſemi-tranſparent agate of a milky whiteneſs, exhibiting a glittering, changeable, internal colour, of a blue, red, and green tinge. That which comes from Hungary has a kind of greyiſh clay for its gangre. The moſt beautiful opal is the oriental; ſometimes called the ſpangled opal, becauſe its colour appears like equal ſpots diſtributed over its whole ſurface. Theſe opals have received various names, according to the colours they reflect. The chatoyant ſtones, or ſuch as vary their colour according to the poſition of the light, and the eye of the obſerver, are varieties of the opal; ſuch are the giraſol, cat's-eye, and fiſh's-eye. The reflected rays of the giraſol are weak, blueiſh, and mixed with an orange yellow. This ſtone has been found in the lead mines of Chatelaudren in Britanny. The moſt obvious character of the giraſol is, that it exhibits in its internal part a luminous point; and reflects the rays of light in whatever poſition it may be turned, when it is cut into a globe or hemiſphere. The fiſh's-eye does not differ from the *Cat's-eye* (which ſee,) except in its colour, which is blueiſh: it is found at Java. See Gems.

Of opal there are four ſub-ſpecies, *viz.* the noble opal, infuſible before the blowpipe, ſp. grav. 2.114, and compoſed of 90 ſilex and 2 of water; common opal, infuſible without addition before the blowpipe, ſp. gr. 1.95 to 2.01, one ſpecimen compoſed of 98.75 ſilex, 0.1 alumine, 0.1 oxyd of iron, 0 water; and another conſiſting of 93.5 ſilex, 0 alumine, 1 oxyd of iron, and 5 water; ſemi-opal, infuſible in the furnace, ſp. gr. 2.54, compoſed in two ſpecimens of 43.5, or 35.5 ſilex, 0 or 1 alumine, 47. or 0.5 oxyd of iron, 0 or 0.5 lime, and 7.5 or 11.0 water; and wood opal, ſp. gr. 2.6, appearing to be wood penetrated with opal.

To imitate this gem in natural cryſtal uſe the following method: take yellow orpiment, and white arſenic, of each two ounces; crude antimony, and ſal ammoniac, of each one ounce: powder all theſe, and mix them well together; put this powder into a large crucible, and lay upon it ſmall fragments of cryſtal, and, upon theſe, other larger pieces of cryſtal; fill up the crucible with theſe, and lute on to it another crucible inverted, with a hole at the bottom as big as a ſmall pea; when the lute is dry, ſet the veſſel in a quantity of charcoal in a large chimney, covering them up with coals to the middle of the upper crucible: ſo long as the materials fume out at the hole, keep up a ſtrong fire; when that is over, let the fire go out of itſelf; and then unlute the crucibles; the greateſt part of the cryſtal will be found tinged to the colours of various gems; not only the opal, which will be very fair and beautiful, but the topaz and ruby colour will be ſeen in others.

A compoſition of ſemi-tranſparent white glaſs and paſte, reſembling the opal, may be formed by taking of the compoſition for hard Glass, or Paste, deſcribed under thoſe articles, ten pounds; and of horn, bone, or ivory, calcined to a perfect whiteneſs, half a pound: grind them well together, and fuſe them with a moderate heat. See art of imitating gems under the article Gems.

OPALIA, in *Antiquity*, feaſts celebrated at Rome in honour of the goddeſs Ops.

Varro ſays, that they were held three days after the expiration of the Saturnalia: according to Macrobius they were held on the nineteenth of December, which was one of the days of the Saturnalia. He adds, that thoſe two feaſts were celebrated in the ſame month, becauſe Saturn and Ops were huſband and wife; and that it is to them we owe the invention of corn and fruits: for which reaſon, the feaſt was not held till the harveſt and fruit-time were entirely over.

The ſame author obſerves, that the vows offered to the goddeſs were made ſitting on the ground; to ſhew, that ſhe was earth, the mother of all things.

OPALIN. See Magnesia *Opalina*.

OPALINKA, in *Geography*, a town of the duchy of Warſaw; 2 miles W. of Poſen.

OPARO, an iſland in the Pacific ocean, diſcovered by Capt. Vancouver in December 1791. Southward of the N.W. point is a ſmall bay, with a ſtrong beach, through which was the appearance of a conſiderable ſtream of water falling into the ſea. The ſhores were ſo ſmooth, that landing might have been effected without difficulty. Round to the N. of that point is a ſmall bay, in which are a ſmall iſlet and ſome rocks, behind which the ſhore may be very eaſily approached at any time. The S. extremity of the iſland appeared, in ſome points of view, to form a right angle, without the leaſt interruption in its ſides; about half a mile to the S.E. is a ſmall detached iſlet; the ſhores are interſperſed with ſandy beaches; its greateſt extent, in a N. 18° W. and S. 18° E. direction, is about 6½ miles, and it may poſſibly be about 18 in circumference. Its principal character is a cluſter of high craggy mountains, forming, in ſeveral places, moſt romantic pinnacles, with perpendicular cliffs, nearly from their ſummits to the ſea; in the intermediate chaſms there was no appearance of fertility or cultivation; they were chiefly clothed with ſhrubs and dwarf trees. The tops of ſix of the higheſt hills appeared like fortified places, reſembling redoubts, having a ſort of block-houſe, like an Engliſh glaſs-houſe, in the centre of each, with rows of paliſadoes, for a conſiderable way down the ſides of the hills, nearly at equal diſtances. Theſe ſeemed to be intended for advanced works, and apparently capable of defending the citadel by a few againſt numerous aſſailants. On all of them people were obſerved, moving about as if on duty. Theſe buildings were large enough to contain a conſiderable number of perſons, and they were the only habitations that were obſerved. Capt. Vancouver ſaw about 30 double and ſingle canoes, neatly conſtructed, though very narrow. The iſland did not appear to afford any large timber, the broadeſt planks of which the canoes were made not exceeding 12 inches. The total number of inhabitants on the iſland was eſtimated at not leſs than 1500. The natives appeared, notwithſtanding the uncultivated ſtate of the iſland, to be exceedingly well fed, of middling ſtature, very well made, with countenances open, chearful, and indicating hoſpitality. Their hair was cut ſhort, and they

were

were entirely without cloathing. None of them appeared to be tattooed. S. lat. 27° 36′. E. long. 215° 58′.

OPATCHIN, a town of Kamtſchatka; 30 miles from Bolchoretſk.

OPATOW, a town of Poland, in the palatinate of Sandomirz; 16 miles W.N.W. of Sandomirz.

OPATRUM, in *Entomology*, a genus of inſects of the order Coleoptera, the generic character of which is: Antennæ moniliform, thicker towards the tip; the head is projecting from a cavity in the thorax; the thorax is a little flattened, and margined; ſhells emarginate, longer than the abdomen. There are twenty-eight ſpecies ſcattered over the globe, one of which only is common to our own country, to Europe at large, and to America.

Species.

Griseum. Cinereous; thorax plane; ſhells with three raiſed lines, toothed behind. It inhabits Italy, and is larger than the Sabuloſum.

Porcatum. Grey; thorax plane; ſhells grooved, with raiſed black dots between the grooves. It inhabits Barbary.

* Sabulosum. This is a brown inſect; the ſhells have three indented raiſed lines; the thorax is emarginate. It inhabits Europe and America.

Gibbum. Black; ſhells with numerous obſolete raiſed lines. It inhabits Sweden, on ſand banks.

Lævigatum. Black; the ſhield is pitchy before; the ſhells are ſubſtriate. It inhabits New Holland.

Crenatum. Black; thorax with a crenate edge, the fore angle projecting, the hind one ſpinous; ſhells with crenate ſtriæ. It inhabits Sweden, on ſandy plains.

Glabratum. Black; thorax and ſhells ſmooth and cinereous. It is found in the Eaſt Indies, and is the ſize of the Sabuloſum.

Arenarium. Grey; ſhells ſtriate. It is found at the Cape of Good Hope.

Clathratum. Black; ſhells with punctured ſtriæ. It inhabits Cayenne.

Plagum. Depreſſed, black, opaque; ſhells ſtriate, ſmooth. It inhabits Siberia.

Granulatum. Black; edge of the thorax ſomewhat reflected; the ſhells have three raiſed lines, the interſtices punctured. It inhabits the ſandy plains of Barbary.

Orientale. Cinereous; thorax and ſhells rugged; foreſhanks dilated, triangular. It is found in the ſandy plains of the Eaſt.

Tibiale. Black; ſhells punctured, a little rugged; fore ſhanks two-toothed at the baſe.

Agricola. Black; thorax ſmooth; ſhells ſtriate. It inhabits Germany, and is a very ſmall inſect.

Minutum. Cinereous; thorax rough; ſhells with four raiſed lines. It is found in Sweden, and is very ſmall.

Pusillum. Cinereous, thorax rough; ſhells with many ſtriæ. It is ſmall and inhabits Hungary.

Quisquiliarum. Black; thorax granulate, ſmooth in the middle; ſhells very ſmooth.

Cinereum. This is black; clouded with cinereous; the ſhells have punctured grooves. It inhabits India.

Melinum. Ochraceous, ſmooth; thorax and ſhells faintly punctured. It is found in Germany, and is thought not to belong to this genus.

Cineterium. Bay, elongated; ſhells flat, very ſmooth. It inhabits Pomerania.

Bipustulatum. Ferruginous; ſhells faintly grooved. This alſo is found in Pomerania.

Lithophilus. Black, beneath ſcarlet; thorax ſcarlet, emarginate, pointed at the corners behind; the ſhells are very ſmooth; the tarſi are three-jointed. It inhabits Germany, and like the Melinum is of a doubtful genus.

Monilicorne. Brown; thorax and ſhells villous. It inhabits Germany.

Silphoide. Black, ſmooth; thorax dilated backwards; ſhells with punctured ſtriæ and two fulvous bands. It is found on the oak fungus.

Unipunctatum. Brown, hairy; thorax ſub-cylindric, emarginate, with a hollow in the middle; the two laſt joints of the antennæ diſtant and larger.

Bipunctatum. Brown; thorax ſub-cylindric, emarginate, with two hollows; the two laſt joints of the antennæ diſtant and larger.

Testaceum. This is a teſtaceous inſect; the eyes, thorax, ſhells, and antennæ are brown, the latter rufous at the baſe and tip; ſhells with a large teſtaceous lunule at the baſe; thorax with two impreſſed dots. It inhabits Europe; ſhells punctured and ſtriate.

Brunneum. Reddiſh-brown with yellow down; ſhells faintly punctured ſtriate, with ſix yellow ſpots; antennæ and legs pale yellow.

OPDAELSCHOW, in *Geography*, a town of Norway, in the province of Drontheim; eight miles S.W. of Drontheim.

OPDAL, a town of Norway, in the province of Drontheim; 54 miles S. of Drontheim.

OPE Land, in *Agriculture*, provincially ground that is looſe or open, from its being ploughed up every year, or kept in conſtant tillage.

OPECKON, in *Geography*, a creek of America, in Virginia, the water of which is diſcharged into the Patowmac river. N. lat. 39° 30′. W. long. 77° 52′.

OPEGINSKAIA, a town of Ruſſia, in the government of Novgorod, on the river Mota; 60 miles E. of Novgorod.

OPEGRAPHA, in *Botany*, ſo named from οπη, *a chink* or *cleft*, and γραφω, *to write* or *engrave*, in alluſion to the nature of the fructification, which reſembles Hebrew or Oriental characters on a white or pale ground; whence one ſpecies, and indeed many long confounded under it, obtained the appellation of *Lichen ſcriptus*, from Linnæus and his followers.—Perſoon in Uſt. Annal. faſc. 11. Ach. Prodr. 19. Meth. 16. Lichenogr. 244. Sm. in Engl. Bot. 1753.—Claſs and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ*, Linn. Juſſ. *Lichenes*, Achar.

Eſſ. Ch. Seeds in black, linear, ſeſſile, ſimple or branched, bordered clefts, in an uninterrupted cruſt.

No genus among the whole tribe of Lichens, now become a natural order, can be more clearly diſtinct than this. The *clefts*, technically ſo called, are a peculiar ſort of fructification, differing from the ſhields or tubercles of a *Lichen*, in their indefinitely oblong or linear form, and frequently branching nature, which laſt property ſeems a conſequence of the former. Their linear diſk, more or leſs intenſely black, is accompanied at each ſide by a parallel elevated border, ſometimes attended, rarely ſupplanted, by an acceſſory border from the ſubſtance of the cruſt. Theſe *clefts* are ſeſſile on, or ſometimes ſunk into, a continued cruſt, various in thickneſs, either membranous or chalky, moſtly white or pale, with a border more or leſs diſtinctly marked. The cruſt ſpreads in patches, generally over the ſmooth bark of trees, to which it is cloſely united, being rarely found on ſtones or walls.

Twenty-nine ſpecies of *Opegrapha* are defined in the *Prodromus* of Acharius, as a ſection of the great genus *Lichen*; in his *Methodus*, where *Opegrapha*, like the reſt of thoſe ſections,

ſections, is raiſed to the rank of a genus, they are reduced to 24, nor does the ſupplement to that work contain any new ones. In the more recently publiſhed *Lichenographia* of the ſame writer, we find 29 *Opegraphæ*, beſides eight ſpecies under a genus ſeparated therefrom by the name of *Graphis*, which appellation Adanſon originally gave to the whole, and it was retained by Ehrhart. There is moreover one ſpecies of each in the addenda.

The *Graphis* of Acharius is characteriſed by having the *clefts* ſunk into the cruſt, and their diſk naked, not covered by a black membrane; but the latter diſtinction ſeems to us very obſcure at leaſt, if not evaneſcent. There is certainly no natural difference or appearance to countenance this ſeparation.

Although ſome ſpecies of *Opegrapha* are defined with ſimple, and others with branched, *clefts*; even that difference is not invariable, examples of both being not unfrequent in the ſame individual, among the ſmaller leſs ſpecious kinds. Acharius has therefore, in his laſt work, laid it aſide, diſtributing the ſpecies according to the comparative breadth of their diſk.

The following examples may ſuffice.

O. *herpetica*. Eruptive Opegrapha. Ach. Lichenogr. n. 6. Meth. 23. Engl. Bot. t. 1789.—Cruſt tumid and ſomewhat rugged, browniſh olive grey. Clefts prominent, crowded, ſimple, oblong, convex, irregular.—Found by profeſſor Swartz in Sweden, and by Mr. Turner near Yarmouth, on the barks of trees. The uneven dirty olive cruſt diſtinguiſhes this ſpecies, which is one of the leaſt ornamental or attractive. The *fructification* is crowded over the ſurface, in little, coal-black, tumid, irregularly oval, wart-like *clefts*, very rarely cloven, never properly branched.

O. *Lyelli*. White-bordered Opegrapha. Engl. Bot. t. 1876.—Cruſt ſmooth, membranous, pale olive. Clefts prominent, turgid, crowded, curved, obtuſe, greyiſh and powdery, with an elevated, white, powdery border.—Diſcovered by Charles Lyell, eſq. on the rugged bark of trees in the New Foreſt, Hampſhire. It ſeems unknown to Acharius. The *cruſt* is very ſmooth, waxy in appearance, of an uniform pale olive green, and almoſt horny texture. The *clefts* are numerous and crowded, moſtly ſimple, various in length, curved, obtuſe or rounded at each end, very prominent; their diſk broad and convex, black, but clothed with greyiſh powder; their border very peculiar, originating from the cruſt, but white, powdery, and very thick.

O. *elegans*. Elegant Grooved Opegrapha. Engl. Bot. t. 1812.—Cruſt orbicular, granulated, white, ſomewhat ſhining. Clefts immerſed, ſcattered, divaricated, moſtly ſimple, with a grooved border.—This ſpecies, likewiſe, it ſeems, unknown to Acharius, was found by Mr. W. Borrer, on the ſmooth barks of young trees in Suſſex. Its peculiar character conſiſts in the proper border of the *clefts* being as it were double, divided by a longitudinal line or furrow, and there is a ſlight acceſſory border, from the cruſt, beſides. The *cruſt* is white and rather ſhining, all over granulated with regular minute prominences, but not mealy.

O. *ſcripta*. Black-letter Opegrapha. Ach. Meth. 30. Engl. Bot. t. 1813. (Graphis ſcripta; Ach. Lichenogr. 265. Lichen ſcriptus; Ach. Prodr. 25. Linn. Sp. Pl. 1606. Lichenoides cruſtâ tenuiſſimâ, peregrinis velut litteris inſcriptâ; Dill. in Raii Syn. 71. Muſc. 125. t. 18. f. 1?)—Cruſt thin, membranous, ſhining, ſmooth, greeniſh-white, bordered with black. Clefts immerſed, ſmooth, linear, ſlightly zigzag, ſimple, or much branched in a parallel direction.—Not uncommon on the even bark of trees in woods. The *cruſt* is broad and thin, of a greeniſh or browniſh-white, with a blackiſh edge. *Fructification* ſcattered, ſtrikingly reſembling Hebrew or Chineſe characters, which reſemblance is cauſed by the parallel, as well as frequently rectangular, direction of the numerous and various branches of the black linear *clefts*. Their diſk is paler than their borders, and eſteemed by Acharius to be naked. He enumerates five varieties of this ſpecies. Some of the *clefts* are ſimple, but they are always accompanied by ſuch as are much branched.

O. *dendritica*. Tree-like Opegrapha. Ach. Meth. 31. t. 1. f. 10. Engl. Bot. t. 1756. (Graphis dendritica; Ach. Lichenogr. 271.)—Cruſt tartareous, determined, very white and ſomewhat powdery. Clefts immerſed, depreſſed, without any elevated border, repeatedly branched, zigzag, tapering at each end.—Found in the ſouth part of England, by Mr. W. Borrer and Mr. Lyell, growing on the ſmooth bark of trees. The ſame, or a ſlight variety, was gathered in Spain, by Schouſboe. This is a moſt elegant plant. The cream-coloured, rather mealy, *cruſt* forms roundiſh patches, whoſe middle part principally is occupied by copious branched zigzag *clefts*, of a greyiſh-black, taper-pointed at each end, and ſpreading concentrically as it were toward the margin, which however they do not reach. They have no proper elevated border of their own ſubſtance, but the cruſt is ſlightly tumid at each ſide.

O. *aſtroidea*, Ach. Meth. 25. Engl. Bot. t. 1847, is now removed to the newer genus *Arthonia*, in Ach. Lichenogr. 144, where it makes the variety β of *A. radiata*.

OPEN, in *Geography*, a town of Pruſſia, in Ermeland; 14 miles W. of Heilſberg.

OPEN, the ſituation of a place expoſed to the wind and ſea. It is alſo expreſſed of any diſtant object to which the ſight or paſſage is not intercepted.

OPEN, in *Rural Economy*, a term ſometimes applied to cows or heifers, ſignifying that they are not in calf.

OPEN *Cuts*, in *Agriculture*, ſuch drains or gutters as are made in land by the ſpade, and left without being covered in. They are uſed in draining lands in particular caſes. And Mr. Nicol ſuggeſts, "that perhaps open cuts, if effectual, are the beſt of all for foreſt draining, as they cannot be inconvenient, from the plough not being employed after the trees are planted."

It is alſo found that cuts of this ſort are frequently uſeful in the practice of irrigation, watering, and floating.

OPEN-*Field Land*, that which is in a ſtate of commonage. It has been obſerved that the open field or unincloſed lands in ſome parts of the kingdom have undergone very little alteration in regard to the mode of occupation for ages. It is ſuppoſed, that to the ancient diſtribution of manors may be aſcribed the origin of what is now known in different parts of the kingdom by the name of open or common field lands, and in Scotland by that of runrig or rudridge. The ſcattered ſituation and ſmallneſs of the pieces of common field lands, ſtill frequently cultivated by one perſon, in many inſtances fifty or a hundred acres ſituated in nearly as many different places, evince, firſt, that the mode of diviſion, conſidering the then ſtate of the nation, was a matter of ſound policy, becauſe till about the cloſe of the ninth century, when England was divided into tithings and hundreds, there ſeems to have been no law but that of the ſword for the protection of private property; hence every inhabitant of the pariſh or townſhip, by having a common intereſt in the pariſh fields in caſe of any invaſion, became bound by the ſtrongeſt tie (ſelf-intereſt) to aſſociate with his neighbours in order to repel the foe. And in the ſecond place, it is alſo clear that the occupiers began with cultivating ſmall ſpots, an acre, or perhaps leſs, and, as population increaſed, and bread corn became ſcarce, they gradually increaſed their tillage lands.

Thoſe

Thoſe parts of the pariſh which were either unimprovable, or at too great a diſtance from home, were partly reſerved for the purpoſe of ſupplying fuel, pit-coal, if at all known, being only in common uſe in a few places. The remainder was allotted for the common paſturage of the pariſh cattle, which were by mutual agreement kept there during ſummer and harveſt; after which they were allowed to range over the arable lands till the return of ſpring.

It ought alſo to be obſerved that a certain portion of the manor or eſtate was ſet apart for the purpoſe of producing natural or meadow graſs to be made into hay. This meadow graſs was divided among the farmers, in proportion to the extent of their farms, either by lot or ſome kind of underſtood agreement. The cattle were excluded by mutual conſent at a certain period in ſpring, and it remained ſhut, as it is now termed, till hay harveſt was completed, after which the cattle were ſuffered to paſture during the remainder of the ſeaſon. It is aſtoniſhing that in ſuch a length of time as from the original diſtribution of manors in England to the preſent period, ſo little alteration ſhould have taken place in regard to the mode of occupying thoſe lands which remain in the open or common field ſtate, more eſpecially when it is conſidered that during this long interval a ſpirit for agricultural improvement ſeems at different periods to have become pretty general. In regard to the modes of cultivation which are adopted in reſpect to them, it is only neceſſary to remark, that previous to the introduction of turnips and artificial graſſes, the almoſt univerſal practice was to have three-fourths in grain, and one-fourth in fallow; and although, in ſome places, alterations have taken place, yet the inſtances are very rare in which a better ſyſtem is purſued.

Alſo the arable lands are divided into four fields as nearly equal as poſſible, and each of theſe fields (however many tenants may have an intereſt in the cultivation) muſt, by the eſtabliſhed rules, be wholly under the ſame kind of crop. This, added to the practice of paſturing their cattle on commons, will, according to Mr. Donaldſon, "for ever prevent the general introduction of artificial graſſes, or indeed almoſt any other ſpecies of improvement, till ſuch time as, either by the mutual conſent of all concerned, or the intervention of the legiſlature, the ſyſtem is entirely aboliſhed."

It is therefore evident, "that the open-field lands, which in ſome counties amount to above one-third of the whole, are deficient in point of produce at leaſt one half, when compared with that of incloſed lands under proper management. That open or common field huſbandry is therefore an obſtruction to agriculture, muſt be generally allowed, and an obſtruction ſo ſerious in its nature as to create a deficiency, on the ſuppoſition of there being one-fourth part of the tillage-land in this country in the open field ſtate, of at leaſt one-eighth of the marketable produce of the country. When this is ſtated, and when it is further added that no proprietor or tenant of open-field lands can introduce any improvements in the modes of cropping or of general management without the conſent of the pariſh-community of which he is a member, and none that can be binding upon them without an act of parliament, the abſurdity of allowing lands to remain in the open field ſtate muſt appear ſtill more glaring." And "ſome facts have been brought to light by means of the Board of Agriculture, which, in proof of theſe aſſertions, it may not be improper to mention. The report of the county of Buckingham contains the following ſtatement: 'About eighteen years ago, the pariſhioners came to an agreement, and obtained an act, to lay the ſmall pieces of land together.' One farmer, at that period, had eighteen acres in thirty-one different pieces, and at wide diſtances from each other. When the diviſion took place, the balks were, of neceſſity, ploughed up, by which a great portion of the ſheep-paſture was deſtroyed. It became then expedient, and it was agreed upon at a public veſtry to ſow clover and turnips as a ſuccedaneum for the balks. Two years ſince (that is, ſixteen years after this arrangement had taken place among the pariſhioners), one of the farmers, occupying ſixteen acres of theſe common fields, procured in the month of May a large flock of lean ſheep, which he turned on the clover crops, being then nearly in bloom, the greater part of which they devoured. Another inſtance of the impoſſibility of pariſhioners being able to arrange any mode by which improvements can be introduced, which individuals are bound to adhere to without the ſanction of parliament, is alſo detailed in the ſame report, in the following words: The pariſh of Steeple Claydon contains 2500 acres of ſtrong wet clay. The cuſtom is here, to have one crop and one fallow. About fourteen years ago the proprietors came to an agreement to have two crops and a fallow; but before the expiration of ten years, one of the farmers broke through the agreement, and turned in his cattle among the crops of beans, oats, and barley; in which plan he was ſoon followed by the reſt of his neighbours; and the crops on that part of the field, which, agreeable to the ancient cuſtom, would have been fallow, were in conſequence totally deſtroyed. Farther, "conſidering the immenſe national loſs ariſing from ſo great a portion of the cultivated and cultivable lands in this country remaining in the open field and commonable ſtate, the great additional expence which farmers are liable to in cultivating lands diſperſedly ſituated, and the inferiority of crops reaped from lands, however good in quality, that are ſubjected to a never-ending rotation of corn crops, it is no wonder that the report of every county in the kingdom ſhould contain an earneſt ſolicitation to the members of the Board of Agriculture, to ſuggeſt ſuch meaſures as are moſt likely to receive the ſanction of the legiſlature, and to meet the approbation of all the parties concerned, for removing obſtacles, which, while they are permitted to exiſt, muſt exclude the poſſibility of improving the agriculture of the country."

But, "to arrange general equitable principles, on which manorial rights can be purchaſed, and commons divided and rendered private property, and on which likewiſe proprietors of pariſhes ſhall be at liberty to incloſe, and to introduce new and better modes of huſbandry on their eſtates, are ſubjects of infinite importance to the future proſperity of the country; and as ſuch call loudly for the immediate intervention of the legiſlature."

Here, after ſtating and obviating the objections which have been ſtated againſt the dividing of commons and the incloſing of pariſhes, and after pointing out the advantages that experience has, in many inſtances, proved to have reſulted from adopting theſe means of improvement, what appears the moſt probable way in which they can be generally introduced? But it is ſuggeſted the depopulation of the country, which is ſuppoſed a neceſſary conſequence of diviſions of commons, or incloſing of pariſhes, is held out as a grand objection againſt the general adoption of either of theſe meaſures. The fact, however, it appears from the Agricultural reports, is quite the contrary; and to thoſe who attempt to argue againſt facts, it is unneceſſary to make any reply. Can thoſe meaſures tend to the depopulation of the country which have for their object the production in greater abundance of the means by which an increaſed population can be ſupported? Has not every farmer the power of cultivating his land to greater advantage when incloſed, or in ſeveralty, than when intermixed with that of others? Can any farmer cultivate his farm to the greateſt poſſible advan-

tage without more than ordinary labour? Does not this neceſſarily require an additional number of labourers? To all theſe queſtions the anſwers muſt certainly be in the affirmative. It may be admitted, that the inhabitants of a pariſh muſt undergo a very material alteration in their ſituation in conſequence of its being incloſed; yet it does not follow that the depopulation of the country muſt be the conſequence. Though ſeveral of thoſe who occupy ſmall farms muſt neceſſarily be removed, in order to enable the proprietors to claſs the lands into farms of a proper ſize, it is equally obvious, that a new ſet of people muſt be introduced; ſuch as hedgers, ditchers, road-makers, and labourers of every ſort. This may therefore be called an alteration in the deſcription of the inhabitants, a ſhifting of population from one pariſh to another, rather than an expulſion, or a decreaſe of the number of inhabitants in one particular pariſh. Were it evident, however, that depopulation was the conſequence of incloſing a pariſh, it will be found that that depopulation does not ariſe from the circumſtance of the pariſh having been incloſed, but from the total alteration of the ſyſtem that too commonly takes place in the after-management of the lands. If the lands, in the place of being laid down to graſs, as is the prevailing practice, were cultivated in an alternate courſe of grain and graſs huſbandry, the number of hands neceſſary for the cultivation, and for carrying on and following out the various improvements which in ſuch a caſe would be immediately introduced, would be at leaſt equal, if not greatly ſuperior, to that of the inhabitants at any period while it remained in the common or open-field ſtate.

The next objection againſt the adoption of either of theſe meaſures is, the depriving the commoners of their rights of commonage. This philanthropic argument is apt, with the man of humanity, like Aaron's rod, to ſwallow up every other that can be urged in favour of the public, or of the other individuals concerned. But let us pauſe a moment, and inquire what theſe rights are. It is preſumed, after the moſt minute inquiry, it will be found that the rights of commonage in this part of the country were, as in Scotland, veſted originally in the proprietors of the adjoining tillage lands; and that the new claimants of rights of commonage have acquired theſe rights, ſuch as they are, in almoſt every inſtance, through the negligence of the actual proprietors, who allowed theſe aſſumed rights to acquire the ſanction of the law, in conſequence of preſcription. That this is the origin of common rights in this part of the kingdom, and that they are more common on the crown-lands, ariſing from the cauſe now aſſigned, 'negligence,' will not be denied. But they are rights; and 'curſed be he that removes his neighbour's land-mark,' is a maxim that ought to be imprinted on the mind of every man. It does not, however, thence follow, that, to accommodate thoſe poſſeſſing rights of common, the public, or the principal proprietors, who would be benefited by a diviſion, ſhould ſacrifice their intereſt, ſhould allow the productive powers of theſe uncultivated waſtes to remain dormant, becauſe it is the inclination of thoſe who have thus acquired rights that they ſhould do ſo; far leſs does it follow, that, whether theſe rights have been acquired through legal indiſputable title, or through the ſufferance of the proprietors of the adjoining eſtates, the owners of them cannot, on the diviſion of a common, get a full and fair equivalent in property land for their rights of commonage. Whoever would maintain this doctrine, would maintain that the laws of England were framed for the protection of the rights of the rich, but that the poor had no intereſt in them. The advantages derived by the cottagers, in virtue of theſe rights, are, for the moſt part, merely ideal: yet, if ever a diviſion of the commons in England takes place, it will, for the reaſons mentioned above, become the indiſpenſable duty of the commiſſioners acting in ſuch caſes, both in point of humanity and ſound policy, to act liberally towards the cottager, and to give him an adequate allowance of property land for his preſcriptive rights. Commiſſioners ſo acting ought to conſider, that in a national view, whether A, B, or C, are the proprietors of theſe commonable lands, it is a matter of no ſort of importance, provided they are once put in the train of improvement, and which can only be done by converting them into property. Theſe commiſſioners ought farther to conſider, that ſcarcely any ſum of money they can award is an adequate compenſation for a cottager's right of common. The money may be ſoon diſſipated: but rights of paſturage, or lands in property, are funds more permanent in their natures. When a poor cottager receives a piece of money in compenſation for his rights of commonage, which is but too frequently the caſe under pariſh incloſure bills, the funds which were allotted for the ſupport of his family, are, as it were, ſet afloat: and it is a thouſand to one if they again ſettle on any friendly ſhore. It cannot, therefore, be too often repeated, that there is no compenſation a cottager can receive for his right of commonage ſo juſt and equitable, or to him and his family ſo beneficial, as land in property. Another objection to incloſing pariſhes, or to a diviſion of open fields, lands, or commons, is the expence of the act of parliament neceſſary to carry either of theſe meaſures into effect; and, when completed, to make the arrangement binding upon the parties. It is certainly mortifying to a proprietor that he can ſcarcely adopt any plan for improving his eſtate, without paying ſome hundred pounds to the clerks of parliament for doing nothing but regiſtering the edicts of the legiſlature; and for doing which, if they are not properly paid from the public funds, they at leaſt ought to be, ſo as to prevent them from levying a heavy tax on the more enterpriſing, public-ſpirited, and praiſe-worthy individuals of the community. Let litigious people, when they make appeals to the ſupreme tribunal of the nation, pay what the avarice of the official people may dictate; but let every application for the interpoſition of the legiſlative authority to ſanction meaſures calculated to promote the proſperity and improvement of the country, be laid before parliament without fee or reward. The only other objection which is noticed is, that if all the open fields and improvable commons were brought into a ſtate of cultivation, it would materially affect the intereſt of the owners of the already improved lands. Such a narrow-minded ſentiment ought to be treated with ſilence and contempt, did it not prove that thoſe who are capable of ſuggeſting it were ſatisfied, that however much individuals might ſuffer, the intereſt of the nation at large would be promoted, were every improvable acre in the iſland in a proper ſtate of cultivation. This being granted, it may be aſked, ought the intereſt of the public to be ſacrificed to promote that of a few individuals? But no apprehenſions need be entertained on that account. Although 'trifles light as air' ſeem with ſuch reaſoners to have the weight of 'words of holy writ,' yet the judicious and intelligent muſt be convinced, that while the commerce of Britain keeps on in a progreſſive ſtate, there is no extent of ſuperabundant produce that can be raiſed in the iſland which will not meet a ready ſale in ſome foreign market or other.

In reſpect to the advantages to be derived from a general diviſion of the commons, and the incloſure of the open-field pariſhes in this part of the iſland, although they are numerous, the moſt important of them are only mentioned. It is only

only in thoſe countries where the means of ſubſiſtence can be had in abundance, and on reaſonable terms, that population increaſes with rapidity. In political calculations the riches of a ſtate are eſtimated by the number of its inhabitants. As theſe cannot increaſe to any conſiderable degree where the means of ſubſiſtence are limited, it is evident, that by adopting the meaſures above-mentioned, by which only a great addition can be made to the national ſtock of proviſions, the ſtate would become richer, as it would then be able to furniſh from its own lands the means of ſupporting an increaſed population. Beſides, were theſe meaſures adopted, it is obvious that the national territorial revenue would be to an immenſe degree augmented; that of this part of the kingdom, in all prob. lity, one-third at leaſt beyond what it is at preſent. This fact is elucidated by the following extract from the writer's report of the county of Northampton: "The average rent of an acre of open-field land in this diſtrict, including the value of the tithes, which may be reckoned at three ſhillings and ſixpence the acre, may amount to eleven ſhillings and ſixpence; while that of an acre of incloſed land (including a ſimilar ſum for tithes,) may be reckoned at twenty ſhillings, which makes a difference of eight ſhillings and ſixpence the acre. There are eighty-nine pariſhes in this county in the open-field ſtate, which may contain nearly 150,000 acres; the rent which the proprietors therefore loſe, by keeping theſe pariſhes in the open-field ſtate, may be eſtimated at upwards of 60,000*l.* a-year; while at the ſame time an introduction of agricultural improvements is precluded, and conſequently an increaſe of rent on rational principles."

And beſides "an increaſe of population, of the quantity and quality of grain, and of territorial revenue, the improvement of the different ſpecies of live-ſtock is another advantage which uniformly reſults from incloſing land. The farmer, no longer under the neceſſity of mixing his herds or his flocks with thoſe of others, is at liberty to purſue ſuch meaſures as he judges moſt expedient; and while he purchaſes tups, bulls, and ſtallions of the beſt ſort, to improve his ſtock, he alſo takes care, by ſuperior cultivation, and a more judicious rotation of cropping than he was before at liberty to adopt, that they ſhall not be ſtinted in their growth by the want of provender. Such is the account of the advantages that are likely to reſult from a general diviſion of commons and the incloſure of open-fields, which the writer, from a careful peruſal of the agricultural reports of the different counties of England, and his own general knowledge of the ſubject, is able to lay before the reader. Experience having proved, in very many inſtances, that theſe, and ſeveral others of no inconſiderable importance, have actually reſulted, it muſt appear ſurpriſing that any peer of parliament ſhould ſtand up in his place and maintain an oppoſite doctrine; yet whoever peruſes the Parliamentary Regiſter for 1781, will find that this was the caſe."

Open *Flank*, in *Fortification*, is that part of the flank which is covered by the orillon.

Open *Fire*. See Fire, and Reverberatory.

Open *Fountain*. See Fountain.

Open *Hawſe*. When a ſhip at her moorings has her cables ſtraight to her anchors, without croſſing, ſhe is ſaid to ride with an *open hawſe*.

Open *Pound*. See Pound.

OPENACA, in *Geography*, a town of Ceylon; 38 miles S. of Candy.

Opening *a Vein*. See Phlebotomy.

Opening *of Trenches*, is the firſt breaking of ground by the beſiegers, in order to carry on their approaches towards a place. See Trench.

Opening *of Gates*, in *Aſtrology*, is when one planet ſeparates from another, and preſently applies to a third, bearing rule in a ſign oppoſite to that ruled by the planet with which it was before joined.

Opening *the Mouth*. See Mouth.

Opening-*Weirs*, are a ſort of moveable weirs or pens for the waters of rivers that are ſubject to floods.

OPERA, a dramatic and lyric repreſentation, in which all the fine arts conſpire to form a ſpectacle full of paſſion, and to excite, by the aſſiſtance of agreeable ſenſations, intereſt and illuſion.

The conſtituent parts of an opera are the poem, the muſic, and the decorations. The mind is addreſſed by the poetry, the ear by the muſic, the eye by the painting; and the whole ought to harmonize, in order to move the heart, and convey to it at once the impreſſion through different organs. Of theſe three parts, our ſubject does not permit us to conſider the firſt and laſt, but as they are connected with the ſecond; ſo that we ſhall immediately proceed to muſic, the ſecond conſtituent part.

The art of combining agreeable ſounds may be regarded under two different aſpects. Conſidered as an inſtitution of nature, muſic is confined to the pleaſure which reſults from melody, harmony, and rhythm; ſuch is, in general, the muſic of the church; ſuch are the airs for dancing, and for common ſongs. But as an eſſential part of the lyric ſcene, of which the principal object is imitation, muſic becomes one of the fine arts, capable of painting every picture, exciting every ſentiment, contending with poetry, giving it new force, embelliſhing it with new charms, and triumphing over it by enriching it with new beauties and new allurements. The ſounds of the *ſpeaking* voice, not being harmonical or ſuſtained, are ſo evaneſcent, and move in ſuch ſmall intervals, as not to be appreciable, and conſequently can never unite agreeably with the ſinging voice, and inſtruments that produce the ſame intervals; at leaſt in modern languages, too remote from the muſical character: for we are unable to underſtand many paſſages of the Greeks concerning their manner of reciting, but by ſuppoſing their language ſo accentuated, that the inflexions of ſpeech in a ſuſtained declamation form among themſelves muſical and appreciable intervals, ſo that we may ſay their theatrical pieces were a kind of opera; and it is even for this reaſon that we can have no opera properly ſo called among us. But if the declaiming ſpeech of the Greeks was not tuneful, what effects could be produced by the *Echeia*, or vaſes tuned to muſical intervals, in the theatres of the Greeks, as deſcribed by Vitruvius, lib. v. cap. 5?

Thus far Rouſſeau, whoſe ideas on the ſubject are always elegant and ingenious; but we fear they will never be fulfilled, at leaſt in France.

We muſt now trace the origin of muſical dramas, and point out by what gradations they have been brought to the acme of ſuch perfection as they have attained in Italy, Spain, Portugal, Vienna, Dreſden, Ruſſia, and London. The annals of modern muſic have hitherto furniſhed no event ſo important to the progreſs of the art, as the recovery or invention of *recitative*, or dramatic melody: muſicians till this period having been chiefly employed in gratifying the ear with "the concord of ſweet ſounds," without reſpect to poetry, or aſpiring at energy, paſſion, intellectual pleaſure, or much variety of effect. Epic poetry could never derive great advantage from muſic, or muſic from epic poetry: ſo long a poem as the Iliad, or Æneid, if we ſuppoſe either of them to have been originally ſung,

could admit of few embelliſhments or refinements from lengthened tones; it was the *lyric* poetry of the ancients as well as the moderns, conſiſting of ſhort effuſions of paſſion or ſentiment, in various meaſures, that beſt exerciſed the powers of muſical expreſſion. That narration which is ſung, like the epic poems of the ancients by the original bards, or their dependents the rhapſodiſts, as well as the hiſtorical ballads of later times, muſt have been ſet to the moſt ſimple and artleſs melody, or it would have been utterly unintelligible.

Pulci, who is regarded as the Ennius of modern Italy, and the firſt who attempted an epic poem in the language of that country, is ſaid by Creſcimbeni to have ſung his "Morgante Maggiore," at the table of Lorenzo de' Medici, in the manner of ancient rhapſodiſts, about the year 1450, by which we may conjecture, that the muſic was very ſimple.

As the Orfeo of Politian was certainly the firſt attempt at the muſical drama, which was afterwards perfected by Apoſtolo Zeno and Metaſtaſio, we ſhall give the reader a ſketch of the fable.

To this drama there is an argument in verſe. The piece is in five acts.

Ariſtæus, a ſhepherd, the ſon of Apollo, loved Eurydice, the wife of Orpheus, in ſo violent a manner, that he purſued her in the fields; and in her flight from him, ſhe was bitten by a ſerpent, of which ſhe died. Orpheus, by ſinging, ſo ſoftened the infernals, that they ſuffered her to depart, on condition that he would not look behind him. But not obeying this injunction, ſhe was forced back to hell. Upon his great grief, and reſolution never to love another female, the Thracian women tore him to pieces.

At the latter end of the 16th century, during all the rage for fugue, elaborate contrivance, and the laboured complication of different parts, without rhythm, grace, melody, or unity of deſign; the lovers of poetry were meditating the means of reſcuing her from muſical pedants, who, with a true Gothic ſpirit, had loaded her with cumbrous ornaments, in order, as was pretended, to render her more fine, beautiful, and pleaſing, after having fettered, maimed, and mangled her.

That no muſical dramas, ſimilar to thoſe that were afterwards known by the names of operas and oratorios, had exiſtence in Italy before the beginning of the 17th century, ſeems certain by no mention being made of them in the ample liſt given by Angelo Ingegneri, 1598, of all that were then known, in his diſcourſe on the repreſentation of dramatic fables and poetry, where he treats of *tragedie*, *comedie*, *paſtorali*, *piſcatorie*, *boſchereccie*, &c. all declaimed entirely, except the choruſes, which ſeem to have conſiſted of odes or madrigals, ſet to muſic in parts. Muſic is the *firſt* conſideration in operas and oratorios; but this author ſays at the end of his book, "I now come to muſic, the *third* and *laſt* part of dramatic repreſentations, which, in comedies and paſtorals, without choruſes, will be uſed at pleaſure, in interludes, between the acts, to relieve the ſpectators, whoſe minds may be fatigued by the attention they have beſtowed on the fable."

We are often told, however, of muſical dramas performed at Rome and Venice, long before this period: and every writer on the ſubject informs us, that Sulpitius, in his dedication of Vitruvius, ſpeaks of a tragedy that was recited and ſung at Rome, under the auſpices of cardinal Riario, 1480; that Alfonſo della Viola ſet a drama to muſic, in 1560, for the court of Ferrara; and that at Venice there was an opera performed for the entertainment of Henry III. of France, at his return from Poland, on the death of his brother Charles IX., 1574, which was ſet by the famous Zarlino. Theſe, and more, have been confounded by father Meneſtrier with the muſical dramas of later times, after the invention of recitative, which alone ſhould diſtinguiſh the opera and oratorio from every other ſpecies of theatrical exhibition; but theſe early attempts at ſinging were no more dramatic than a maſs, ſervice, full anthem, or madrigal, would be if ſung on a ſtage. Indeed, ſome of the dramas, which preceded the year 1600, had choruſes, and intermezzi in meaſured muſic, and incidental ſongs, like our maſques in the reigns of queen Elizabeth and James I., in which, however, the dialogue was all ſpoken.

Three Florentine noblemen, *viz.* Giovanni Bardi, count of Verona, Pietro Strozzi, and Jacopo Corſi, of good taſte in literature, being diſcontented with every former attempt at perfecting dramatic poetry and exhibitions, determined to unite the beſt lyric poet with the beſt muſician of their time; and therefore choſe Ottavio Rinuccini and Jacopo Peri, their countrymen, to write and ſet to muſic the drama of Daſne, which was performed in the houſe of ſignor Corſi, in 1597, with great applauſe; and this ſeems the true era whence the opera, or drama, *wholly ſet to muſic*, and in which the dialogue was neither ſung in meaſure, nor declaimed without muſic, but *recited* in ſimple muſical tones, which amounted not to ſinging, and yet was different from ſpeech, ſhould be dated. After this ſucceſsful experiment, Rinuccini wrote Euridice and Arianna, two other dramas for the ſame kind of muſic.

The revival of theatrical muſic was brought about by the invention of recitative, which is now univerſally received, practiſed, and preferred to the madrigal ſtyle, in which the words are ſo utterly unintelligible.

Peri, in his preface, after enumerating the great perſonages who were preſent at the repreſentation of the muſical drama of Euridice at Florence in 1600, and the eminent muſicians to whom his muſic had been ſhewn, tells us, that it was ſung by the moſt excellent performers of the time; among whom were ſignor Franceſco Raſi, a nobleman of Arezzo, who repreſented the part of Aminto; ſignor Brandi, Arcetro; and ſignor Melchior Palantrotto, Pluto. He then tells us, that "behind the ſcenes, ſignor Jacopo Corſi played the harpſichord; Don Garzia Montalvo the chitarone, or large guitar; Meſſer Giovambatiſta dal Violino the lira grande, or viol da gamba; and Meſſer Giovanni Lapi a large lute."

Theſe four ſeem to have compoſed the whole band. For though he celebrates the performance of Giovambatiſta Jacomelli on the violin, neither he, nor any one elſe, played on that inſtrument at the exhibition. He concludes his account of this drama by owning that ſome parts of it were compoſed by Giulio Caccini, detto Romano, "whoſe great merit was known to the whole world," becauſe it was to be ſung by perſons dependent on him; by which he probably means to ſay, that they were his ſcholars. He boaſts of having *opened the road* for others, by his eſſays at dramatic muſic.

Monteverde ſet Rinuccini's Arianna for the court of Mantua, in 1606; the words only were then printed, and reprinted ſeveral times after. This opera was performed at Venice, 1640, to Monteverde's compoſition, and the words again reprinted; but whether the muſic was ever publiſhed, we know not.

In a diſcourſe by Pietro della Valle on the muſic of his own time, addreſſed by that celebrated traveller to Lelio Guidiccione in 1640, and publiſhed in the ſecond volume of the works of Battiſta Doni, at Florence, 1763, there is an intereſting, clear, and admirable account of the ſtate of muſic in Italy, but particularly at Rome, during the beginning of the 17th century.

This

This agreeable writer, who had ſtudied muſic under the beſt maſters from ſeven years old, and who ſeems to have been an excellent judge of the ſubject, having differed in opinion from his correſpondent, who, in converſation, had aſſerted that muſic for 50 years back had been declining, and that there were no profeſſors left equal to thoſe of former times; La Valle endeavouring to prove, on the contrary, that, ſo far from having degenerated, it was in a ſtate much nearer perfection at the time he wrote, than at any former period.

If canons, fugues, inverſions, and all the artifices of elaborate and learned compoſitions are leſs practiſed in vocal muſic now, ſays the author, than formerly, it is becauſe they are ſo unfavourable to poetry, and the intelligence of what is ſung; for in fugues of many voices, there are as many different words as notes ſung at the ſame time, which occaſions ſuch confuſion, that it is utterly impoſſible to diſcover the ſentiment of the poet, which is the ſoul of the ſong, and that which chiefly makes a voice ſuperior to an inſtrument. If the words and the notes do not mutually help to explain and enforce each other, they are ill-matched, and unfit to be together. To the confuſion ariſing from all the parts ſinging different words at the ſame time, may be added the little attention to accent in fugues, where the ligatures and other accidents in harmony frequently throw the emphaſis on wrong words, and make long ſyllables ſhort, and ſhort long. Another inconvenience, or rather abſurdity, ſeems inevitable in vocal fugues of much ſubtilty and contrivance, where quick and ſlow, chearful and pathetic notes, are moving at the ſame time, which makes good performers unwilling to ſing them, as they can neither manifeſt taſte, nor ſenſe, in the execution.

The old maſters certainly were well acquainted with harmony, but few knew what uſe to make of it. Their compoſitions are full of the moſt artful and difficult inventions and contrivances, which the ear can neither taſte nor comprehend in the performance.

This is not the method by which modern maſters proceed: they have learned how to chooſe and reſpect good poetry, in ſetting which they relinquiſh all the pedantry of canons, fugues, and other Gothic inventions; and, in imitation of the ancient Greeks, aſpire at nothing but expreſſion, grace, and propriety.

The firſt good compoſitions that have been heard of this kind, in modern times, were Daſne, Euridice, and Arianna, written by Rinuccini, and ſet by Jacopo Peri and Monteverde.

In ſpeaking of the madrigaliſts of his own time, Valle ſays, though they had improved and poliſhed that ſpecies of compoſition far beyond thoſe of the preceding age, yet they grew every day in leſs requeſt than formerly; as the ſinging ſingle ſongs with taſte and expreſſion, accompanied by an inſtrument, was now preferred to four or five people poring over their books at a table, which ſeemed too ſtudious and ſcholaſtic for the entertainment of a company.

In the firſt operas, muſic was the principal object, with mythological characters in the fable. Machinery next took the lead, with perſpective and decoration; when it was impoſſible to tire an audience at a greater expence.

It was near 50 years before regular airs had admiſſion in theſe early muſical dramas. At firſt they were generally accompanied by the ſinger himſelf on the violin, harp, or violoncello; but during the mythological paſſion, and rage for machinery, the only wiſh of the impreſario was to dazzle the eyes, and ſtun the ears of the audience.

Gods and devils, heroes and heroines, and at length men and women, as hiſtory repreſents them, were brought on the ſtage. Theſe ſeveral reforms and changes of taſte in the public led at length to Apoſtolo Zeno and Metaſtaſio; when the exquiſite airs of Leo, Vinci, and Pergoleſi, with the great vocal talents of a Piſtocchi, Nicolini, Farinelli, the Fauſtina, and Cuzzoni, exalted the lyric ſtage to its higheſt degree of public favour.

Rouſſeau's reflections on the language moſt proper for muſic are all levelled at the French, and at their naſal, equivocal, and mute ſyllables. He has an excellent period on the imitations of painting and muſic: "Muſic imitates the ſentiments, painting the image of man."

Imitations in painting are always cold, from the want of that ſucceſſion of ideas, and thoſe impreſſions which heat and inflame the ſoul by degrees; whereas in painting, every thing is ſaid at the firſt glance. The imitative power of this art, with many apparent objects, is confined to very feeble repreſentations. It is one of the great advantages of a muſician, that he is able to paint things which cannot be *heard*, while it is impoſſible for the painter to delineate what cannot be *ſeen*; and the greateſt prodigy of an art, which has no other activity than its movements, is to be able to paint the image of repoſe, of ſleep, a calm night, ſolitude, and even ſilence, among muſical pictures. Sometimes noiſe produces the effect of ſilence, and ſilence the effect of noiſe: as when a man ſleeps at an equal and monotonous reading, and wakes the inſtant it ſtops; and it is the ſame for other effects. But the art has ſubſtitutions more fertile and more ſubtile than theſe. It can excite by one ſenſe ſimilar emotions to thoſe that can be excited by another: and as the relation can only be ſenſible by a ſtrong impreſſion, painting, in want of ſuch force, returns with difficulty to muſic thoſe imitations which ſhe has drawn from her. Let all nature ſleep, he who contemplates the ſight is not aſleep; and the muſician's art conſiſts in ſubſtituting, to the inſenſible image of the object, that of the movements which its preſence excites in the mind of the ſpectator. He does not repreſent the immediate object, but awakens in our minds the ſame ſentiment which we experience in ſeeing it. Rouſſeau goes deep into dancing. See BALLET.

Operas in general are not to be read or ſpoken, but to be ſung; and "nonſenſe well tuned" has at all times been heard with pleaſure. But there is agreeable nonſenſe, and there are pleaſing trifles. Muſic can pleaſe without words, as well as poetry without muſic: each has it votaries and diſtinct powers of affording delight. The union of both is certainly beſt; as the words, if they could be underſtood, might not only pleaſe but convey inſtruction. But there is a jealouſy between the two ſiſters, Muſic and Poetry, which prevents them not only from being kind relations, but good neighbours. Yet does not Poetry frequently beg aſſiſtance from Muſic to embelliſh both her tragedies and comedies with incidental ſongs, ſymphonies, choruſes, ſoft muſic, marches, act tunes, &c. even in her regular dramas that are declaimed, ſuch as Macbeth, the Tempeſt, Fair Penitent, &c. without Muſic thinking herſelf degraded by acting a ſubordinate part? And might not Muſic aſk the aid of her ſiſter Poetry, to furniſh her with impaſſioned words, as vehicles for her ſtrains as principal? If this were done reciprocally and cordially, with a ſincere wiſh to aſſiſt and exalt each other by turns, without envying and grudging every mark of approbation that is beſtowed on her rival, and regarding it as a robbery from herſelf, each might ſeverally diſplay her peculiar powers of charming and inſtructing by turns, without injury or degradation.

A lyrical drama is incomplete without muſic, which is not the caſe with a play written for declamation: yet people are diſſatisfied if an opera does not read in the cloſet as well

as a tragedy or comedy. Unreaſonable critics want to unite two things totally incompatible, ſtrength and energy with melodious ſoftneſs. They want black and white to harmonize, without tinging or deforming each other.

Verſes full of philoſophy and ethics, ſtrong reaſoning, bold metaphors, or epigrammatic wit, muſt be enfeebled by muſic, which conveys them ſlowly to the mind; though paſſion, ſentiment, graceful and pleaſing images and deſcriptions, are embelliſhed by it. Degrading poetry to elevate muſic, would be acting in a hoſtile manner to our own pleaſures. Let poetry be regarded as an intellectual pleaſure, if you pleaſe; and muſic be ranked, like painting, as an innocent gratification of ſenſe. There ſurely can be no more harm in liſtening with rapture to fine muſic well executed, than in regarding with delight and wonder a cartoon of Raphael, or a holy family of Correggio. Sublime poetry leaves the muſician nothing to do.

No people write about muſic more agreeably, or with reaſoning more ſpecious, than the French; and for themſelves, and their own powers of execution, it is more than ſpecious: for, ſinging out of the queſtion, it is oracular. In France, where the art of ſinging is unknown, at leaſt by their public ſingers, their dramas ſhould be calculated for declamation, by which they would be rendered more intereſting, and more impreſſive, than where ſinging is the principal talent to be diſplayed.

But when great ſingers are employed at an enormous expence, who have voices highly cultivated, and are poſſeſſed of uncommon powers of embelliſhing ſound, and of rendering muſic ſomething more than *vox pretereaque nihil*, why ſhould they be denied the opportunity of diſplaying their abilities, and the lovers and judges of muſic of receiving delight from their exertions? There is nothing immoral in ſound, if it is even connected with vice or immorality: it is by keeping bad company, and embelliſhing the ribaldry and nonſenſe of another art;—it is needleſs to ſay that *poetry* is in fault.

Opera *Buffa*, or *Burletta*, in *Italian Muſic*. It was the opinion of Muratori (Della Perf. Poeſ.), that a muſical drama or farce, called "L'Anfiparnaſo," written and ſet by the celebrated Orazio Vecchi, and acted and printed at Venice, 1597, was the origin of the *opera buffa*, or comic opera, in Italy; and that learned antiquary ſeems implicitly to have founded his opinion upon the author's own words; who, in the preface, ſays, that his performance is an "accoppiamento di comedia e di muſica, non più ſtato fatto, ch' io mi ſappia, da altri, e forſe non imaginato: A union of comedy and muſic, never attempted, to his knowledge, nor perhaps ever thought of before." The ſeveral Italian ſtates being under different governments, and having but little communication with each other, may account for Orazio Vecchi's ignorance of any attempt at a muſical drama before; but Muratori, in later times, ſhould have known what every ſtranger is able to learn from the general regiſter of dramas of every kind in the "Drammaturgia di Lioni Allacci," that beſides the Sacrifizio of Beccari, ſet to muſic by Alfonſo Viola, at Ferrara, in 1555, there are innumerable muſical dramas upon record of a higher date than l'Anfiparnaſo of Orazio Vecchi: as I Pazzi Amanti, rappreſentata in muſica in Venezia, 1569; La Poeſia Rappreſentativa, componimento per Muſica, Ven. 1574; La Tragedia, componimento, poeſia di Frangipani, muſica di Claudio Merula, Ven. 1574; La Poeſia Rappreſentata, componimento muſicale cantato in Venezia, l'anno 1578; Il Re Salamone, rappreſentatione muſicale, cantata in Ven. 1579; Pace, e Vittoria, rappreſentazioni cantata in muſica, in Ven. 1580; Pallade, componimento per muſica, in Venezia, 1581, and Il Fiore, rappreſentazione cantata in muſica, Ven. 1582, &c. moſt of which were probably ſung to the ſame kind of muſic as Vecchi's Comedia Armonica; but to none of them can the title of opera be accurately given, as they all preceded the invention of narrative melody, or recitative, which, in our opinion, can only conſtitute an opera ſerious or comic

The muſic of this piece is printed in a ſcore of five ſeparate parts, which are all employed throughout, even in the prologue, which in modern times is uſually a monologue. So that each ſcene is nothing more than a five-part madrigal in action: for though the whole is in meaſure, and in five parts, yet all the characters never appear on the ſtage together, except in the finale, or laſt ſcene. There are excellent wooden cuts at the beginning of every ſcene, by which the number of perſons employed in it, and their principal buſineſs appear.

This drama is neither mentioned by Creſcimbeni, nor in the Drammaturgia; and though Walther gives a liſt of twelve works, which Orazio Vecchi printed between the years 1580 and 1613, the Anfiparnaſo is not included. Nor is it enumerated among this author's works by his ſcholar, our countryman, Peacham. Vecchi ranked very high among the compoſers of his time; and, according to Santarelli, was the firſt who uſed the B *quadro* or ♮, not merely to expreſs the ſound B natural in the diatonic ſcale, to which it had till then been wholly confined; but as a moveable character, applicable to any other ſound that had been altered by a flat or a ſharp, which it has the power of reſtoring to its original pitch in the ſcale.

In the wooden cut preceding the prologue, and ſeveral ſcenes of the piece, as only one figure is repreſented, though the muſic is in five parts, the other four muſt have been ſung behind the ſcenes.

And as there is nothing like a ſolo air, or recitative, in the whole performance, it appears that the drama had not yet got out of the trammels of fugue, imitation, and perpetual chorus; and that ſo much of the church ſtyle was ſtill preſerved as to render modulation equivocal, and the keys difficult to determine by any rules in preſent uſe. The time, too, is as unmarked and doubtful as the modulation; and what little melody there is, by being divided among ſo many parts in diſſimilar motion, loſes its effect, and muſt have rendered the words unintelligible even to the natives of Italy.

As there is no overture to this or any of the firſt muſical dramas, we may ſuppoſe that the prologue ſupplied its place. Indeed, no part for an inſtrument of any kind is printed throughout the piece; conſequently, as there was no orcheſtra, there could be no ſymphonies or ritornels to the ſongs, or rather choruſes, of each ſcene.

Every movement throughout this drama begins in common time, and very ſeldom changes into triple meaſure. There are no bars, or flats and ſharps at the clef. But though it is very ſeldom that any other ſign than that for common time appears, as  , or  ; yet we are convinced that the meaſures muſt frequently have been changed, by agreement, in the performance, to make melody of ſome paſſages practicable; which, though extremely difficult and unmeaning in common time, become eaſy, pleaſing, and expreſſive in triple. And it is not perhaps ſo much from the change of ſtyle and general caſt of the melody, that we have loſt the expreſſion of old muſic, as from our ignorance of the time, not only of the movements, but of the notes themſelves, to which great latitude muſt frequently have been

given in the performance; though the compoſers had not diſcovered the art of expreſſing this latitude by the different characters or technical terms, which have ſince become general.

Vecchi lived in an age when an opportunity for fugue and imitation was irreſiſtible. In ſcenes of dialogue, ſuch contrivances might have been turned to account; but there is little diverſity of ſtyle or movement from the beginning to the end of the piece. The language is in general *Modeneſe*, and not intelligible even to many Italians.

In comparing Vecchi's muſic in five parts with that of Emilio del Cavaliere, Jacopo Peri, Giulio Caccini, and Claudio Monteverde, the legiſlators of dramatic muſic, it appears that Muratori has been guilty of two miſtakes in his account of Orazio Vecchi's muſical comedy: firſt, in ſuppoſing it to have been the earlieſt of the kind that was wholly ſung from the beginning to the end, without any mixture of declamation, as inſtances have been produced of eight anterior pieces of the ſame kind; ſecondly, in imagining that Rinuccini took this drama for a model, as the dramas which Emilio del Cavaliere ſet for Florence, ſo early as the year 1597, offered him an example of a ſpecies of muſic much more dramatic than the madrigal ſtyle of Vecchi, which was preciſely that which Rinuccini and his learned Florentine friend wiſhed to avoid.

When and where the firſt opera buffa was performed, *in ſtilo recitativo*, we have not been able to aſcertain. There was a mixture of comic characters in almoſt all the muſical dramas of the laſt century: however, in 1641, ſoon after the introduction of ſerious operas upon the Venetian ſtage, we find the comic opera of La Finta pazza, written by Claudio Strozzi, and ſet by Sacrati, and La Ninfa avara, written and ſet to muſic by Benedetto Ferrari, in the liſt of the muſical dramas of that year. And among thoſe performed at Rome and Bologna, about the ſame time, though the muſic is not eaſy to find, the words have been preſerved in many collections of poems. The famous opera of Orontea, firſt ſet by Ceſti in 1649, as mentioned elſewhere, was a tragi-comedy; as was the opera of Eriſmena, ſet by Cavalli in 1655, of which alſo an ample account, with ſpecimens of the muſic, have been given. But at this time, air, which was ſcarcely ſeparated from recitative, had not two diſtinct characters, as at preſent, for ſerious and comic purpoſes; for the ſubjects of comic operas, during the laſt century, were ſeldom ſo farcical as thoſe of modern burlettas, and therefore were leſs likely to ſuggeſt ſuch gay, groteſque, and frolickſome meaſures. Tragi-comedies in muſic had a very early admiſſion on the ſtage at Bologna, during the laſt century: as Andromeda Tragicomedia, ſet by Girolamo Giacobbi, maeſtro di capella of S. Petronio, and founder of the academy de' Filomuſi in that city, was performed in 1610, and Amore vuol gioventu, Scherzo drammatico, at Viterbo, 1659; Muſica di Giambatiſta Mariani, 1659. But the only real burlettas, which we have met with, are Girello, Dramma burleſca, ſet by Piſtocchi, 1672, which was repreſented at Venice by little figures of wax; I dui Diogeni, Dramma burleſca per Muſica, and Agrippina in Baja, Scherzo Drammatico per muſica, were both performed at Ferrara, 1687. Indeed, we learn but little of the burletta muſic of Italy, till the comic operas of Latilla, Ciampi, and Galuppi, were performed on our ſtage, of which we ſhall have occaſion to ſpeak elſewhere.

Opera-*Glaſs*, in *Optics*, is ſo called from its uſe in playhouſes, and ſometimes a *diagonal perſpective*, from its conſtruction, which is as follows. A B C D (*Plate* XVI. *Optics, fig.* 21.) repreſents a wooden tube about four inches long; in each ſide of which there is a hole E F and G H, exactly againſt the middle of I K, a plane mirror, which reflects the rays falling upon it to the convex glaſs L M, through which they are refracted to the concave eye-glaſs N O; whence they emerge parallel to the eye at the hole *r s*, in the end of the tube. Let P *a* Q be an object to be viewed, from which proceed the rays P *c*, *a b*, and Q *d*: theſe rays, being reflected by the plane mirror I K, will ſhew the object in the direction *c p*, *b a*, *d q*, in the image *p q*, equal to the object P Q, and as far behind the mirror as the object is before it; the mirror being placed ſo as to make an angle of 45 degrees with the ſides of the tube. And as in viewing near objects it is not neceſſary to magnify them, the focal diſtances of both the glaſſes may be nearly equal; or if that of L M be three inches, and that of N O one inch, the diſtance between them will be but two inches, and the object will be magnified three times, which is ſufficient for the purpoſes to which this glaſs is applied.

If the object be very near, as X Y, it is viewed through a hole *x y*, at the other end of the tube A B, without an eye-glaſs; the upper part of the mirror being poliſhed for that purpoſe, as well as the under. The tube unſcrews near the object-glaſs L M, for taking out and cleanſing the glaſſes and mirrors. The peculiar artifice of this glaſs is to view a perſon at a ſmall diſtance, ſo that no one ſhall know who is obſerved; for the inſtrument points to a different object from that which is viewed, and as there is a hole on each ſide, it is impoſſible to know on which hand the object is ſituated which you are viewing. The poſition of the object will be erect through the concave eye-glaſs. The common opera-glaſs is nothing more than a ſhort Galilean *teleſcope*; which ſee. See alſo Polemoscope.

Operation, in the general, the act of exerting, or exerciſing ſome power, or faculty, upon which an effect follows.

The nobleſt operation of man is that by the ſchoolmen called *vital*, or *immanent*; *viz.* the operation of the mind; which, with regard to the underſtanding, is threefold; apprehenſion or perception, diſcretion or judgment, and reaſoning or diſcourſe.

The direction of theſe makes the object of logic.

With regard to the will, the immanent operations are willing and nilling: to which are referred loving and hating.

Operation, in *Medicine*, denotes a methodical action of the hand on the human body: in order to re-eſtabliſh health.

Bleeding is a very common, but, at the ſame time, a dangerous operation.

Trepanning is one of the fineſt operations in ſurgery.

The Cæſarean operation is the cutting open of a woman with child, and drawing out the child through the aperture.

The other chirurgical operations are ſutures, tapping, caſtrating, cutting for the fiſtula, amputation, extirpation, cupping, &c. See Suture, &c.

Operation, *High*. See High and Lithotomy.

Operation, *Lateral*. See Lithotomy.

Operation is more particularly uſed, in *Medicine*, for the means by which any remedy produces its ſalutary effect; or that ſeries of actions, mediate and immediate, by which its remote end is attained.

See the operations of each kind of medicines under the proper heads, Specifics, Purgative, Emetics, Opiates, &c.

Operation, in *Chemiſtry*, denotes the proceſſes, or experiments, by means of which the proper changes are produced in bodies, and the effect of the art procured.

The changes chemiſtry produces in bodies, are reducible

to

to two kinds; *viz.* an union of parts, and a ſeparation of them: thus chemiſtry either ſeparates ſpirits, ſalts, oils, &c. or compounds them together.

A chemical operation, then, conſiſts in changing the ſituation of the parts; particularly, either in moving ſome parts, but not the whole, which is called *ſeparating;* or, in adding new parts, which is called *uniting*.

All chemical operations, therefore, are reducible to two general kinds: *viz.* ſuch whereby the parts of bodies, before joined or united, are ſeparated, which the ancient chemiſts called *ſolution;* and ſuch whereby the parts, before disjoined, are combined or united, called *coagulation*.

Some, however, object digeſtion as a third ſpecies of operation, not reducible to either of them; but Boerhaave ſhews, that it is a compoſition of both.

Moſt chemiſts, however, look on this diviſion as ſcarcely accurate and minute enough, and ſubdivide the art into a number of particular or ſubordinate operations; as calcination, vitrification, diſtillation, ſublimation, cohobation, amalgamation, fermentation, putrefaction, &c.

Operation, in *Theology*, is uſed for the actions, both of the Word and the man, in Jeſus Chriſt. See Person.

The orthodox teach, that there are two operations in Jeſus Chriſt, the one divine, the other human; and not one *theandric* operation, as was the doctrine of the Monothelites and Monophyſites.

OPERATOR, in *Surgery*, &c. a perſon who operates, or works with the hand, on the human body, to preſerve or reſtore its health.

We ſay an *operator for the ſtone*, meaning a lithotomiſt, or a perſon who cuts.

Operator *for the Eyes*, denotes a perſon who couches cataracts, &c.

Operator *for the Teeth*, ſignifies a tooth-drawer, &c. See Teeth.

OPERBANDA, in *Geography*, a town of Bengal; 25 miles N.W. of Nagore.

OPERCULARIA, in *Botany*, a genus of Gærtner's, whoſe name is derived from *operculum*, a lid, becauſe the ſeeds are fixed to the bottom of the lid or covering of the receptacle.—Gærtn. t. 24. Schreb. 65. app. 819. Willd. Sp. Pl. v. 1 563. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 232. Lamarck Dict. v. 4. 560. Illuſtr. t. 58. (Pomax and Rubioides; Soland. MSS.)—Claſs and order. *Tetrandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juſſ.?

Gen. Ch. *Cal.* Common perianth of one leaf, bell-ſhaped, permanent, containing three or ſix flowers, with ſix or nine acute, unequal teeth; proper perianth none. *Cor. univerſal* equal; *proper* of one petal, funnel-ſhaped, with a four or five-toothed, erect mouth. *Stam.* Filaments four, inſerted into the receptacle; anthers diſtinct. *Piſt.* Germen inferior, immerſed in the receptacle; ſtyle thread-ſhaped; ſtigma thickiſh, cloven. *Peric.* none. *Seeds* ſolitary, convex on one ſide, furrowed on the other. *Recept. common* deciduous, flat above, cloſing the aperture of the calyx below the teeth; pyramidal below, furrowed and angular; the angles continued into partitions, by which the cavity of the calyx is divided into as many cells as there are ſeeds.

Eſſ. Ch. Common calyx bell-ſhaped, ſix or nine-toothed, with three or ſix flowers. Partial calyx none. Partial corollas four or five-cleft, equal. Seeds ſolitary, immerſed in the receptacle.

1. O. *umbellata*. Willd. n. 1. Gærtn. t. 24. (Pomax umbellata; Soland. MSS.)—Flowers umbellated, monandrous.—Native of New Holland. *Stem* round, hairy, with oppoſite branches. *Leaves* oppoſite, ſtalked, oblong, hairy on both ſides. *Flowers* terminal, umbellated. This ſpecies is remarkable for having three ſeparate, three-toothed flowers in the diſk; a ſingle ſtamen; and occaſionally two ſtyles.

2. O. *aſpera*. Willd. n. 2. Gærtn. t. 24. Juſſ. Annales de Muſ. v. 4. 427. t. 70. f. 1. (Rubioides aſpera; Soland. MSS.)—Flowers capitate. Calyx furrowed, ſmooth. Native of New South Wales. Introduced at Kew in 1790, by ſir Joſeph Banks, where it flowers in June and July.—*Stems* upright, forked, round, furrowed, ſmooth. *Leaves* oppoſite, ovato-lanceolate, entire, ſmooth, veined. *Flowers* capitate, terminal, drooping.

3. O. *paleata*. Young in Linn. Soc. Tranſ. v. 3. 30. t. 5. Ait. Hort. Kew. ed. 2. v. 1. 232.—Receptacle globular, chaffy.—Native alſo of New South Wales. It flowers at Kew in July and Auguſt. This new ſpecies of *Opercularia* may poſſibly be a diſtinct genus; at leaſt ſuch a ſuſpicion is ſtarted by Dr. Young, who originally deſcribed it, and ſhould that opinion be eſtabliſhed, he propoſes to call it *Cryptoſpermum*. *Root* perennial, fibrous. *Stem* herbaceous, erect, three or four feet high, ſlightly quadrangular, ſmooth, rather ſtriated, branched. *Leaves* oppoſite, ſpreading, ſeſſile, acute, ſometimes pointed, green. *Stipulas* lateral, awl-ſhaped, greeniſh. *Flowers* aggregated, terminal, on longiſh ſtalks, which at firſt are erect, then drooping, and afterwards become erect again. The whole herb has rather a nauſeous ſmell, reſembling decaying pot-herbs.

4. O. *diphylla*. Willd. n. 3. (Rubioides diphylla; Soland. MSS.)—Flowers capitate. Calyx hiſpid.—Native of New Zealand. Very ſimilar to the two firſt ſpecies in habit. Its head of flowers about half the ſize of that of *O. aſpera*.

OPERCULUM, a lid, is excluſively uſed for the finally deciduous covering of the capſules of Moſſes, ſee Musci; which is firmly united to their rim, concealing the ring and fringes, till the ſeeds are ripe. It is itſelf concealed by the *calyptra* or veil, whoſe point is, in a growing ſtate, firmly united with the ſummit or centre of the lid, both together performing, as it appears, the office of a ſtigma. The lid is always more or leſs convex, ſometimes hemiſpherical, with a central boſs, or *umbo*, but more frequently conical or awl-ſhaped, and then either ſtraight or curved. The ſurface is always ſmooth; the colour commonly a little different from that of the capſule. The lid is frequently as long as its capſule, but hardly ever longer. The differences in its ſhape afford excellent ſpecific diſtinctions, but not generic ones.

Operculum, in the *Hiſtory of Shell-fiſh*, denotes the cartilaginous cover with which nature has furniſhed the mouths of the univalve water-ſhells; for as to the land ones, they have only a viſcid liquor to ſupply the place of an operculum.

OPETOPEC, or Mumbacho, in *Geography*, a ſmall but beautiful and fertile iſland of Mexico, with a town of the ſame name, in the S. part of lake Nicaragua.

OPFFERSHAUSEN, a town of Germany, in the county of Henneberg; 7 miles N.W. of Meinungen.

OPHEIM, a town of Norway, in the province of Bergen; 45 miles N.E. of Bergen.

OPHERA, or Opher, in *Scripture Geography*, a town of Judea, in the tribe of Benjamin. Joſh. xviii. 20.

OPHIASIS. See Alopecia.

OPHICARDELON, in *Natural Hiſtory*, the name of a gem mentioned by Pliny, which, he ſays, was a black ſtone covered at top and bottom with white: this ſeems, without doubt, to have been the *camea* of our jewellers.

OPHICEPHALUS, in *Ichthyology*, a genus of fiſhes of

of the order Thoracici; the head is coated with diſſimilar ſcales; body elongated. There are two ſpecies deſcribed by Dr. Shaw.

Species.

PUNCTATUS. Pale beneath, with the head pierced by pores, and the body ſpeckled with black points. It is about ten inches long; the dorſal fin commencing at no great diſtance from the head, and continued nearly to the tail; it is of a moderate breadth, and of a duſky colour ſpotted with black; the anal fin is of a ſimilar ſhape and colour; the tail is rounded; the pectoral fins rounded, and of a moderate ſize; the ventral are ſmaller; the ſcales are rather large; thoſe on the head are diſſimilar; *viz.* on the upper part angular, as in ſnakes; on the ſides ovate or rounded; the lateral line nearly ſtraight. It is a native of India, inhabiting rivers and lakes, and is conſidered as a delicate and wholeſome food.

STRIATUS. The abdomen and fins ſtriated with duſky and whitiſh variegations. It is about twelve inches long. It is a native of India, inhabiting lakes, where it is frequently found much larger than the ſize juſt mentioned; it is in equal eſteem as a food with the former ſpecies, and has been recommended as a proper diet for convaleſcents.

OPHIDIUM, a genus of fiſhes of the order Apodes; the generic character is head nakediſh; teeth both in the jaws and palate; gill-membrane ſeven-rayed; body enſiform. There are four

Species.

* BARBATUM; Bearded Ophidium. Lower jaw with four cirri. It inhabits the Mediterranean and Adriatic ſeas, and is rarely found in the Britiſh; it is from twelve to fourteen inches long; is of a ſilvery-grey colour with linear ſpots; lateral line duſky. The head of this ſpecies is ſmall, without ſcales; the upper jaw is doubled in and longer than the lower; the lips are thick; the teeth are very ſmall; the eyes are covered with a common ſkin, the pupil is black, the iris is golden, with a tranſparent nictitant membrane; the tongue is ſmooth, narrow and ſhort; the back is convex and blueiſh; the lateral line is brown; the vent is nearer the head than the tail; pectoral fins ſmall, brown at the baſe and edged with cinereous, the reſt joined together, narrow, white and edged with black; the ſcales are irregularly placed and diſperſed over the body; they are ſometimes round, ſometimes nearly oval, larger near the head, and hardly diſtinguiſhable near the tail, adhering to the body by means of a thin tranſparent ſkin. It is often taken by nets in Provence and Languedoc, and is moſt common during the ſummer ſeaſon. It feeds on ſmaller fiſhes and crabs.

IMBERBE; Beardleſs Ophidium. Jaws without cirri; tail ſomewhat blunt. It inhabits European ſeas, particularly the Mediterranean. The dorſal, anal, and caudal fins are united.

VIRIDE; Green Ophidium. Jaws without cirri; the tail is a little pointed. It inhabits the deep parts of the Greenland ſeas; is a very rare fiſh, and is often found as large as a whiting; the body is long, compreſſed, green; fleſh eatable.

ACULEATUM; Prickly Ophidium. The generic character is, jaws acuminate. It is deſcribed by Dr. Shaw under the name of O. roſtratum, or ophidium with an extremely long ſharp-pointed ſnout. This is readily diſtinguiſhable from another deſcribed by the ſame author, called the O. maſtacembalus, by the very great elongation of the upper lip, which terminates in a ſharp, ſlender ſnout. The colour of this fiſh is rufous brown above, ſilvery on the ſides and beneath; the dorſal fin is variegated with oblique duſky ſtreaks, and is marked with from two to five round, black ſpots, each ſurrounded by a pale yellowiſh circle.

MASTACEMBALUS; Ophidium with ſharpiſh-pointed equal jaws. This, according to Dr. Shaw, was firſt deſcribed by Dr. Ruſſel in his Natural Hiſtory of Aleppo. It has ſo much the general appearance of an eel, that it is often taken as ſuch by Europeans reſident at Aleppo, and eaten by them for that fiſh. Its uſual length is from a foot to eighteen inches long; the eyes are ſmall, ſituated on each ſide at no great diſtance from the tip of the ſnout; the noſtrils are ſeated at ſome diſtance before the eyes; the whole body is covered with ſmall ſcales, like thoſe of an eel; the colour on the upper parts is a clouded variegation of whitiſh and rufous, the under parts being entirely white; it is principally taken in the river Kowick near Aleppo.

OPHIOBORUS, in *Natural Hiſtory*, a name given by the ancients to a ſpecies of carnivorous fly, which feeds on the bodies of beetles, or other flies, or on the fleſh of dead ſerpents. Its wings are of the colour of poliſhed braſs, whence it was alſo called by the Greeks *chalcomuia*, the *braſs-fly*.

OPHIOGLOSSUM, in *Botany*, from οφις, *a ſerpent*, and γλωσσα, *a tongue*, an ancient name, admirably adapted to the cryptogamic plant, for which Linnæus and all other writers have retained it. Adder's Tongue. Linn. Gen. 559. Schreb. 756. Willd. Sp. Pl. v. 5. 58. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1106. Ait. Hort. Kew. ed. 1. v. 3. 455. Juſſ. 14. Lamarck Dict. v. 4. 561. Illuſtr. t. 814. Tourn. t. 325. Swartz Syn. Fil. 169. Brown Prod. Nov. Holl. v. 1. 163. —Claſs and order, *Cryptogamia Filices*. Nat. Ord. *Filices Spicatæ*.

Eſſ. Ch. Capſules naked, united into a jointed two-ranked ſpike, each of one cell and two valves, burſting tranſverſely.

Obſ. From this genus are now, with the greateſt propriety, ſeparated ſeveral Linnæan ſpecies, which have a ſcale-like involucrum to each capſule, as well as a ſpurious ring. Theſe conſtitute the *Lygodium* of Swartz, *Ugena* of Cavanilles, and *Hydrogloſſum* of Willdenow. The *Ophioglоſſum ſcandens* and *flexuoſum* of Linnæus and other authors, beautiful climbing ferns, totally unlike in habit to every genuine *Ophioglоſſum*, are among them.

1. O. *vulgatum*. Common Adder's-Tongue. Linn. Sp. Pl. 1518. Engl. Bot. t. 108. Bolt. Fil. t. 3. Fl. Dan. t. 147. Hedw. Theor. 44. t. 4. f. 20—23. (Ophioglоſſum; Fuchſ. Hiſt. 577. Math. Valgr. 543. Camer. Epit. 364. Ger. em. 404.)—Spike from the ſtem. Leaf ovate, obtuſe, cloſely reticulated.—Native of moiſt meadows and paſtures in Europe and North America, producing its ſpike in May. *Root* perennial, of a few thick ſimple fibres. *Herb* not a ſpan high, green and ſmooth in every part, conſiſting of a ſimple round erect *ſtem*, bearing one ovate *leaf*, an inch and half long, which, as Willdenow juſtly obſerves, is reticulated with cloſe, not very obvious, veins. The *ſtem* is terminated by the lanceolate, narrow, compreſſed *ſpike*, which conſiſts of numerous *capſules*, full of minute chaffy ſeeds, and is ſometimes divided. The nature of the flowers, or impregnation, is perhaps as abſolutely in the dark as in any other known plant.

2. O. *ovatum*. Sw. n. 2. (O. ſimplex; Rumph. Amb. v. 6. 152. t. 68. f. 2.)—Spike from the ſtem. Leaf ovate, acute, coarſely reticulated.—Native of the iſle of Bourbon, near the Volcano; alſo of ſhady moiſt graſſy paſtures in Amboina, &c. Much like the laſt, with which moſt people have confounded it, but the above characters may perhaps be

 ſufficient

ſufficient to diſtinguiſh them. The point of the *leaf* however varies in acuteneſs.

3. O. *nudicaule*. Linn. Suppl. 443. Swartz Syn. 397. t. 4. f. 2. (O. luſitanicum; Thunb. Prodr. 171.)—Spike radical. Leaf ovate, obtuſe, ſomewhat ſtalked.—Gathered by Thunberg at the Cape of Good Hope. About half the ſize of the two preceding, with a narrower *leaf*, whoſe *ſtalk* is ſcarcely connected with that of the *ſpike*.

4. O. *luſitanicum*. Linn. Sp. Pl. 1518. Lamarck Illuſtr. t. 864. f. 3. (O. anguſtifolium minimum; Barr. Ic. t. 252. f. 2.)—Spike from the ſtem. Leaf lanceolate.—Native of Portugal, Italy, &c. Size of the laſt, but differing eſſentially in the above characters. The *root* creeps, throwing up, here and there, a cluſter of *fronds*.

5. O. *gramineum*. Willd. in Act. Erford. for 1802. 18. t. 1. f. 1.—Spike from the ſtem. Leaf linear-lanceolate, acute, ribleſs.—Gathered by Koenig, in ſtony paſtures on the coaſt of Malabar, in New Holland, by ſir Joſ. Banks. More diminutive than any of the foregoing, being only two inches high, and very ſlender. The *ſpike* is ſcarcely ſurmounted by any point, or barren termination, which moſt of the former have.

6. O. *coſtatum*. Brown n. 2.—Spike from the ſtem. Leaf lanceolate-oblong, ſingle-ribbed, reticulated with veins.—Gathered by Mr. Brown at Port Jackſon, as well as in the tropical part of New Holland. We know it from his publication only.

7. O. *bulboſum*. Michaux Boreali-Amer. v. 2. 276. (O. crotalophoroides; Watt. Carol. 256?)—Spike from the ſtem. Leaf ovate, ſomewhat heart-ſhaped, obtuſe. Root bulbous.—Native of ſandy ground in South Carolina. Rather larger than *O. luſitanicum*; remarkable for its globoſe bulbous *root*. The *ſpike* is pointed.

8. O. *reticulatum*. Linn. Sp. Pl. 1518. Lamarck Illuſtr. t. 864. f. 2. (O. cordatum et reticulatum; Plum. Fil. 141. t. 164.)—Native of the Eaſt and Weſt Indies, not uncommon. This is larger than the *vulgatum*, and readily known by its broad heart-ſhaped, wavy *leaf*, ſtrongly reticulated with numerous veins.

9. O. *pendulum*. Linn. Sp. Pl. 1518. (Scolopendria major; Rumph. Amboin. v. 6. 84. t. 37. f. 3.)—Spike ſtalked, from near the middle of the long linear frond.—Native of woods in Amboina and the iſland of Mauritius, hanging from the branches of old trees. It was alſo found by the late Mr. David Nelſon, on the lofty mountains of Owhyhee, as appears by fine ſpecimens in the Bankſian herbarium. The *roots* conſiſt of long ſmooth fibres, like thoſe of an *Epidendrum* or *Dendrobium*. *Fronds* ſeveral, pendulous, twelve or eighteen inches long, linear, ſtrap-like, ſmooth, entire, tapering at each end, rarely cloven. *Spike* nearer the baſe than the extremity of the centre of each frond, ſolitary, ſtalked, two or three inches long, compoſed of very numerous crowded *capſules*, and generally tipped with a ſmall point.

10. O. *palmatum*. Linn. Sp. Pl. 1518. Plum. Fil. 139. t. 163.—Spikes ſeveral, lateral, ſtalked, from the wedge-ſhaped baſe of the palmate frond.—Native of Hiſpaniola, where it was found, in one ſpot only, by Plumier. We have ſpecimens from more recent French travellers. This is the largeſt known ſpecies of its genus. The fibres of the *root* are divided. *Fronds* erect, ſmooth, two feet high, each with a round *ſtalk*, a little hairy at its baſe; the *leaf* wedge-ſhaped at the lower part, where, from its edges, ſpring on each ſide three or four ſtalked drooping *ſpikes*, like thoſe of *O. pendulum*, except in being marginal. The upper part is deeply palmate, ſcarcely ribbed or veined, wavy, but entire.

OPHIOMANCY, Οφιομαντεια, compounded of οφις, *a ſerpent*, and μαντεια, *divination*, in *Antiquity*, the art of making predictions from ſerpents. Thus Calchas, on ſeeing a ſerpent devour eight ſparrows with their dam, foretold the duration of the ſiege of Troy. And the ſeven quoils of a ſerpent that was ſeen on Anchiſes's tomb, were interpreted to mean the ſeven years that Æneas wandered from place to place before he arrived in Latium. Thus, Virgil, Æn. lib. v. ver. 85.

"Septem enim gyros, ſeptena volumina traxit."

OPHIOMORPHITES, in *Natural Hiſtory*, the name given by ſome authors to the foſſils called more uſually cornu ammonis; which are compoſed of ſeveral wreaths, rolled in a ſpiral form over one another, and reſemble a ſnake when rolled up. Theſe are found of prodigious ſizes, ſome not leſs than the fore-wheel of a chariot. They are evidently formed from ſome ſea-ſhell, the ſhelly matter remaining on ſome of them, and all being compoſed of ſeveral cells, communicating with one another by means of a ſiphunculus, in the manner of thoſe of the nautilus.

OPHIOPHAGI, a name given by ſome to the eagle, vulture, and ſome other birds of prey which are ſometimes ſeen to feed on ſerpents.

Pliny gives the name ophiophagi to a certain people of Æthiopia, whom he deſcribes as very barbarous and ſavage, going always naked, and feeding on ſerpents, whence the appellation. Solinus, who generally copies Pliny but imperfectly, has perverted his meaning ſtrangely in this paſſage, having placed the ophiophagi in Arabia Felix, inſtead of Æthiopia.

OPHIORRHIZA, in *Botany*, a Linnæan genus, whoſe name is derived from οφις, *a ſerpent*, and ῥιζα, *a root*, becauſe the plant, ſays Hermann, is regarded in Ceylon as a grand ſpecific for the bite of the Nagha, or Ribband Snake. This genus was originally called *Mitreola* by Linnæus, being the *Mitra* of Houſton. (See MITREOLA.) Linn. Fl. Zeylan. 190, and 239. Gen. 85. Schreb. 111. Willd. Sp. Pl. v. 1. 826. Mart. Mill. Dict. v. 3. Michaux. Boreal-Amer. v. 1. 148. Juſſ. 143. Lamarck Dict. v. 4. 563. Illuſtr. t. 107. Gærtn. t. 55. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Stellatæ*, Linn. *Gentianæ*, Juſſ.

Gen. Ch. *Cal.* inferior, of one leaf, erect, compreſſed, five-toothed, equal, permanent. *Cor.* of one petal, funnel-ſhaped, tube inflated at the baſe; throat almoſt cloſed with hairs; limb five-cleft, obtuſe, ſpreading. *Stam.* Filaments five, thread-ſhaped, very ſhort, inſerted into the tube; anthers oblong, the length of the tube. *Piſt.* Germen ſuperior, cloven; ſtyle thread-ſhaped, as long as the ſtamens, thicker upwards; ſtigmas two, obtuſe. *Peric.* Capſule broad, rather obtuſe, divided into two, oblong, divaricated lobes, of two cells, burſting inwardly; the partition contrary. *Seeds* numerous, angulated, fixed round an oblong, ſtalked receptacle, looſe in the middle of each cell.

Eſſ. Ch. Corolla funnel-ſhaped. Germen cloven. Stigmas two. Capſule two-lobed.

1. O. *Mungos*. Linn. Sp. Pl. 213. Mat. Med. 59. t. 1. Plenck. t. 90.—Leaves lanceolate-ovate.—Native of the Eaſt Indies. *Stem* ſimple. *Leaves* oppoſite, ſtalked, entire, ſmooth, with obliquely tranſverſe nerves. *Flower-ſtalk* terminating the ſtem with a corymb of ſimple or cloven *ſpikes*, diſpoſed in an umbellate manner from one centre, and ſpreading. *Flowers* ſeſſile, from the upper ſide of the horizontal ſpike.

2. O. *Mitreola*. Linn. Sp. Pl. 213. Swartz. Obſ. 59. t. 3. f. 2. (Mitreola; Hort. Cliff. 492.)—Leaves ovate.—Native

—Native of damp, graſſy places, near the banks of rivers in Jamaica, flowering in the ſpring.—*Roots* from the lower joints of the ſtem, crowded, long, thread-ſhaped, white. *Stem* herbaceous, a foot high, ſimple or branched, erect, ſquare below, roundiſh above, rather weak. *Leaves* oppoſite, ſtalked, pointed, ſmooth on both ſides. *Flower-ſtalks* terminal, forked, lax. *Flowers* in ſpikes, ſeſſile, all turned one way, ſeparate, white; a ſolitary flower at the forked diviſion of the flower-ſtalk.

In Swartz's figure above quoted, the engraver by miſtake has ſubſtituted the wrong name for each of the plants delineated. Fig. 1. is *Macrocnemum jamaicenſe*, and fig. 2. is *Ophiorrhiza Mitreola*.

3. O. *ſubumbellata*. Willd. n. 3. Forſt. Prodr. Fl. Auſtr. n. 66.—Stem ſhrubby. Leaves lanceolate, acute. Umbels axillary, three-cleft.—Native of Otaheite.—This ſpecies is only known from the above quoted authors.

OPHIOXYLUM, Serpentine Wood, derived from οφις and ξυλον, becauſe its root ſpreads in a zigzag manner like the twiſting of a ſerpent. Linn. Fl. Zeylan. 188. Gen. 539. Schreb. 725. Willd. Sp. Pl. v. 4. 979. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 433. Juſſ. 149. Lamarck Dict. v. 4. 565. Illuſtr. t. 842. Gærtn. t. 109.—Claſs and order, *Polygamia Monoecia*, or rather *Pentandria Monogynia*. Nat. Ord. *Apocineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, five-cleft, ſometimes bifid, acute, erect, very ſmall. *Cor.* of one petal, funnel-ſhaped; tube long, thread-ſhaped, thickened in the middle; limb five-cleft, ſpreading. Nectary uncertain, or only found in imperfect flowers, at the mouth of the corolla, cylindrical, entire. *Stam.* Filaments five, very ſhort, in the middle of the tube, ſometimes only two; anthers pointed. *Piſt.* Germen ſuperior, roundiſh; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma capitate. *Peric.* Berry twin, two-celled. *Seeds* ſolitary, roundiſh.

Eſſ. Ch. Calyx five-cleft. Corolla five-cleft, funnel-ſhaped. Stamens five. Piſtil one.

1. O. *ſerpentinum*. Three-leaved Ophioxylum. Linn. Sp. Pl. 1478. Jacq. Hort. Schoenbr. t. 389. Curt. Mag. t. 784. (Liguſtrum foliis ad ſingula internodia ternis; Burman. Zeylan. 141. t. 64.)—Native of the Eaſt Indies. It was cultivated at Hampton Court in 1690, and flowers in May and June. *Stem* erect, round, quite ſimple. *Leaves* generally in fours, ſtalked, lanceolato-ovate, pointed, ſmooth. *Flowers* glomerate, terminal, white with a red tube; occaſionally imperfect, when they have a nectary like that of *Narciſſus*. *Berry* large and fleſhy, two-lobed, of a brick red. Gærtner calls this ſpecies *trifoliatum*, and ſays that, although the deſcription given by Rumphius in his Herb. Amboin. v. 7. 30, belongs undoubtedly to this plant, yet that his figure muſt be another ſpecies, for that it has oppoſite, cruciate *leaves*, white *flowers* and black *berries*. Gærtner propoſes to call it *O. alba*, but his opinion ſeems founded in error. The *Lignum Colubrinum* is ſuppoſed to be the root of this plant. Its ſerpentine form perhaps gave it the reputation of curing the bites of ſnakes, which it hardly retains at preſent.

Ophioxylum, in *Gardening*, contains a plant of the ſhrubby climbing kind, of which the ſpecies is the ſcarlet-flowered ophioxylum (O. ſerpentinum.)

Method of Culture.—This may be raiſed by ſeeds, which ſhould be ſown in pots in the early ſpring and be plunged in a bark hot-bed, and when the plants have obtained ſome growth, removed into ſeparate pots and replunged in the bark hot-bed of the ſtove, where the plants muſt be conſtantly kept. It may likewiſe be increaſed by layers and cuttings, which ſhould be laid down or planted out at the ſame ſeaſon, and have the ſame ſort of management as thoſe procured from ſeeds.

Theſe are ornamental ſtove plants.

OPHIR, in *Sacred Geography*, the place from which Solomon procured the gold and other precious articles with which he enriched himſelf, and adorned the temple of Jeruſalem.

Concerning the part of the world in which Ophir was ſituated, there have been many and various opinions and conjectures; ſome of them extremely fanciful, not to ſay abſurd; and others ſupported and elucidated with no inconſiderable portion of ingenuity and learning: ſtill, however, the exact ſituation of this place is undetermined, though the opinion that it was ſomewhere either on the eaſtern or weſtern coaſt of Africa ſeems the moſt plauſible, and to obtain the ſanction of the moſt learned and well-informed writers, who have diſcuſſed or adverted to this point of ſacred geography.

Before proceeding to notice and explain the various hypotheſes reſpecting the ſituation of Ophir, it may be proper to collect the different paſſages in ſcripture in which it is mentioned.

1 Kings, ix. 26, 27, 28. And king Solomon made a navy of ſhips in Ezion-geber, which is beſide Eloth, on the ſhore of the Red ſea, in the land of Edom.

And Hiram ſent in the navy his ſervants, ſhipmen that had knowledge of the ſea, with the ſervants of Solomon.

And they came to Ophir, and fetched from thence gold, four hundred and twenty talents, and brought it to king Solomon.

1 Kings, x. 11. And the navy alſo of Hiram, that brought gold from Ophir, brought in from Ophir great plenty of almug-trees, and precious ſtones.

Verſe 22. For the king had at ſea a navy of Tharſhiſh with the navy of Hiram; once in three years came the navy of Tharſhiſh, bringing gold and ſilver, ivory, and apes, and peacocks.

2 Chron. viii. 17, 18. Then went Solomon to Ezion-geber, and to Eloth, at the ſea-ſide in the land of Edom.

And Huram ſent him by the hands of his ſervants ſhips, and ſervants that had knowledge of the ſea; and they went with the ſervants of Solomon to Ophir, and took thence four hundred and fifty talents of gold, and brought them to king Solomon.

Chap. ix. 10. And the ſervants alſo of Huram, and the ſervants of Solomon, which brought gold from Ophir, brought algum-trees, and precious ſtones.

Verſe 21. For the king's ſhips went to Tharſhiſh with the ſervants of Huram; every three years once came the ſhips of Tarſhiſh bringing gold and ſilver, ivory, and apes, and peacocks.

1 Kings, xxii. 48. Jehoſhaphat made ſhips of Tharſhiſh to go to Ophir for gold; but they went not; for the ſhips were broken at Ezion-geber.

2 Chron. xx. 35, 36, 37. And after this did Jehoſhaphat, king of Judah, join himſelf with Ahaziah, king of Iſrael, who did very wickedly.

And he joined himſelf with him to make ſhips to go to Tharſhiſh; and they made the ſhips in Ezion-geber.

Then Eliezer, the ſon of Dodavah of Mareſhaſh, propheſied againſt Jehoſhaphat, ſaying, becauſe thou haſt joined thyſelf with Ahaziah, the Lord hath broken thy works. And the ſhips were broken, that they were not able to go to Tharſhiſh.

The authors of the Ancient Univerſal Hiſtory conſider the various marks by which the ſcriptures ſeem to lead us to Ophir, as ſo palpable and ſtriking, that they are ſur-

priſed the diſcovery of its ſituation ſhould be ſo very difficult, and have given riſe to ſo much diſcuſſion and controverſy: theſe marks they thus claſs and enumerate: 1. That Moſes ſpeaks of Ophir, the ſon of Joktan, who went with his brethren, and dwelt from Meſha, toward Sephar, a mount of the Eaſt. (Gen. x. 29, 30.) 2. That the ſame fleet went both to Ophir and Tharſhiſh, and ſet out from Ezion-geber, a ſea-port near Eloth, in the land of Edom, upon the Red ſea. 3. That the voyage took them up three years. 4. That it brought gold, precious ſtones, ſpices, ivory, ebony, almug-wood, peacocks, and monkies. 5. That Ophir not only afforded the greateſt quantity of gold, but that it alſo exceeded all other gold in fineneſs and value. To theſe marks of the ſituation of Ophir, ſupplied by ſcripture, they add that, according to Eupolemus, an ancient author, quoted by Euſebius, the Urphe, or Ophir, from whence this gold was brought, was an iſland in the Red ſea; not that ſea, which is commonly underſtood by that appellation, which lies between Arabia and Egypt, but the great Southern ocean, which extends between India and Africa, and waſhes up to the coaſt of Arabia and Perſia, and which was called the Red ſea, from the colour which the perpendicular ſun-beams gave it in thoſe hot climates. Ancient Univerſal Hiſtory, vol. iv. p. 102. note R.

Now it appears to us, that in theſe obſervations there are ſeveral circumſtances taken for granted, which are by no means warranted by the authority of thoſe paſſages in ſcripture, which we have quoted, as containing all the information reſpecting Ophir which the holy writings afford us: and as all the hypotheſes reſpecting the ſituation of this place proceed on the truth of theſe circumſtances, it may be proper to examine into it with ſome degree of caution and attention.

In the firſt place, the paſſages in ſcripture by no means warrant the opinion, that the ſame veſſels which made a voyage to Ophir, at the ſame time went to Tharſhiſh; and that theſe two places lay nearly in the ſame direction, and therefore muſt be ſought for, either in the ſame, or an adjoining country; or, at leaſt, in the courſe of the voyage which the ſhips of Solomon and of Hiram made. An examination and compariſon of the paſſages from Kings and the Chronicles, which we have quoted, will ſufficiently prove that there is no foundation for this opinion: the utmoſt they can be ſaid to prove is, that Solomon ſent ſhips to Tharſhiſh as well as to Ophir; and the words in 1 Kings, x. 21: for the king had at ſea a navy of Tharſhiſh, with the navy of Hiram, ſeem to indicate that there were two diſtinct fleets ſent out on two diſtinct voyages. It may alſo be remarked, that if the ſame fleet went at the ſame time to Ophir and Tharſhiſh, the commodities brought from theſe places could not have been ſo clearly diſtinguiſhed as they are, nor would the fleet have been called, as it is excluſively, the navy of Tharſhiſh.

But, in the ſecond place, there ſeems good reaſon for doubting whether Solomon ſent ſhips to Tharſhiſh, or if he did, whether Tharſhiſh was not very near Judea, and merely a depôt for the merchandize of more diſtant countries, which was brought there by the veſſels of that place. This opinion, though attended with ſome difficulties, and oppoſed by ſome paſſages in ſcripture, is evidently and directly ſupported by other paſſages, and is more conſonant with what we know, from other ſources, reſpecting Tharſhiſh.

By the expreſſion employed 1 Kings, x. 22: for the king had at ſea a navy of Tharſhiſh, it is more reaſonable to underſtand that this navy was either hired from Tharſhiſh by Solomon, or was compoſed of ſhips built after the manner of the ſhips of that place, than that it was a fleet which had ſailed for Tharſhiſh: the firſt of theſe ſuppoſitions is ſupported by the context, the navy of Tharſhiſh being mentioned immediately in connection with the navy of Hiram, which ſeems to imply, that as the latter was lent to Solomon by that monarch, the former was procured from Tharſhiſh. The other idea, that by the navy of Tharſhiſh is meant, ſhips built after the manner of the ſhips of Tharſhiſh, is countenanced by the paſſage in 1 Kings, xxii. 48. Jehoſhaphat made ſhips of Tharſhiſh to go to Ophir for gold. At any rate, theſe paſſages are directly againſt the opinion, that Tharſhiſh was a very diſtant place, which was viſited by the ſhips of Solomon at the ſame time that they went to Ophir.

There are, however, two paſſages which favour the opinion that Solomon and Jehoſhaphat ſent ſhips to Tharſhiſh, though they by no means prove the great diſtance of this place, nor that it was viſited at the ſame time with Ophir. In the paſſage of Chronicles, which correſponds with 1 Kings, x. 22, the navy of Solomon, inſtead of being called the navy of Tharſhiſh, as in the latter paſſage, is ſaid to have gone to Tharſhiſh, with the ſervants of Huram: and in 2 Chron. xx. 36, which correſponds with 1 Kings, xxii. 48, Jehoſhaphat is ſaid to have joined himſelf with Ahaziah, king of Iſrael, to make ſhips to go to Tharſhiſh, and not, as in the paſſage of Kings, to make ſhips of Tharſhiſh to go to Ophir for gold.

As theſe paſſages ſeem not to accord very well together, and conſequently cannot be brought forward of themſelves abſolutely to determine whether Tharſhiſh were a diſtant country, viſited by Solomon's ſhips, at the ſame time that they made their voyage to Ophir; or whether Solomon merely hired veſſels from Tharſhiſh, a neighbouring city or territory, or built his own veſſels on the model uſed here, it will be neceſſary to examine other paſſages, in which Tharſhiſh is mentioned. It may fairly be inferred, that as the Tharſhiſh ſpoken of, in the paſſages already quoted, is not particularized by any epithet, or circumſtance, to diſtinguiſh it from the Tharſhiſh mentioned repeatedly in other parts of ſcripture, that it is the ſame place; certainly, if it had been a very diſtant and comparatively unknown place, it would have been ſo diſtinguiſhed from the Tharſhiſh that was familiar to the Jews.

Tharſhiſh was the ſon of Javan, and according to the opinion of Joſephus, his deſcendants firſt peopled Cilicia, whence the whole country, as well as the city of Tarſis, took its name. That this place was celebrated for its ſhips and commerce, and that it was viſited by the Jews, the following paſſages, beſides others, will ſufficiently prove. In the 27th chapter of Ezekiel, where the prophet foretells the deſtruction of Tyre, he expreſsly mentions Tharſhiſh as one of the places which traded with that city: ver. 12. Tharſhiſh was thy merchant, by reaſon of the multitude of all kinds of riches; ver. 25. The ſhips of Tharſhiſh did ſing of thee in thy market. And that this Tharſhiſh, thus celebrated for its ſhips and commerce, was at no great diſtance from Tyre, appears from the 23d chapter of Iſaiah, ver. 6. where the prophet is alſo foretelling the miſerable overthrow of Tyre, "Paſs ye over to Tharſhiſh; howl, ye inhabitants of the iſle." In the firſt verſe of the ſame chapter alſo, the connection and intercourſe of Tharſhiſh with Tyre is pointed out, in theſe words, "Howl, ye ſhips of Tharſhiſh, for it (Tyre) is laid waſte." But the vicinity of Tharſhiſh, and the intercourſe with it, are ſtill more clearly pointed out in the ſecond verſe of the firſt chapter of Jonah; "But Jonah roſe up to flee unto Tharſhiſh from

the preſence of the Lord, and went down to Joppa; and he found a ſhip going to Tharſhiſh: ſo he paid the fare thereof, and went down into it, to go with them unto Tharſhiſh, from the preſence of the Lord."

It ſeems, therefore, fair to conclude, that the Tharſhiſh mentioned in the paſſages cited from Kings and the Chronicles, is the ſame place, known under that name, in other parts of ſcripture: it evidently was a place of great commerce, and famous for its ſhips; and though it may be granted that Solomon and Jehoſhaphat traded with Tharſhiſh, and did not merely hire veſſels from the merchants there, or build them after the models of that place, (though, as we have ſeen, there are paſſages in ſcripture which countenance theſe opinions), yet there is certainly no evidence that the fleet which viſited Ophir, at the ſame time viſited Tharſhiſh, or that the voyage to theſe places lay in the ſame track.

In the laſt place, the marks reſpecting the ſituation of Ophir, drawn from the ſuppoſed length of the voyage, are equally unſupported by the paſſages quoted from ſcripture. Even allowing that the navy of Solomon was three years on its voyage to Tharſhiſh, this circumſtance would not ſerve as a guide to aſcertain the poſition of Ophir, unleſs it had been proved that the voyage to the two places was performed at the ſame time; and we have ſhewn that there is no ground for this opinion. But as the alleged length of the voyage to Tharſhiſh may ſeem to militate againſt the idea, which we have thrown out, that this place was in Cilicia, and that, if reſorted to by Solomon's ſhips, it was reſorted to only as a depôt for merchandize, not as the native country of the commodities brought from it, it will be proper to examine on what authority it has been ſo generally maintained, or rather taken for granted, that the voyage to Tharſhiſh occupied the ſpace of three years. The paſſages have been already given, but it will not be amiſs to quote them again. 1 Kings, x. 22: for the king had at ſea a navy of Tharſhiſh with the navy of Hiram: once in three years came the navy of Tharſhiſh, bringing gold and ſilver, ivory, and apes, and peacocks. 2 Chron. ix. 21: for the king's ſhips went to Tharſhiſh with the ſervants of Huram; every three years once came the ſhips of Tharſhiſh, bringing gold and ſilver, ivory, and apes, and peacocks. Now, certainly, to read theſe paſſages with the eye of common ſenſe, without attachment to, or knowledge of, any hypotheſis on the ſubject, the ſum of the inferences that could reaſonably be drawn from them would ſimply amount to this; that Solomon had a ſupply of the commodities mentioned in them, once in three years; there is no aſſertion made, no intimation given, no reaſon ſupplied for drawing the inference, that the voyage to Tharſhiſh occupied three years. This interpretation of theſe paſſages, ſo plain, obvious, and conſiſtent in itſelf, muſt derive conſiderable ſupport from the facts, that Tharſhiſh is frequently mentioned in other parts of ſcripture, as at a ſhort diſtance from Judea, as famous for its ſhipping and commerce, and as having kept up a direct and frequent intercourſe with Joppa, one of the principal ſea-ports of Hiram, from whom Solomon received one of his fleets, or at leaſt, ſeamen to navigate it on its voyage to Ophir. The general concluſions, therefore, which we ſhould be diſpoſed to draw, are, that whatever may have been the diſtance and ſituation of Ophir, they ought not to be ſought after on the idea that this place and Tharſhiſh lay in the ſame route, and were viſited on the ſame voyage; nor that the voyage occupied ſo long a period as three years; and that, in order to procure gold and the other commodities enumerated in the paſſages cited, Solomon ſent directly to Ophir, in his own ſhips, in thoſe of his friend and ally, Hiram, king of Tyre, or in the ſhips of Tharſhiſh, which he probably procured through Hiram, who had regular and extenſive commercial intercourſe with that place; while, at the ſame time, Solomon traded directly with Tharſhiſh, one of the principal depôts for the merchandize in the Mediterranean.

Having thus thrown out our own ideas on one point of this queſtion, we ſhould now proceed to ſtate the various hypotheſes reſpecting the ſituation of Ophir; all of which it will be ſeen proceed on the aſſumptions, that Tharſhiſh lay on the ſame route with it, was viſited at the ſame time, and that the voyage occupied a ſpace of three years: but it may be proper to premiſe ſome miſcellaneous obſervations, which will clear the way for the more accurate and ſatisfactory ſtatement of theſe hypotheſes.

Ophir muſt have been viſited long before the time of Solomon; ſince the gold of Ophir is particularly mentioned in the book of Job, chapter xxii. verſe 24. "Then ſhalt thou lay up gold as duſt, and the gold of Ophir as the ſtones of the brooks;" or, as it is otherwiſe tranſlated, "Then ſhalt thou lay up gold as duſt, and wealth as in the brooks of Ophir," and in the 45th Pſalm, verſe 9, "Kings' daughters were among thy honourable women: upon thy right hand did ſtand the queen in gold of Ophir." That the gold of Ophir was in great plenty in Judea, in king David's time, appears from this circumſtance, that he left 3000 talents of it for the ſervice of the temple, beſides the 5000 talents which the princes of the people offered for the ſame purpoſe. (1 Chronicles, xxix. 4, &c.) And, as the authors of the Ancient Univerſal Hiſtory remark, we can hardly believe, that either David or the princes gave more than a certain proportion of it; ſuppoſing that it was a third part of all they poſſeſſed, there muſt have been at leaſt 24,000 talents of that metal in the kingdom. On this head, it may be remarked, that the Talmud reckons ſeven kinds of gold, of which the gold of Ophir was the moſt celebrated, and the moſt abundant. Tract. Joma, fol. xliv. p. 2.

Although the ſituation of Ezion-geber ſeems plainly and ſatisfactorily pointed out, yet ſome authors are of opinion, that it was not a port on the Red ſea, but on the Mediterranean: this opinion they ſeem to have embraced, in order to avoid the difficulty which puzzled Huet, and which led him to maintain, that the canal of communication between the Red ſea and the Mediterranean was opened in king David's time. It is certain, that in the time of Solomon there was ſome mode of communication, by means of ſhips, between Ezion-geber and the Mediterranean; for even allowing that Tarſhiſh was on the eaſt coaſt of Africa, and, therefore, could be reached by veſſels from the Red ſea, without the neceſſity of going round Africa, yet it is not eaſy to imagine by what means Hiram ſent the veſſels, with which he accommodated Solomon, from Phœnicia to the Red ſea, unleſs we ſuppoſe, with Huet, that there was at that time a canal between the two ſeas. (2 Chron. viii. 18.) But whatever difficulty there may be in finding a paſſage from Ezion-geber to the Mediterranean, that place cannot have been ſituated any where, except on the Red ſea, as there is not a ſingle paſſage in ſcripture in which Yam ſuph ſignifies the Mediterranean, or any other but the Red ſea. Indeed, there is good reaſon for believing that by Yam ſuph, the Heeropolitan gulf, or upper part of the Red ſea, was particularly deſignated. (Ancient Univerſal Hiſtory, vol. xviii. p. 366. note M.) Beſides, Ezion-geber is expreſsly ſaid to have been near Eloth, and this city is always placed on the Red ſea.

The almug-trees, which were part of the cargo brought from

from Ophir, are called by the rabbins coral wood, and are ſaid to have reſembled coral in hardneſs, colour, and poliſh; by Lemery, it is ſaid to have been a ſpecies of wood which he calls grenadille.

The firſt hypotheſis reſpecting the ſcite of Ophir, which we ſhall notice, places it in Peru; this opinion is maintained by the rabbi David Ganz, and by ſeveral other authors, mentioned in the Ancient Univerſal Hiſtory, vol. iv. p. 102. n. R. The grounds on which this opinion is reſted are extremely fanciful, independently of the extreme improbability, that in the time of Solomon any knowledge exiſted of America, much leſs any intercourſe with it. The gold of Ophir ſeems, 2 Chron. iii. 6. to be called the gold of Parvâim; for ſpeaking of the ornaments of the temple, which in other places are ſaid to have been of the gold of Ophir, Solomon, in this paſſage, is ſaid to have garniſhed the houſe with precious ſtones for beauty, and the gold was the gold of Parvaim. On this idea, that the gold of Ophir and of Parvaim were the ſame, and that, conſequently, theſe were two names for the ſame place, the opinion that Ophir was in Peru has been principally founded; Parvaim being ſuppoſed to bear ſome reſemblance in ſound, and in letters, to Peru. It is hardly neceſſary to expoſe the abſurd futility of this fancied reſemblance. Another mode of ſupporting this hypotheſis is equally ridiculous, *viz.* that the Hebrew word Ophir, and Peru expreſſed in Hebrew letters, are compoſed of the ſame letters, though differently arranged. On this hypotheſis it is not worth while to waſte any more time, except merely to remark, that according to ſir Walter Raleigh, Peru is not the true name of that country, but was given it by the Spaniards, in conſequence of their miſtaking the anſwer of the natives to a queſtion they did not underſtand: the Spaniards aſking them what country, the Indians anſwered Peru, or Beru, what do you ſay; hence the Spaniards concluded, that Peru was the name of the country.

Joſephus and others, having obſerved that the ſhips ſailed from the Red ſea, place Ophir in the Indian ocean, and ſuppoſe it to be the ancient Taprobana, or the Cherſoneſus Aurea, the land of gold. If it were Taprobana, it muſt have been the iſland of Ceylon, for there is good reaſon for ſuppoſing, that that iſland was known to the ancients by the name of Taprobana. The Aurea Cherſoneſus probably was the peninſula of Malacca. But there are ſeveral weighty objections to this hypotheſis: in the firſt place, the name of Ophir has no affinity to any of theſe iſlands, though Parvaim is ſuppoſed to reſemble Taprobana in ſound; a ſuppoſition which only ſhews on what ſlender grounds hypotheſes are frequently built. But in the ſecond place, if Ophir had been ſituated any where on the Indian ſeas, the gold and merchandiſe for which it was famous would not have been brought by ſea, but by caravans, by means of which all the Aſiatic commodities were introduced into the countries bordering on the Mediterranean, before the diſcovery of the Cape of Good Hope.

The authors of the Ancient Univerſal Hiſtory are diſpoſed to place Ophir "in ſome of thoſe remote rich countries in India, beyond the Ganges, and perhaps as far as China or Japan, which laſt ſtill abounds with the fineſt gold, and with ſeveral other commodities in which Solomon's fleet dealt, as ſilver, precious ſtones, ebony, and other valuable ſorts of wood, to ſay nothing of ſpices, peacocks, parrots, apes, and other ſuch creatures; and by its diſtance, beſt anſwers to the length of the voyage." (Ancient Univerſal Hiſtory, loc. cit.) But the objections already urged againſt the laſt hypotheſis, lie with equal weight againſt this opinion: it is not likely, that in Solomon's time ſuch a diſtant voyage could have been undertaken, in the courſe of which, the only ſecure and uſual manner of navigation practiſed among the ancients, *viz.* ſailing along the coaſt, could not here have been practiſed; and long before the period and direction of the monſoons, which in after ages were taken advantage of in order to ſail acroſs from the Red ſea to the coaſt of Malabar, were aſcertained. If the commodities obtained by Solomon actually came from the diſtant parts of India, they muſt, as has been already obſerved, have been brought by caravans. The paſſage in Geneſis has been already mentioned, in which Moſes informs us, that the habitation of Joktan's ſons was from Meſha, as thou goeſt unto Sephar, a mount of the eaſt. As Ophir was one of Joktan's ſons, a hypotheſis reſpecting the ſituation of Ophir has been built on this paſſage; this hypotheſis is principally ſupported by Calmet; he ſuppoſes it was placed ſomewhere towards Armenia and Media, where the Tigris and Euphrates take their riſe; and theſe rivers, he thinks, might have been ſubſervient to the commerce which was carried on. Calmet argues in favour and ſupport of this hypotheſis with conſiderable ingenuity and learning; but it certainly does not reſt on any ſolid foundation. If Ophir were ſituated near the riſe of the Tigris or Euphrates, the veſſels of Solomon could hardly have reached it; and if the merchandiſe were brought down to the ſhips at the mouth of theſe rivers, it would not have been ſaid that they ſailed to Ophir. As the commonly received opinion, that the voyage to Ophir occupied a ſpace of three years, militates againſt the hypotheſis, that it was ſituated ſo near to Judea, as Armenia or Media, Calmet ſuppoſes, that the three years mentioned in the text might mean only three ſummers, and two winters, or thirty months.

Dean Prideaux offers his conjectures, on the ſuppoſition, that it was the voyage to Tharſhiſh only, and not the voyage to Ophir, or to Ophir and Tharſhiſh together, which took up three years going and coming; hence he concludes, that Ophir might be much nearer Judea than Tharſhiſh, and that the voyage to it might have been performed in a much ſhorter ſpace of time than three years, if they had not been obliged to go to Tharſhiſh for ſome commodities, with which Ophir could not ſupply them; hence he infers, that any place in the Great Indian ſea, at the diſtance of three years' voyage, which yielded gold, ſilver, ivory, apes, and peacocks, might be the Tharſhiſh; and any other, though much nearer, where they could have gold, almug-trees, and precious ſtones, might be the Ophir mentioned by the ſcriptures; and he attempts to ſhew, that the ſouthern part of Arabia produced the greateſt quantities of the beſt gold, and, conſequently, might be the land of Ophir. Againſt this hypotheſis, the objection already ſtated lies with great force. As a conſtant commercial intercourſe was kept up between India and the more diſtant parts of Aſia, and the countries on the Mediterranean, by means of caravans, it is by no means probable, that veſſels could be employed for this purpoſe; hence, wherever Ophir may have been ſituated, it ought not to be ſought for in the Indian ocean, or in any part of Aſia.

Againſt this opinion of dean Prideaux, the remarks of the authors of the Ancient Univerſal Hiſtory alſo ſtrongly militate. "Though it be granted (they obſerve) that Tharſhiſh and Ophir might be diſtinct places, and at ſome conſiderable diſtance from each other; yet, if the latter had been ſo nigh as South Arabia, and had yielded ſuch plenty of the fineſt gold, almug-trees, and precious ſtones, it is ſcarcely probable, that they would have gone ſo much farther for ſuch inferior trifles as ſilver, ivory, monkies, and peacocks; it is more likely that they went fartheſt for the fine gold, pre-

cious

cious ſtones, and things of the greateſt value." Ancient Univerſal Hiſtory, vol. iv. p. 105. note R.

Having thus conſidered the various hypotheſes, which proceed on the idea, that Ophir was ſituated either in South America, or the continent of Aſia, or in ſome of the Aſiatic iſlands, and proved how little foundation there is for any of them, even on the ſuppoſition that Ophir and Tharſhiſh were viſited on the ſame voyage; that Tharſhiſh was not the Tharſhiſh of Cilicia, but a much more diſtant and leſs known place; and that the ſpace of three years was occupied in the voyage to Ophir and Tharſhiſh; we ſhall now proceed to ſtate, and conſider that claſs of hypotheſes, which look for theſe places either in Africa alone, or in Africa and Europe.

The opinion that Ophir was Sofala, a territory or town of Africa, oppoſite to the iſland of Madagaſcar, has been long held, as we learn from Bochart (lib. ii. cap. 27. p. 160.) Sofala is thought by Moquet to be the Sopheira of the Septuagint, and he grounds his opinion on the fact, that liquids are often put for one another, ſo that Sopheira and Sofala might be uſed indiſcriminately as the name of the ſame place. Lopez, in his Indian Voyage relates, that the inhabitants of the country near Madagaſcar, boaſt that they have books which prove, that in the time of king Solomon the Iſraelites made a voyage thither every third year to fetch gold. In the Mélanges de Geographie et d'Hiſtoire naturelle, par Zein-eddin Omar, fils d'About Modhaffer, ſurnommè Ebn al-ouardi, ecrivain du xiii ſiècle, of which an account is given in Notices des MSS. du Roi, tom. xi. p. 40, Sophala is called Sophala eddhabab, or the Golden Sofala. This opinion is ſtrongly and learnedly ſupported by D'Anville, in his Diſſertation ſur la Pays d'Ophir, publiſhed in the Memoires de Literature, tom. xxx. p. 83, &c. But it has received the moſt ample and elaborate elucidation by Bruce, in the ſecond book of his Travels, c. 4, who ſeems to have convinced Dr. Robertſon, (Hiſtorical Diſquiſition concerning India, p. 10.) It will, therefore, be proper to conſider this hypotheſis, as ſupported and elucidated by Bruce, at ſome length.

He commences his inveſtigations and reaſonings on this ſubject, by laying down three poſitions; 1ſt. That the trade to Ophir was carried on from the Elanitic gulf, through the Indian ocean; 2dly. That gold, ſilver, and ivory, but principally ſilver, were the commodities obtained by this trade; and 3dly. That the time occupied in this voyage in going to Ophir, and returning from it, was preciſely three years.

The great difficulty with Mr. Bruce ariſes from the ſuppoſed length of the voyage; for it does not ſeem probable, that three years would be conſumed in going from the Red ſea to the Mozambique channel, and in returning to Eziongeber, even in the imperfect ſtate of navigation in Solomon's time. In order to obviate this difficulty, Mr. Bruce has recourſe to the obſtacles to the voyage, which the monſoons of the Arabian gulf would throw in the way of theſe inexperienced navigators. Before proceeding to point out how the monſoons would lengthen the voyage exactly to the period of three years, he adduces ſome collateral arguments to prove that Sofala was famous for its gold mines. According to John Dos Santos in 1568, he ſailed up the river Cuama, as far as Tete; from this place, he penetrated nearly 200 miles into the interior of the country, where he ſaw gold mines working at a place called *Afura;* ſtill farther up the country, he underſtood that the ſilver mines of Chicoua were ſituated: at both places there were appearances of the mines having been wrought for a long ſeries of years, and large remains of maſſy buildings.

Mr. Bruce ſuppoſes, that the fleet of Solomon left Eziongeber in the month of June; at this ſeaſon of the year the northern monſoon prevails, which would carry the ſhips as far as Mocha; at this place, the courſe of the gulf changing, though the monſoon continued to blow in the ſame direction, it would be no longer favourable for the proſecution of the voyage. The fleet, therefore, he ſuppoſes, would anchor in the harbour of Mocha. In the month of Auguſt it would be again able to proceed, and clear the ſtraits of Babelmandeb. After this, its courſe was nearly ſouth-weſt; and as at cape Gardefan the wind at this time of the year blows from that quarter, the fleet would be obliged to anchor under the cape, or in a port near it, which was afterwards called Promontorium Aromatium. Here it was detained till the month of November, but during this ſtay, Mr. Bruce ſuppoſes, that ivory, frankincenſe, and myrrh were purchaſed, as part of the cargo, for which the fleet was ſent out. In the month of November the wind changes to north-eaſt, and as this was extremely favourable to the fleet, the courſe of which was ſtill ſouth-weſt, it again proceeded on its voyage, which would have ſoon been completed, but off Melinda, towards the beginning of the following month, an irregular monſoon ſets in from the ſouth-weſt, and, conſequently, directly in the teeth of the ſhips. This change in the wind compelled the ſeamen to put into port; and at this place, near Melinda, a city or diſtrict is ſituated, called Tarſhiſh; this Mr. Bruce conſiders as a ſtrong corroboration of the accuracy and truth of this opinion, both with reſpect to the ſituation of Ophir, and with reſpect to the time and courſe of the voyage thither. But the evidence on which this author endeavours to prove, that a place called Tharſhiſh or Tarſhiſh was ſituated near Melinda, appears to us very ſlight and inconcluſive. The Annals of Abyſſinia mention, that Amda Icon, making war on that coaſt in the 14th century, gives a liſt of the rebellious Mooriſh vaſſals, and the chief of Tarſhiſh is particularly noticed, in the very place where Mr. Bruce places that city or diſtrict. But it is hardly juſt to infer the name of a place in Solomon's time, from the name which it bore in the 14th century, beſides the probability, that, as this Tarſhiſh was governed by a Mooriſh chief, the name was given it by that nation, from the place whence they derived their origin. At this place, which Mr. Bruce ſuppoſes to have been Tarſhiſh, the fleet were obliged to ſtay till the month of April of the ſecond year; at the end of that month, or towards the beginning of May, the wind comes round to the north-eaſt, and as the diſtance to Sofala was now very trifling, the fleet probably reached its ultimate deſtination the ſame month that it left Tarſhiſh. As the north-eaſt monſoon continues from May till October, the fleet would be detained all this time at Sofala; in the beginning of November, the ſouth-weſt monſoon ſets in, and with this it ſails on its return to the Red ſea. This monſoon, Mr. Bruce ſuppoſes, would carry it as far as Melinda or Tarſhiſh, when the north-eaſt monſoon would again meet it, and would oblige it to put into port, and remain there till the ſouth-weſt wind ſprung up in the month of May, of the third year of its voyage. This wind would continue till the fleet arrived within the ſtraits at Mocha, where it would be again detained by the ſummer monſoon, blowing directly in its teeth from Suez. In October or November, the adverſe northerly monſoon gives way to a ſouth-eaſt wind, which would carry it up into the Elanitic gulf, towards the end of December of the third year.

Setting aſide all objections to this ingenious mode of explaining and defending his hypotheſis, founded on the opinion, which we have already repeatedly ſtated, that there is no evidence that Tarſhiſh was viſited during the voyage to Ophir, or that the voyage occupied three years, it is too obvious,

obvious, that Mr. Bruce has accommodated the circumſtances and duration of this ſuppoſed voyage to his preconceived notions; and after all the duration cannot properly be ſaid to have been three years, as the fleet is ſuppoſed to have left Ezion-geber in the ſummer, and to have returned in the December of the third year; beſides, if the account of the direction and period of the monſoons, as given by Mr. Bruce, when the fleet was outward bound, be compared with the account of their direction and continuance, when it was homeward bound, they will not be found to accurately agree.

The laſt hypotheſis which we ſhall notice, ſuppoſes that the fleet of Solomon, in its voyage to Ophir and Tarſhiſh, actually ſailed round the Cape of Good Hope, and came to Joppa, by the Mediterranean. This hypotheſis is ſupported by Huet: he thinks that Ophir was a general name for all the Oriental coaſt of Africa, particularly of the country of Sofala; in this reſpect agreeing with Bruce; and that Tarſhiſh was alſo a general name for all the occidental coaſt of Africa and Spain, and in particular of that coaſt in the neighbourhood of the mouth of the river Guadalquivir, a country fertile in mines of ſilver; he alſo maintains that the Cape of Good Hope was known, often frequented, and doubled in Solomon's time, and for many years afterwards. Hiſtory of Commerce and Navigation, p. 19, 20.

A writer in the Gentleman's Magazine (for 1786, p. 28.) coincides in opinion with Huet that the fleet of Solomon in its voyage doubled the Cape of Good Hope, and he places Ophir on the weſt coaſt of Africa; Guinea and Negroland he ſuppoſes to have been the places viſited by Solomon's fleet. In ſupport of this opinion, he offers, however, but weak and fantaſtical arguments. One of them is, that the Hebrew words, which ſignify *duſt* and *aſhes*, make up the etymon of Ophir; and as gold duſt principally is found in Guinea, and Eliphaz in his exhortation to Job, tells him he ſhall lay up gold as duſt, and the gold of Ophir as the ſtones of the brooks, he infers that Ophir is to be ſought for in Guinea: another of his proofs is drawn from the circumſtance that circumciſion is uſed among the negroes of the Gold Coaſt, which may have been introduced here by the Hebrews.

But the opinion that the fleet of Solomon, in its voyage to Ophir and Tarſhiſh, circumnavigated Africa, is moſt ſtrongly and ably ſupported by Dr. Doig, formerly maſter of the grammar ſchool at Stirling, and the author of the letters, addreſſed to lord Kames, on the Savage State.

He ſuppoſes that there were ſeveral places called Ophir; that the original Ophir, ſo named from the ſon of Joktan, was ſituated at no great diſtance from Judea, and that it was from this Ophir that the gold mentioned in Job was obtained. As the original Ophir abounded in gold, this name was applied to ſeveral other places, where that metal was found in great plenty; but that the Ophir of Solomon was not, as Mr. Bruce maintains, ſituated on the ſouth-eaſt coaſt of Africa, becauſe the fleet, in the very ſame voyage, touched at Tarſhiſh, which lay in a very different quarter.

In order, therefore, to aſcertain the ſcite of Ophir, Dr. Doig deems it neceſſary previouſly to fix the ſituation of Tarſhiſh: this name was alſo given to many places: the original Tarſhiſh was ſituated on the weſtern coaſt of Aſia Minor: but this original Tarſhiſh, Dr. Doig contends, was not the Tarſhiſh of Solomon. This place, according to him, was ſituated in Spain, in that part of it in which Huet places it; *viz.* in Spaniſh Bœtica, near the mouth of the Guadalquivir. It appears from Iſaiah and Ezekiel that the merchants of Tarſhiſh traded in the markets of Tyre with ſilver, iron, lead, and tin; and Jeremiah expreſsly ſays, "ſilver ſpread into plates is brought from Tarſhiſh:" but that part of Spain which lies on the river Guadalquivir, was famous among the ancients for its mines of ſilver. Beſides, the river Bœtis, which divides Bœtica, is called *Tarteſſus* by Ariſtotle, Strabo, and ſeveral other authors; and in this neighbourhood were a lake and city of the ſame name. Dr. Doig next proceeds to prove that Tarteſſus and Tarſhiſh are the very ſame name; the Phœnicians changing the *ſchin* into *thau*, made the latter word Tartiſh.

Having thus fixed the ſituation of Tarſhiſh, Dr. Doig next proceeds to aſcertain the poſition of Ophir. This he concludes to have been on the coaſt of Guinea. In reply to the objection, that the fleet of Solomon would not have gone ſo far as the weſt coaſt of Africa for gold, he replies that at this time no gold was to be found on the eaſtern coaſt: but his argument on this point evidently proceeds on taking for granted his own hypotheſis. If they had found gold (he obſerves) on any part of the eaſtern coaſt, they would have returned to Ezion-geber, and not proceeded round Africa, merely for the purpoſe of trading at Tarſhiſh, but as they did not find gold on this coaſt they were obliged to double the Cape, and then it was more eaſy to proceed home by Tarſhiſh, than by the route according to which they came. After having completed their cargo at this latter place, Dr. Doig ſuppoſes the fleet ſailed for Joppa; and that the next voyage was reverſed, *i. e.* they firſt viſited Tarſhiſh in Spain, then Guinea, and ſo doubled the Cape, and returned along the eaſtern coaſt of Africa, and up the Red ſea, to Ezion-geber.

Both Dr. Doig, and the writer in the Gentleman's Magazine, endeavour to ſupport their opinion, that the fleet of Solomon circumnavigated Africa, by the account which Herodotus gives of the voyage round the Cape of Good Hope, which was performed during the reign of Necho, king of Egypt. According to this hiſtorian, the fleet ſent out by that monarch was navigated by Phœnician mariners; it ſailed from a port in the Red ſea; it returned by the ſtraits of Gibraltar; and it was exactly three years in its voyage. The truth of this narration by Herodotus has been queſtioned; but in our opinion, without any ſolid reaſon; indeed the circumſtance, which he mentions with aſtoniſhment and ſome degree of incredulity, as having occurred during this voyage, *viz.* that in one part of the courſe the ſhadows fell on the right hand, is ſo unlikely to have been an invention of the mariners, ſo diſſimilar to all the marvellous ſtories related of diſtant countries in thoſe times, and yet ſo certainly true, that it alone proves that Africa had been circumnavigated, or at leaſt that the voyage had been proſecuted beyond the line. But, we imagine, a little reflection on this voyage which is mentioned by Herodotus, will convince us that it rather makes againſt, than for the truth of the opinion, that the Cape was doubled in Solomon's time. As the Phœnicians were employed by Solomon, it is natural to ſuppoſe that they had gone this voyage frequently before. Indeed, both Huet and Dr. Doig maintain that the circumnavigation of Africa had been often accompliſhed by the Phœnicians, before they were employed by Solomon. Now the voyage performed round Africa in the reign of Necho, which Herodotus mentions, took place two centuries after the time of Solomon. But Herodotus relates it as ſomething very extraordinary; indeed his manner would naturally lead to the ſuppoſition that ſuch a voyage had never been performed before: if it had been performed frequently before by the Phœnicians, it is not probable that the mariners, on their return from this voyage, would have particularly mentioned the circumſtance of their ſhadows falling on their right; nor would

Herodotus

Herodotus have been unwilling to credit it, if it had been confirmed by the teſtimony of thoſe who had performed the ſame voyage before. As, therefore, from the account of the hiſtorian, the voyage undertaken in the reign of Necho, two centuries after Solomon, was evidently no common event, we are juſtified in doubting, at leaſt, whether the fleet of the Jewiſh monarch circumnavigated Africa, and conſequently whether Ophir was ſituated on the weſt coaſt of that continent.

To conclude, if we are correct in the opinions we have advanced, that there is no evidence in ſcripture, that Ophir and Tarſhiſh were viſited during the ſame voyage; that the voyage to either, or both, actually took up three years; and that the Tarſhiſh of Solomon was a different place from the Tarſhiſh in Cilicia; it is evident that the inveſtigations hitherto made into the ſituation of theſe places, and into the courſe of the voyages performed by Solomon's fleet, proceed on unſupported data; and, conſequently, though ſome of them diſplay great ingenuity and learning, they can only lead us aſtray from the real object of our reſearch.

Ophir, in *Geography*, a mountain of Sumatra, ſituated immediately under the equinoctial line, and ſuppoſed to be the higheſt viſible from the ſea; its ſummit being elevated 13,842 feet above that level. The following is the reſult of obſervations made by Mr. Robert Nairne concerning the height of mount Ophir: height of the peak above the level of the ſea, in feet, 13842, Engliſh miles 2,6216, nautical miles 2,26325; inland, nearly, 26 nautical miles; diſtance from Maſſang point 32 nautical miles; diſtance at ſea before the peak is ſunk under the horizon, 125 nautical miles; latitude of the peak 0° 6′ N.; a volcano mountain, S. of Ophir, is ſhort of that in height by 1379 feet; inland, nearly, 29 nautical miles.

The idea of Sumatra being the country of Ophir, whither Solomon ſent his fleets, is too vague, ſays Mr. Marſden, and the ſubject wrapt in a veil of too remote antiquity to admit diſcuſſion. The name of Ophir was given to the mountain of Sumatra by the Europeans in modern days. Another near Malacca is alſo ſo named.

OPHIRA, in *Botany*, a genus of uncertain derivation. This plant was originally diſcovered by Burmann in Africa. Both Juſſieu and Schreber conſidered it as nearly allied to the *Grubbia* of Bergius; and Dr. Smith, upon examination, finds them to be one and the ſame plant. (See Grubbia.) Of courſe the original name remains.—Linn. Mant. 150. Schreb. 259. Willd. Sp. Pl. v. 2. 414. Mart. Mill. Dict. v. 3. Juſſ. 321. Lamarck Dict. v. 4. 565. Illuſtr. t. 293. —Claſs and order, *Octandria Monogynia*. Nat. Ord. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Involucrum of two lateral, kidney-ſhaped, emarginate, conduplicate, permanent valves, containing three flowers. *Cor.* ſuperior, of four, oblong, converging petals. *Stam.* Filaments eight, the length of the corolla; anthers ovate. *Piſt.* Germen inferior, turbinate, hiſpid, ſtyle thread-ſhaped, ſhorter than the ſtamens; ſtigma emarginate. *Peric.* Berry of one cell. *Seeds* two.

Eſſ. Ch. Calyx a two-valved involucrum, containing three flowers. Petals four, ſuperior. Berry of one cell.

1. O. *ſtricta*. Linn. Mant. 229. Lamarck Illuſtr. t. 293. —Native of Africa.—The *ſtems* of this little erect ſhrub are quadrangular, and greyiſh. *Leaves* oppoſite, linear or lanceolate, rather pointed, coriaceous, green above, ſilvery white beneath, on ſhort ſtalks. *Flowers* axillary, ſeſſile, lateral, oppoſite, capitate. *Berry* a little, oblong, very reſinous ſort of cone, ſomewhat like a minute ſtrawberry.

OPHITES, οφιτης, in *Natural Hiſtory*, a ſort of variegated marble of a duſky green ground, ſprinkled with ſpots of a lighter green; otherwiſe called *ſerpentine*.

It is thus called from the Greek, οφις, *ſerpent*; becauſe its ſpots reſemble thoſe of that animal.

The ancients knew three ſpecies of this kind, which they call the black, the white, and the grey ophites, and this laſt alſo frequently *tephria*; and allowing theſe ſpotted variegations to be the characters of an ophites, we have, beſide theſe, two others known at this time.

The other two ophitæ, which ſeem not to have been known to the ancients, are, 1. A greyiſh-brown one with green ſpots. It is frequent in Egypt and Arabia, and is ſaid to have been dug in England. 2. A pale grey one, with green ſpots and veins. It is very hard, and capable of an elegant poliſh. It is frequent in Germany, and tables are made of the large pieces and vaſes of the ſmaller ones. It is ſaid alſo to be found in England.

Ophites, in *Eccleſiaſtical Hiſtory*, is alſo the name of a ſect of ancient heretics, who ſprung out of the Gnoſtics, in the latter end of the ſecond century; ſo called from their worſhipping the ſerpent that ſeduced Eve.

This ſerpent, they taught, was inſtructed thoroughly in all knowledge; and they make it the father and author of all the ſciences. On which principle they founded a thouſand chimeras; part of which may be ſeen in St. Epiphanius. See Gnostic.

They ſaid this ſerpent was the Chriſt; that he was very different from Jeſus born of the Virgin, into whom, ſaid they, the Chriſt deſcended; and that it was this Jeſus, not the Chriſt, that ſuffered. Accordingly, they made all thoſe of their ſect renounce Jeſus to follow Chriſt.

In conſequence of this opinion, they nouriſhed a certain number of ſerpents, which they looked upon as ſacred, and to which they offered a ſubordinate kind of honour and worſhip.

The Sethians, or Sethites, mentioned by Theodoret, were either the ſame with the Ophites, or very little different from them.

The leader of this ridiculous ſect was one Euphrates; it had its origin among the Jews, and was of a more ancient date than the Chriſtian religion. A part of its followers embraced the Goſpel, while the other retained their primitive ſuperſtition; and from hence aroſe the diviſion of the Ophites into Chriſtian and Antichriſtian.

OPHIUCUS, in *Aſtronomy*, a conſtellation of the northern hemiſphere; called alſo Serpentarius. See Constellation and Serpentarius.

OPHIURUS, in *Botany*, ſo denominated from οφις, *a ſerpent*, and ουρα, *a tail*, becauſe of the ſlender-jointed ſtructure of the ſpike, is a genus of graſſes, founded by Gærtner, and publiſhed by his ſon, in the third volume of his work on fruit and ſeeds, p. 3. t. 181. f. 3. The two ſpecies there deſcribed are *Rottböllia incurvata* and *corymboſa* of Linnæus. Mr. Brown, Prodr. Nov. Holl. v. 1. 206, retains the latter only as conſtituting the genus in queſtion; referring the former, with ſome heſitation, to his own *Lepturus*, which is *Rottböllia repens* of Forſter's *Prodromus*, n. 151. *Ophiurus* ſeems to differ from *Lepturus* chiefly in having the glume of the calyx ſimple, or of one leaf, inſtead of two parallel ones, a diſtinction which appears to us, in this caſe, rather artificial.

OPHIUSA, or Ophinza, ſometimes called *Orphiſa*, in *Ancient Geography*, an iſland which ſome have confounded with the iſle of Fromentera, for an account of which ſee Pityuse *Iſlands*. The Ophiuſa was called by the Romans Colubraria, and the moderns have given it the name of Moncalobrer (Columbrates); it is ſituated on the coaſt of the kingdom of Valencia in Spain.

O P H

Ophiusa was alſo, according to Pliny, the ancient name of the iſland of Rhodes; and according to Steph. Byz. the name of Libya.—Alſo, a town placed by Strabo on the ſouthern bank of the river Tyras, 140 ſtadia from its mouth; it is now "Palenca."

OPHIUSSA, the ancient name of the iſle of Thenos, one of the Cyclades, according to Pliny.—Alſo, a ſmall iſland in the vicinity of the iſle of Crete, and near Hierapytna. Pliny.

OPHRINIUM, or Ophrynium, *Renn-Keui*, a town of Aſia Minor, in the Troade, near Dardanum or Dardanus and Rhætium. Here was a grove conſecrated to Hector. This town is mentioned by Herodotus, Strabo, and Xenophon, the laſt of whom ſays that the inhabitants ſacrificed hogs and burnt them entire.

OPHRYS, in *Botany*, from οφρυς, *the eye-brow*, owed that appellation, as we learn from Pliny, to its having been uſed for blackening the eye-brows. His deſcription, of the toothed leaves, does not however by any means accord with any *Ophrys* of modern botaniſts. Linn. Gen. 462. Schreb. 502. Willd. Sp. Pl. v. 4. 61. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 931. Brown Prodr. Nov. Holl. v. 1. 313. Swartz. Act. Holm. for 1800. 222. t. 3. f. D. Schrad. N. Journ. v. 1. 43. t. 1. f. D. Juſſ. 65. Lamarck Illuſtr. t. 727.—Claſs and order, *Gynandria Monandria*. Nat Ord. *Orchideæ*.

Gen. Ch. *Cal.* Perianth ſuperior, of three oblong, ſpreading, often coloured leaves. *Cor.* Petals two, oblong, ſmaller than the calyx. Nectary a large, convex, lobed, coloured lip. *Stam.* Filament none; anther terminating the ſtyle, of two cells in front, each containing one ſtalked maſs of pollen, proceeding from a diſtinct pouch at the baſe. *Piſt.* Germen inferior, oblong, twiſted; ſtyle ſhort, erect; ſtigma in front, convex, broad, below the anther. *Peric.* Capſule oblong, of one cell, with three ribs, burſting longitudinally between the ribs. *Seeds* very numerous, minute, roundiſh, each with a chaffy tunic.

Eſſ. Ch. Lip from the baſe of the ſtyle, ſpreading, convex, lobed, without a ſpur. Anther terminal, fixed to the ſtyle, of two cells. Maſſes of pollen ſolitary, ſtalked, from ſeparate pouches at the baſe.

Obſ. Swartz, and after him Willdenow, conſiders this genus as differing from *Orchis*, merely in the want of a ſpur. Mr. Brown has firſt, from the obſervations of Mr. Francis Bauer of Kew, detected a very curious character, by which the genuine ſpecies of *Ophrys*, reſembling the bodies of various inſects in the form and colours of their lips, and forming a moſt natural genus by themſelves, are kept ſeparate. This character conſiſts in the origin of the ſtalked maſſes of pollen, each from a ſeparate pouch or bag. In *Orchis* they both ſpring from a ſingle one; in *Habenaria*, to which *Orchis bifolia* belongs, there is no ſuch pouch at all at the baſe of the anther.

We have three of theſe plants wild in Britain, *O. muſcifera*, Engl. Bot. t. 64; *apifera*, t. 383; and *aranifera*, t. 65. They are found in chalky ground, the firſt and the laſt but rarely. The *apifera*, commonly called the Bee Orchis, is leſs unfrequent, and ſometimes abounds in dry gravelly paſtures, where it bloſſoms in July. Several exotic ſpecies have been adopted by Willdenow from Cavanilles and others; and ſome have been recently publiſhed by Deſfontaines, (from the drawings of Tournefort's plants in the Muſeum at Paris,) in the Annales du Muſeum d'Hiſtoire Naturelle, v. 10. We are not poſſeſſed of ſufficient materials at preſent to give a detailed hiſtory of the whole; becauſe we cannot confront the ſpecimens of the different authors who have laboured at this ſubject, and who ſeem, in ſome inſtances, to have deſcribed the ſame thing under different names.

Ophrys, in *Gardening*, compriſes plants of the bulbo-fibrous-rooted perennial kind, of which the ſpecies cultivated are; the common ophrys, or twayblade (O. ovata); the ſpiral ophrys, or triple ladies traces (O. ſpiralis); the bird's neſt ophrys (O. nidus-avis); the fly ophrys (O. muſcifera); the bee ophrys (O. apifera); the ſpider ophrys (O. aranifera); the yellow or muſk ophrys (O. monorchis); and the man ophrys (O. anthropophora).

The firſt ſort varies with three leaves.

And of the fourth ſort there are ſeveral varieties, as the fly-ſhaped; the great fly; the large green fly; the blue fly; and the yellow fly.

The ſixth ſpecies is fancied by ſome to reſemble a bee, by others a ſpider; from the breadth of the lip, and its being marked with different ſhades of brown, it derives its reſemblance to the latter. Others have diſcovered a likeneſs to a ſmall bird in the flower.

The eighth ſort varies in ſize, and in the colour of its flowers, from yellow green to bright ferruginous.

Method of Culture.—All theſe plants may be introduced into the different parts of pleaſure-grounds from the places where they grow naturally in this country, and be preſerved; but they do not admit of being propagated in them; the proper period for this purpoſe is juſt before the ſtalks decay, in the latter end of ſummer or beginning of autumn, as at that ſeaſon the bulbs will be in the beſt ſtate for growing ſtrong and flowering the following year. The roots ſhould be taken up with large balls of earth round them, and be planted again as ſoon as poſſible. They ſhould always be placed ſo as that the ſoils and ſituations may be as nearly as poſſible ſimilar to thoſe from which they were taken; thoſe taken from woods being planted out in ſhady ſituations; thoſe from boggy or marſhy places, in the more moiſt and boggy parts; and thoſe from dry elevated ſituations, in ſuch as have the greateſt degrees of dryneſs and are the moſt open. They ſhould afterwards be as little diſturbed as poſſible by any ſort of culture: with this ſort of management the roots will often continue for ſeveral years, flowering annually during the ſummer.

But in the culture of the ſixth ſort, Mr. Curtis ſucceeded by taking them up from their natural ſituations when in flower, and baring their roots no more than was neceſſary to remove the roots of other ſorts of plants; then filling large ſized garden-pots, with three parts good moderately ſtiff loam, and one part chalk mixed well together, paſſing them through a ſieve ſomewhat finer than a cinder-ſieve, afterwards planting the roots in them to the depth of two inches, and, where there is more than one, three inches apart, watering them occaſionally during the ſummer ſeaſon, in dry weather, and on the approach of winter placing the pots under the protection of a frame and glaſſes, in order to prevent their being injured by wet or froſts.

All the plants afford variety, and are highly ornamental in the clumps, borders, and other parts of ſhrubberies, &c.

OPHTHALMIC, in *Anatomy*, from οφθαλμος, *the eye*, a term applied to parts connected with the eye, as the artery, vein, nerve, ganglion, &c.

OPHTHALMICS, medicines proper for diſeaſes of the eyes.

Such are ophthalmic waters. (See Water.) Ophthalmic powders, ointments, &c. There is an excellent ophthalmic prepared of ſaccharum ſaturni.

OPHTHALMODYNIA, from οφθαλμος, and οδυνη, *pain*, an itching burning pain in the eye, without redneſs, and without any material increaſe of ſenſibility.

OPHTHALMOGRAPHIA, formed from οφθαλμος, *eye*, and γραφω, *I deſcribe*, that branch of anatomy which

conſiders

conſiders the ſtructure and compoſition of the eye, the uſe of its parts, and the principal effects of viſion.

Our countryman Dr. William Briggs has publiſhed an excellent ophthalmographia, and Piempius another.

OPHTHALMOPONIA, from ὀφθαλμος, and πονεω, *to labour*, an intenſe pain in the eye, rendering light intolerable.

OPHTHALMOPTOSIS, from ὀφθαλμος, and πτωσις, *a fall*, a protruſion or diſplacement of the eye. See EXOPHTHALMIA.

OPHTHALMORRHAGIA, from ὀφθαλμος, and ῥεω, *to flow*, bleeding from the eye or eye-lid.

OPHTHALMOSCOPIA, that branch of phyſiognomy which conſiders a perſon's eyes and looks; to deduce thence the knowledge of his temperament, humour, and manners.

OPHTHALMOXYSTRIS, from ὀφθαλμος, and ξυστρον, *a bruſh*, the operation of ſcarifying the eye with a bruſh, as anciently practiſed.

OPHTHALMOXYSTRUM, a bruſh for ſcarifying the eye.

OPHTHALMY, OPHTHALMIA, *Ophthalmitis*, derived from ὀφθαλμος, *the eye*, is the general name by which inflammation of this delicate and important organ is expreſſed.

Inflammation of the eye originates in the ſame manner, and demands the ſame kind of treatment, as inflammation in other parts of the body; the general obſervations, therefore, which have been delivered upon this ſubject in the article INFLAMMATION, are for the moſt part applicable to caſes of ophthalmy. In the preſent place it is our particular duty to conſider only the peculiarities of inflammation of the eye, and the circumſtances in which it differs from other ordinary inflammations.

Of all the diſeaſes of the eye, ſays the experienced Richter, ophthalmy is the moſt frequent. There are very few diſeaſes of the eye which do not ſometimes ariſe from it, and in many of them it is a neceſſary ſymptom or conſequence. The characteriſtic ſigns of the diſorder are pain and redneſs: the latter is particularly remarkable, as the healthy eye exhibits no red appearance whatſoever. It does not conſtantly happen, however, that redneſs is an obvious ſymptom of an inflamed eye; ſome violent ophthalmies are ſaid to be attended with little or no preternatural redneſs of the affected organ. Richter adduces, as inſtances, what he calls the *catarrhal*, or *rheumatic* ophthalmy, and the inflammation which chiefly affects the interior of the eye, a caſe that is termed *phlegmone oculi*. Beſides, even when the inflamed part is conſiderably reddened, it frequently occurs that the change is concealed, by reaſon of the impoſſibility of making the patient open his eye. The increaſed redneſs is always moſt conſpicuous in the white of the eye; but often in ſevere ophthalmies, the tranſparent cornea alſo becomes red, and bleeds, if punctured or cut. The aqueous humour has been obſerved to become of a red colour, an event which no doubt proceeded from extravaſated blood; and ſometimes ſmall veſicles, full of this fluid, have been formed upon the cornea. The dark red ſwelling of the conjunctiva, attendant on violent degrees of ophthalmy, and termed *chemoſis*, ariſes from an effuſion of blood underneath that membrane. The eye-lids, likewiſe, not unfrequently partake of the inflammatory redneſs. In caſes where the eye either cannot or muſt not be opened, it may always be inferred, that the eye-ball is inflamed, if the lower edge of the upper eye-lid, or the whole of this part, ſhould appear to be affected with ſwelling and redneſs.

The pain is the principal ſymptom of ophthalmy; and, indeed, when the eye cannot or muſt not be opened, it is the only one. It is of different kinds. In mild ophthalmies the patients experience a ſenſe of heat, or itching, or a ſort of preſſure, that ſeems as if it proceeded from the lodgment of a particle of ſand underneath the eye-lids; but, in ſevere caſes, the pain is of a burning, tenſe, ſhooting, throbbing deſcription. When the patient has a ſenſation as if the orbit were too ſmall, and as if the eye-ball protruded from not having ſufficient room; and when he ſuffers, particularly about the eye-brow, a violent, oppreſſive, tenſe pain, ſometimes extending from the affected ſide of the head to the occiput; it may be concluded, without riſk of miſtake, that the inflammation has attained the higheſt degree of violence, and that there is imminent danger of ſuppuration.

But even pain is not to be regarded as a conſtant and eſſential ſymptom of ophthalmy. There are, ſays Richter, ſome ſevere ophthalmies, which are accompanied with little or no pain; while certain milder caſes of inflammation of the eye ſometimes prove exceſſively painful. Examples of this kind are ſubject to variety. Hardy, unfeeling patients frequently make little complaint about pain, and the ſurgeon who truſts to their aſſurance, that the ſymptom is moderate or trifling, frequently finds, very unexpectedly, upon opening the eye-lids after a few days, the eye moſt vehemently inflamed, nay ſometimes actually in a ſtate of ſuppuration. Irritable ſubjects, on the contrary, often cannot bear a very ſlight degree of pain, and make the ſurgeon have recourſe to means, which are in reality unneceſſary. Experience proves alſo, that, in the majority of caſes, the pain is moſt violent at the commencement of the inflammation, at the very moment when the diſorder firſt originates, and that it afterwards diminiſhes, and even entirely ſubſides, notwithſtanding the inflammation continues in an unabated degree. It frequently happens, after an operation on the eye, that the patient only experiences pain for a few hours in the courſe of the firſt night, and afterwards remains completely eaſy. The ſurgeon ſhould never ſuffer himſelf to be deceived by this ſhort duration and quick ſubſidence of the pain; for, under theſe circumſtances, the eye is often found moſt ſeriouſly affected with inflammation. Old chronic ophthalmies are not uncommonly attended with conſiderable redneſs, and with little or no pain. Laſtly, it deſerves to be noticed, that the pain accompanying inflammation of the eyes is ſometimes periodical. In the generality of ſuch caſes, the patients only experience pain an hour or two in the night-time, and during the day are quite free from any degree of ſuffering. Theſe ſhort paroxyſms of pain, and long intervals of eaſe, muſt not be received as a criterion of the mildneſs of the inflammation; for the eye may yet be violently inflamed. That the eye is ſometimes exceedingly painful, without being affected with inflammation, will be hereafter explained. The ſurgeon muſt not truſt to any ſingle ſymptom; but form a judgment from the conſideration of all the circumſtances of the caſe together.

Beſides the ſymptoms already pointed out, there are ſeveral others, which, though they do not commonly accompany ophthalmy, ſometimes do ſo, and conſequently demand the attention of the ſurgeon. The inflamed eye occaſionally perceives and bears the light, juſt as if it were in a healthy ſtate: this is uſually the caſe in mild and favourable ophthalmies. Sometimes the eye is ſo irritable, that the entrance of a very ſmall quantity of light into it cauſes a profuſe diſcharge of tears, and intolerable pain. This ſtate of things manifeſts itſelf in ſevere ophthalmies, particularly in thoſe which have been termed *catarrhal*, *humid*, &c. and are attended with a copious ſecretion of irritating tears. Sometimes ophthalmy is accompanied with a diminution or total loſs of ſight. This event is of the worſt kind. The

blindneſs, which always indicates a violent and dangerous degree of inflammation, originates either from an opacity of the cornea, or a complete cloſure of the pupil, two not unfrequent conſequences of ſevere ophthalmy: or it may proceed from the effect of the inflammation upon the retina, and, in this caſe, the diſorder uſually leaves behind it the gutta ſerena. See GUTTA *Serena*.

Swelling, which is an ordinary ſymptom of inflammation of other parts, is alſo ſometimes obſerved in inflammation of the eyes, being particularly obvious in that portion of the conjunctiva which covers the white of the eye. In violent ophthalmies, this membrane ſwells in ſuch a degree, that it envelopes the cornea, and lies in a thick fold between the eye-lids, protruding betwixt theſe parts, and hindering them from being ſhut. In this ſort of caſe the whole eye-ball reſembles a piece of red fleſh. In ſevere ophthalmies, the tranſparent cornea likewiſe ſometimes ſwells very conſiderably, ſo as to become four and even eight times as thick as it is in the healthy ſtate. This tunic is generally rendered at the ſame time white and ſoft. When ſuch thickening extends inward, the anterior chamber of the aqueous humour is leſſened, and may be quite obliterated, the inner ſurface of the cornea being in cloſe contact with the iris. In this circumſtance the inflammation uſually occaſions a preternatural adheſion of the iris to the cornea; a diſorder that is technically named *ſynechia*. When the thickening of the cornea projects outwardly, the affection often ends in a *ſtaphyloma*; which ſee. Experience proves, however, that ſuch thickening and opacity of the cornea ſometimes entirely diſappear with the inflammation, this membrane re-aſſuming all its proper qualities. The eye-lids alſo frequently participate in the inflammation with the globe of the eye, and they ſwell in ſuch a degree, that it is altogether impoſſible to ſeparate them from each other. In ſevere ophthalmies, the whole eye-ball has been obſerved to be affected with preternatural ſwelling.

In caſes of ophthalmy, fever is alſo frequently an attendant. According to Richter, it is worthy of particular notice, that the fever is not always of one and the ſame kind; but preſents itſelf under three varieties. Sometimes it is the effect of the ſame cauſe which produces the inflammation, and, in this circumſtance, the ſame means of cure are indicated, both for the fever and the ophthalmy. The ophthalmy proceeding from diſorder of the gaſtric organ affords an illuſtration of the preceding obſervation, emetics and purgative medicines ſerving, in this inſtance, to cure both the fever and the inflammation of the eyes. The fever is ſometimes the conſequence of the inflammation: here the local affection precedes the conſtitutional one; the latter being always in proportion to the former, moderate when it is moderate, violent when it is violent. This kind of fever requires the employment of antiphlogiſtic means, whereby its cauſe, *viz.* the inflammation, is removed, and the name of inflammatory fever is particularly applicable to it. After ſurgical operations on the eye, and other injuries of this organ, a fever often ariſes even before the ſlighteſt inflammation is diſcernible. It appears to be owing to the patient's apprehenſion before the operation, and to the pain which he has ſuffered, and it demands the employment of ſoothing anodyne means, eſpecially opium combined with antimonials. Richter alſo enjoins us to be aware that the fever which attends inflammation does not always retain the type with which it firſt aroſe, but may in its courſe put on a complicated character, the cauſes of which may be in the nature of the patient's conſtitution, or be of an epidemic or endemial kind.

Ophthalmies, even thoſe which are not very ſevere, frequently produce incurable defects in the eyes; and, when we reflect upon the delicate ſtructure of theſe organs, we cannot be ſurpriſed at their being ſo ſuſceptible of injury. The moſt common conſequences of violent ophthalmies are; opacities of parts naturally tranſparent, eſpecially of the cornea and capſule of the cryſtalline lens; cloſure of the pupil; gutta ſerena; ſtaphyloma, &c. Sometimes the inflammation occaſions ſuppuration. It often gives riſe to ulcers upon the cornea, or margins of the eye-lids. When one eye is affected with inflammation, the other ſeldom continues free from this affection. Alſo, when the ophthalmy is owing to a local external cauſe, the other eye frequently participates in the inflammation. When once the eye has been violently inflamed from ſome cauſe or another, it continually retains, in many inſtances, a tendency to freſh inflammation, and ophthalmy is re-excited by the ſlighteſt cauſes. In ſevere ophthalmies, two different ſtages are often obſervable. The firſt is attended with heat, and conſiderable pain and fever; the ſecond is more chronic, being unaccompanied with pain or febrile ſymptoms. The eye is merely weakened, humid, and more or leſs red. This ſecond ſtage of ophthalmy is frequently very tedious, and much more difficult to cure, than the firſt.

Ophthalmies are divided into different kinds, according to the variety in the ſeat of the affection, in its degree of violence, in its duration, in its external ſymptoms, and, more eſpecially, in the cauſes of the complaint. With reſpect to the ſeat of the inflammation, it alſo deſerves notice, that there is no part of the eye which is exempt from the riſk of being inflamed, and that in ſevere ophthalmies, the inflammation extends over the whole eye-ball. In mild caſes, however, one part ſuffers a good deal more, and ſooner, than another. Sometimes it is the interior of the eye, which is alone, or principally affected, being the caſe that has been termed by writers *phlegmone oculi*. In this example the patient uſually experiences a ſhooting pain, extending through the whole globe of the eye to the vicinity of the eye-brows, and occaſioning a ſenſation as if the organ were ready to burſt. Indeed the whole eye-ball ſometimes does appear to be actually ſwelled and dilated. Frequently the pupil is cloſed; the aqueous humour bloody; and the cryſtalline lens rendered opaque. In ſtill more numerous examples, the patient is deprived of the power of viſion, notwithſtanding the pupil be clear and uncontracted. There is little external appearance of redneſs about the eye. But the diſorder rarely continues long in this ſtate, a violent degree of external inflammation moſtly enſuing. The preceding caſe of internal ophthalmy is always attended with great danger of incurable blindneſs.

The effects of ſevere ophthalmy ſometimes extend to the tranſparent cornea, which membrane ſwells, and is rendered ſoft and white; or elſe blood-veſſels are diſtinctly ſeen ramifying upon it; or little bloody effuſions are formed over it. The eye-lids are alſo often affected in ophthalmy. Sometimes it is merely their inner ſurface which is inflamed, in which circumſtance the inflammation is ordinarily very painful. In other inſtances, it is their margins which are chiefly affected, and then ulcerations of the tarſi, and detachment of the ciliæ, not unfrequently enſue. Sometimes the whole eye-lid is inflamed; and in this caſe, it uſually happens that the eye cannot be opened at all, or not without conſiderable difficulty.

The portion of the conjunctiva covering the white of the eye is generally the principal ſeat of ophthalmy, and it may be affected in various ways. Sometimes merely a circumſcribed red ſpot, of different ſizes and ſhapes, is obſervable in one of the corners of the eye, appearing to ariſe from

a ſlight

a ſlight effuſion of blood in the cellular ſubſtance underneath the conjunctiva, and in general it changes its ſituation. For inſtance, if it be to day at one of the angles of the eye, to-morrow it will be found at the lower margin of the cornea. Such mild inflammation is often entirely unattended with pain, and in the majority of caſes the uneaſineſs which the patient ſuffers is inſignificant, and in the courſe of a few days ſpontaneouſly diſappears. The uſual exciting cauſes of the complaint are, violent ſtraining in vomiting or coughing, fright, a pointed extraneous body that has fallen into the eye, &c. Sometimes only a plexus of varicoſe veſſels can be ſeen near the external or internal commiſſure, running horizontally towards the cornea. When theſe veſſels do not reach this laſt membrane, the patient has no complaints, excepting a weeping of the eye, and a ſenſation of preſſure, ſeeming as if it proceeded from the lodgment of ſome foreign body under the eye-lids. But, in certain examples, ſome of the veſſels extend over the tranſparent cornea, and then it commonly happens that a cloudineſs accompanies the varicoſe affection of the veſſels, and proves a conſiderable impediment to viſion. This caſe, the *ophthalmia varicoſa* of ſurgical writers, is very obſtinate, and can ſeldom be relieved without an operation: it is for the moſt part a conſequence of violent acute ophthalmy.

Sometimes the white of the eye is interwoven with numerous ſmaller or larger blood-veſſels, either at its whole circumference, or elſe merely in the vicinity of either angle, the veſſels being plainly more or leſs diſtinguiſhable from one another. At the ſame time the patient has a burning ſenſation in his eye, and in general there is a copious effuſion of tears. Though this kind of inflammation is not violent, it is far from being unimportant. The more numerous the red veſſels are, the leſs diſtinct they are from one another; and the more uniformly red the eye appears, the more ſevere is the diſorder. The whole of the white of the eye is ſometimes not only affected with general redneſs, but the conjunctiva is ſwelled in ſuch a degree, that it projects between the eye-lids, and even forms a protruſion beyond them; leaving in the middle of the eye-ball a deep depreſſion, in which the cornea is ſituated; or elſe enlarged in ſuch a manner, that this laſt membrane is totally covered with it. In the latter caſe, the whole eye-ball reſembles a maſs of red fleſh. This ſpecies of ophthalmy, which is termed *chemoſis*, is generally attended with inflammation of all the internal and external parts of the eye, vehement pain, much fever, and imminent danger of ſuppuration. The ſwelling of the conjunctiva ariſes from an actual extravaſation of blood in the cellular membrane underneath it.

With reſpect to the duration of ophthalmies, they are divided into the *acute* and *chronic*. The generality of acute inflammations of the eyes at laſt terminate in the chronic form of the complaint. The attacks both of acute and chronic ophthalmies alternately come on and diſappear at certain times, and the diſorder is then termed *periodical*. All theſe varieties in the courſe of the diſeaſe permit us to draw no inferences which can be depended upon with regard to the proper mode of treatment. The ſame cauſe ſometimes produces an acute, ſometimes a chronic, ſometimes a periodical ophthalmy. Nay, the ſame inflammation of the eyes frequently changes its character, becoming, in turns, acute, chronic, and periodical. From ſuch variations alſo no certain information can be derived with reſpect to the prognoſis. It is occaſionally an unfavourable event, when an acute ophthalmy becomes chronic, while in other inſtances the change from the chronic to the acute form of the complaint is equally bad. Although chronic ophthalmies are generally not attended with much danger of the ſight being deſtroyed, yet they are ordinarily more difficult of cure than acute caſes, becauſe their cauſes are for the moſt part exceedingly complicated, inveterate, and not eaſily detected.

Ophthalmies are likewiſe diſtinguiſhed into ſeveral kinds, by a variety of external appearances. The inflamed eye is ſometimes ſo dry that the cornea is quite hard and ſcaly, and the eye and eye-lids cannot be moved without pain. It is to this caſe that the technical appellation of *xerophthalmia* is applied. Sometimes an extraordinary quantity of tears is diſcharged from the inflamed eye, the diſorder being then named *ophthalmia humida*. The tears may be very acrid and irritating, or entirely free from all hurtful qualities. In particular inſtances the inflamed eye is neither immoderately dry nor moiſt. The ſtimulus of gentle inflammation, operating upon ſecreting organs, increaſes the ſecretion, by increaſing the action of the veſſels; but the ſtimulus of violent inflammation puts a ſtop to ſecretion, probably by producing a ſpaſmodic conſtriction of the ſecerning arteries. Hence dry ophthalmies are always more ſevere than ſuch as are termed humid. It is conſtantly a ſign of mildneſs when the ſecretion of the tears is neither increaſed nor leſſened. Ophthalmies of the dry kind are moſt apt to bring on ſuppuration of the eye; while ſuch caſes as are accompanied with an effuſion of acrid irritating tears are moſt liable to occaſion ulceration of the tranſparent cornea, or of the margins of the eye-lids. Sometimes the inflamed eye is covered with thick purulent matter, which, in the night-time, glues the eye-lids together, a part of it becoming hard, and adhering to the eye-laſhes. This caſe is termed the *ophthalmia purulenta*. In this example, the Meibomian glands at the edges of the eye-lids are particularly affected, and ſecrete the purulent matter. The moſt intereſting diſtinctions of ophthalmy are founded upon the cauſes of the diſeaſe, and of theſe notice will be taken in ſpeaking of the mode of treating particular caſes.

In the treatment of ophthalmy, there are ſeveral indications to be fulfilled. The moſt important one is founded upon the cauſe of the complaint; all the others are of inferior conſequence. When the cauſes are numerous, the curative indications may alſo be ſo. The ſecond moſt material indication is that ariſing from the character of the diſorder, which being inflammatory, of courſe demands antiphlogiſtic treatment. Beſides theſe two principal indications, which the ſurgeon muſt carefully and conſtantly attend to in the cure of ophthalmy, there are others of a collateral nature, depending upon the different appearances of the complaint, the various degrees of violence, the differences in the ſituation of the inflammation, the patient's conſtitution, &c. Although theſe laſt ſhould not interfere with the chief means of cure, they often point out uſeful auxiliary meaſures.

We ſhall follow Richter, and firſt offer ſome general obſervations on the treatment of ophthalmy, and afterwards ſpeak of the mode of curing each particular ſpecies of the diſorder. With the exception of the humid ophthalmy, attended with an effuſion of acrid tears, and chronic caſes unaccompanied with pain, every inflamed eye ſhould be kept from the light and air, which act as ſtimuli, ſo as to increaſe the inflammation, and prove particularly detrimental, the light producing alſo a great deal of pain. The uſual bandage, conſiſting of a compreſs laid over the eye, and faſtened with a fillet, fulfils the intention, but yet it is apt to compreſs and irritate the eye. The compreſs ſoon becomes wet with the tears which are diſcharged, and the eye and adjacent parts are kept continually in a moiſt ſtate, which, in certain ophthalmies, eſpecially the acrid humid caſe, is very hurtful. Richter thinks the propoſal of putting over the

the eye a ſoft bit of ſponge, inſtead of a compreſs, altogether uſeleſs; it is true that the ſponge will not make inconvenient preſſure on the eye, but the organ will be, as it were, in a kind of warm bath. In the majority of inſtances, it is unneceſſary to lay a compreſs upon the eye itſelf; for when the inflammation is of any importance, the edges of the eye-lids very quickly become adherent together. In this circumſtance, it is always preferable to put the compreſs on the forehead, and let it hang down over the eye, care being taken to faſten it with a band, or elſe to pin it to the patient's cap. When the eye-lids are not cloſed, a compreſs muſt be carefully kept on the eye. To this practice, however, there are a few caſes forming exceptions. Beſides guarding the eye from the light and air, it is alſo proper to prevent all motion of the eye and eye-lids, as ſuch motion would evidently irritate the inflamed part. On this account, Richter conceives, that a compreſs, which is merely allowed to hang down over the eye, does not do in every caſe what ought to be done.

Both eyes, even though one only may be inflamed, ought always to be covered in one of the foregoing manners. The ſtimulus of the light upon the ſound eye alſo affects the diſeaſed one, and the latter generally moves together with the former. The compreſs ſhould be frequently changed, becauſe the diſcharge would ſoon render it hard and ſtiff, in which ſtate it would prove offenſive to the eye. Sometimes the eye-lids adhere ſo cloſely together, that the tears cannot eſcape, ſo that they accumulate under theſe parts, which become prodigiouſly diſtended, and hang down in the form of a pouch. This caſe is not of frequent occurrence; but it does occaſionally happen, and may be miſtaken by an incautious ſurgeon for an œdematous ſwelling of the eye-lids. If the eye-lids be ſeparated a little from each other at the internal angle, the confined tears will flow out in a ſmall ſtream, and the ſwelling of the eye-lids immediately ſubſide. This expedient muſt be adopted every day, and even repeatedly, eſpecially when the tears are ſharp and irritating.

Sometimes in ophthalmies the upper eye-lid ſwells in ſuch a degree, that it hangs down and covers the whole, or the greater part of the lower one. In theſe caſes, eſpecially when the inflammation is of a certain kind, a quantity of viſcid, tough, thick matter accumulates underneath the upper eye-lid upon the external ſurface of the lower one, and very ſoon becomes ſo acrid and irritating, that it materially tends to keep up the effuſion of tears, burning and ſhooting pains, and even the inflammation and ſwelling of the eye-lid itſelf. The globe of the eye is likewiſe liable to be injured by ſuch a collection of diſcharge. In caſes of this ſort, it is not an unimportant rule to raiſe the upper eye-lid occaſionally, and waſh away the diſcharge accumulated under it. By this means, the patient uſually experiences conſiderable relief of all his unpleaſant ſenſations. Opening the adherent eye-lids, in caſes of ophthalmy, requires ſome care, in order that the eye may not be irritated or otherwiſe hurt, particularly when the inflammation is the conſequence of a ſurgical operation. In general, it will be found that merely the eye-laſhes ſtick to the ſkin of the lower eye-lid, and conſequently that, for the purpoſe of opening the eye, nothing more is neceſſary than to looſen the above hairs. The object can be beſt fulfilled by ſoftening the diſcharge, which makes the eye-laſhes adhere, with a little warm milk, or milk and butter, and then lifting them up with the end of a probe. When this is done, the eye may uſually be opened with the utmoſt facility.

Beſides the means of cure required by the foregoing indications, in caſes of ophthalmy, external topical applications may be employed with advantage. Theſe are beſt in the form of an eye-water, or collyrium. Powders, blown or ſprinkled into the eye, always produce irritation. Salves will not readily remain in contact with the eye, which is moſtly ſurrounded with aqueous ſecretions: they only remain applied to the eye-laſhes and ſkin of the eye-lids; and they are attended with the inconvenience of being liable, unleſs quite recently prepared, to produce redneſs, pain, and heat. Earthy indiſſoluble ingredients, alſo, ſhould never be put into collyria; for they remain in the eye after the employment of theſe applications, and always occaſion a degree of irritation. It appears to Richter, that the ordinary mode of uſing lotions for the eye by wetting compreſſes, and laying theſe over the ſhut eye-lids, is ineffectual and hurtful. Ineffectual, becauſe, ſays this writer, how can the operation of a collyrium extend to the globe of the eye through the eye-lids, which are frequently very much thickened and ſwelled? Hurtful, becauſe the wet compreſs ſoon becomes warm, and warm moiſt applications do harm to ſeveral kinds of ophthalmy. Whenever the compreſs becomes dry, it is rendered hard and ſtiff, and in this ſtates it irritates and diſturbs the eye. The beſt plan is to inſinuate a few drops of the collyrium into the inner angle of the eye, while the patient lies upon his back. Thus, the application not only comes into contact with the parts on which it is to act, for it ſpreads over the whole eye-ball towards the external angle, eſpecially when the patient moves the eye-lids, and turns his head ſideways, but it alſo continues a certain time upon the affected parts, if the patient be kept upon his back, and a few freſh drops be every now and then introduced.

Particular caſes occur, in which the inflamed eyes are benefited by no wet topical applications. Such deviations from what is common cannot always be diſcovered *à priori*. A ſhort trial ſoon evinces the powerful effect of this deſcription of local remedies, and the neceſſity of abſtaining from them. All external applications muſt now be left off, or only ſuch as are dry employed. Richter mentions a mixture of camphor, elder flowers, and chamomile, in little bags, as being an uſeful remedy in theſe peculiar examples.

Moſt of the external applications employed in caſes of ophthalmy, admit of being divided into two kinds, diſcutients, aſtringents, and ſoothing emollients. Acute ophthalmies in the incipient ſtage, while bleeding has not been ſufficiently practiſed, and the eyes are yet very painful, will not bear the firſt claſs of remedies, which, acting as ſtimulants, would increaſe the pain and inflammation. But, in proportion as the pain ſubſides, and the neceſſity for bleeding diminiſhes, and as the inflammation aſſumes a chronic nature, ſuch applications become more uſeful. The more painful and acute the ophthalmy is, the more proper are the topical remedies of the ſecond claſs. Certain ophthalmies, alſo, which are not very violent and acute, but which are attended with conſiderable ſenſibility in the eyes, require the uſe of ſoothing applications. On the other hand, the greater the degree of redneſs and ſwelling in the inflamed eye, provided the pain be moderate, the more ſtrongly are tonics and aſtringents indicated. Ophthalmies, accompanied with a copious diſcharge of acrid tears, are moſt benefited by emollient allaying remedies. Sometimes inflamed eyes appear to derive no good from any kind of external applications whatſoever.

As Richter obſerves, there are caſes in which the ſurgeon foreſees the diſorder, and by timely prophylactic meaſures has it in his power to prevent, or, at all events, leſſen it. Such inſtances particularly occur in ſurgical operations upon the eyes. Here inflammation is always to be expected, and

it

it not unfrequently proves a cauſe of the ill ſucceſs of the operation. The ſole deſign of all preparatory treatment adopted before the latter proceeding, is to leſſen and prevent the apprehended inflammation. With this view, it was once the cuſtom to keep the patient a certain time on a low debilitating diet, to hinder him from taking the air, to exhibit weakening aperient neutral ſalts, and even to have recourſe to veneſection. By ſuch means, the irritability of the patient was increaſed, and, of courſe, the enſuing inflammation, and all its bad effects, were aggravated. Beſides, the long formal preparation tended to increaſe the alarm which the patient generally felt before the operation was undertaken; while perſiſting in the exhibition of aperient ſalts checked the ſecretion from the ſkin, weakened the ſtomach and bowels, and diſpoſed the patient to gaſtric complaints, which were ſure to have an unfavourable effect upon the conſequences of the operation. Repeated experience proves, ſays Richter, that operations on the eyes are performed with moſt ſucceſs upon patients who are ſtrong, hardy, healthy, and little irritable, and who have not ſubmitted to any of the above preparatory treatment. The only things which can be of uſe before the operation conſiſt in endeavouring to quiet the patient's apprehenſions, by repreſenting what is about to be done as ſafe, and by no means very painful; in not keeping the patient a long while in fearful expectation of the operation; in letting the patient take exerciſe in the open air; in giving him antimonials in order to promote perſpiration, by which means the riſk of inflammation will be materially leſſened; and laſtly, in adminiſtering an opiate, half an hour before the operation, when the patient ſeems reſtleſs. Theſe directions, however, are only applicable to caſes in which the patient is, in other reſpects, quite healthy; for it is eſſentially neceſſary to obviate any other diſeaſes, or defects, which may prevent the ſucceſs of the operation. (See Richter's Anfangſgr. band iii. kap. 1.) From theſe general obſervations we ſhall next proceed to the conſideration of each particular ſpecies of ophthalmy.

Of the mild acute Ophthalmy.—This form of the complaint is characteriſed by redneſs of the conjunctiva and lining of the eye-lids, an unnatural ſenſation of heat in the eyes, uneaſineſs, itching and ſhooting pains, as if particles of ſand had got between the palpebræ and the eye-ball. At the place where the pain ſeems to be moſt ſevere, there are ſome blood-veſſels which appear more turgid and prominent than other veſſels of the ſame claſs. The patient of his own accord keeps his eye-lids cloſed; for he feels a wearineſs and reſtraint in opening them, and, by ſhutting them, he alſo moderates the action of the light, to which he cannot expoſe himſelf, without increaſing the burning ſenſation, lancinating pain, and effuſion of tears from the eye. If the conſtitution is irritable, the pulſe will be a little accelerated, particularly towards the evening; the ſkin will be dry, ſlight ſhiverings will occur, and, in ſome inſtances, nauſea and inclination to vomit. See Scarpa's Oſſervazioni ſulle Principali Malattie degli Occhi. cap. 7.

This complaint is often the conſequence of a cold, in which the eyes, as well as the pituitary cavities, fauces, and trachea, are affected. It is not unfrequently occaſioned by change of weather, ſudden tranſitions from heat to cold, the prevalence of eaſterly winds, journies through damp unhealthy ſandy countries in the hot ſeaſon of the year, expoſure of the eyes to the vivid rays of the ſun, &c. Hence, as Scarpa has judiciouſly remarked, it does not ſeem extraordinary that it ſhould often make its appearance as an epidemic, and afflict perſons of every age and ſex. Beſides the preceding remote cauſes of ophthalmy, authors have enumerated, as others, the ſuppreſſion of ſome habitual evacuation, ſuch as bleedings from the noſe, or piles, ſtoppage of the menſes, &c. Alſo affections of the primæ vitæ, worms, dentition, &c.

The mild acute ophthalmy may, in general, be eaſily cured by means of low diet, gentle purging with ſmall repeated doſes of the antimonium tartarizatum, and after making ſearch for any extraneous body that may have inſinuated itſelf beneath the eye-lids, repeatedly waſhing the eye with a warm decoction of mallow leaves, and covering it with any very ſoft emollient poultice, which ſhould be included in ſmall bags of fine muſlin. Scarpa thinks the fluid remedy may be moſt conveniently applied by means of an eye-glaſs. He orders the antimonium tartarizatum to be taken as follows: ℞ Antim. tart. gr. j. Decocti hordei lbiſs cryſtal. Tart. ʒi. Sacchari purif. ʒvj. Miſce. This quantity is to be taken in divided doſes every day. Scarpa, inſtead of the barley water, preſcribes the decoction of dog-graſs, which does not appear to us to be eſſential.

Under this treatment, the inflammatory ſtage of the mild acute ophthalmy commonly ceaſes in the courſe of four or five days. The patient no longer complains of that oppreſſive ſenſe of heat, tenſion, throbbing, &c. previouſly experienced, and he can now bear a moderate light, without ſo profuſe a diſcharge of tears, as uſed previouſly to be the conſequence. In this ſtate, how red ſoever the tunica conjunctiva may appear, it is no longer affected with acute inflammation, and the ophthalmy has relapſed from its acute ſtage into that attended with relaxation and weakneſs of the veſſels of the conjunctiva and membranous lining of the eye-lids. Emollients are now improper; in lieu of them, aſtringent corroborant collyria ſhould be uſed, by means of which the relaxed veſſels of the conjunctiva and eye-lids will recover their original tone, and the ophthalmy be totally removed. One of the following eye-waters, which are ſimilar in quality to thoſe directed by profeſſor Scarpa, may be employed. ℞ Zinci ſulphatis gr. v. Aquæ roſæ ʒiv miſce. Vel plumbi ſuperacetatis gr. viij. Aquæ fœniculi ʒvj. Spir. camphorati ♏ x miſce. The mild ophthalmy, originating from cauſes which render it an epidemic, ſo quickly paſſes through the firſt inflammatory ſtage, that this ſtage is ſcarcely obſervable, and, according to Scarpa, it is the only caſe in which cold aſtringent applications are immediately neceſſary.

Of the ſevere acute Ophthalmy.—The ſevere acute ophthalmy is attended with the ſame deſcription of ſymptoms as the mild, but in a more aggravated form. The ſenſation of heat in the eyes is burning; the conſtriction of the whole eye-ball and eye-lids ſpaſmodic; the preſence of even a faint light intolerable. Sometimes the effuſion of tears is continual, very copious, and blended with mucus, which is apt to make the eye-lids adhere together. Sometimes this ſecretion is almoſt ſuppreſſed, and the eyes become preternaturally dry. The ſympathetic fever is conſiderable, with reſtleſſneſs and intolerable pain about the back part of the head. The pupil is contracted; the conjunctiva of an uniformly deep red colour. On the anterior hemiſphere of the eye, amongſt the moſt prominent faſciculi of veſſels, may be diſtinguiſhed a delicate vaſcular network, continued from one faſciculus to another; but all being equally turgid with blood, and coiled as it were together, ſeem to form a kind of excreſcence, which riſes above the ſurface of the eye, and has a tendency to project forwards beyond the eye-lids.

From the immoderate action of the inflamed veſſels, blood is occaſionally extravaſated into the cellular ſubſtance, connecting the tunica conjunctiva with the ſclerotica. Hence the firſt of theſe membranes, which is naturally looſe, becomes enormouſly extended, and elevated in front of the eye,

eye, ſo as to make the tranſparent cornea ſeem quite ſunk, and prevent the eye from being completely ſhut. *Chemoſis* is the term uſually applied to this ſort of caſe.

The ſevere acute ophthalmy generally affects only the outer part of the eye-ball; but ſometimes the interior of the eye is alone affected, or, at all events, more ſo than the exterior. There is little change in the external parts, the patient ſuffers extreme pain on expoſing his eye to the fainteſt light; the iris has a red appearance; the pupil is exceedingly contracted; and the aqueous humour is occaſionally red and turbid. From theſe circumſtances, Scarpa thinks it not irrational to ſuſpect, that in the higheſt degree of internal ophthalmy, there may be an extravaſation of blood in the chambers of the eye, eſpecially betwixt the choroid and ſclerotic coats. Hence may ariſe the termination of the internal ophthalmy in amauroſis, ſo common when the caſe does not end in ſuppuration.

The ſevere acute ophthalmy demands the moſt rigorous adoption of the antiphlogiſtic treatment. Tardineſs in procuring evacuations, eſpecially of blood, too often gives the diſeaſe time to advance to the ſtate of chemoſis; or elſe to a condition in which ſuppuration, or an extravaſation of lymph within the eye, is threatened; while, in other inſtances, the inflammation degenerates into an obſtinate chronic ophthalmy, ariſing from the exceſſive weakneſs produced in the veſſels of the conjunctiva. Both general and topical blood-letting ſhould therefore be ſpeedily practiſed. Leeches ſhould be applied to the vicinity of the eye-lids, eſpecially, ſays Scarpa, about the inner canthus, on the vena angularis, where it joins the frontal, deep orbitar, and tranſverſe vein of the face. See Saggio di Oſſervaz. &c. cap. 7.

Mr. Ware objects to leeches being put on, or very near the eye-lids, as they have ſometimes cauſed a conſiderable ſwelling of thoſe parts, and increaſed inſtead of leſſening the irritation. In ordinary caſes, this gentleman recommends applying three in the hollow of the temple, about an inch and a half from the outer part of the orbit. There is one mode of bleeding, in caſes of ophthalmy, perhaps productive of more benefit than any other, and this probably on account of its acting at once both as a general and topical application; the plan alluded to is that of opening the temporal artery.

There is another method of bleeding, which deſerves to be particularly noticed, as having frequently proved ſuperiorly efficacious. The viſible blood-veſſels on that part of the conjunctiva, which covers the inſide of the eye-lids, are much more numerous than thoſe which are obſervable on the white of the eye. Hence, in ophthalmy, the inflammation ſeems greateſt on the inſide of the eye-lids, where the blood-veſſels are often not only much increaſed in number, but are alſo extremely full and turgid. Sometimes alſo the whole inſide of the eye-lids, particularly of the lower one, is ſo much enlarged as to be conſtantly turned outward. In both theſe caſes great benefit has been derived from ſcarifying the inner ſurface of theſe parts with a lancet, by which means a conſiderable quantity of blood has been removed. When the upper eye-lid is very œdematous in ophthalmy, and its thickneſs prevents the application of remedies to the eye, a few punctures made in the outſide of the ſwelled part, near its edge, will let out a quantity of bloody water, and materially leſſen the ſwelling. When the tumefaction of the everted eye-lids is very conſiderable, great and ſpeedy relief has often been given, by cutting off a piece of the inſide of thoſe parts with a pair of curved ſciſſars. Ware on Ophthalmy, p. 39, 40.

General bleeding, though copious, and aſſiſted by the topical application of leeches, does not always prove adequate to the removal of the high degree of inflammation attendant on chemoſis. It is expedient to employ additional means, in order to give exit to the blood effuſed in the cellular ſubſtance, between the conjunctiva and ſclerotica, and raiſing the firſt of theſe membranes ſo much above the level of the cornea. With this view Scarpa recommends making a circular inciſion in the conjunctiva near the margin of the cornea, with a pair of curved ſciſſars. As a lancet, however, makes a cleaner cut, it is perhaps preferable for the operation, and ſcarifications might ſuffice both for the diſcharge of the extravaſated blood, and of that diſtending the veſſels of the conjunctiva itſelf. But, according to Mr. Ware, there cannot be an eaſier, nor a more effectual remedy in chemoſis, than æther. A few drops are to be poured into the palm of the hand, and diffuſed over it, which may be immediately done by preſſing the other hand againſt it. The hand is then to be applied to the eye, and kept ſo cloſe to it that the ſpirit, as it evaporates, may inſinuate itſelf into the part affected, and bring about the abſorption of the extravaſated blood. In a few inſtances of chemoſis, in which the ſwelling and inflammation have been conſiderable, Mr. Ware has found the following application of ſingular ſervice: ℞ Interiorum foliorum recentium lactucæ ſiſſilis ℥iij. Coque cum aquæ puræ ℥ſs in balneo mariæ pro ſemihorâ; tunc exprimatur ſuccus, et applicetur paululum ad oculos et ad palpebras ſæpe in die.

After general and topical bleeding, aperient medicines of the moſt gentle kind ſhould be adminiſtered; ſoda phoſphorata, pulp of tamarinds, potaſſæ ſupertartras, and magneſiæ ſulphas, are the moſt proper. When the ſtomach is affected, Scarpa alſo recommends an emetic, as being of ſingular ſervice in caſes of ophthalmy.

When bleeding and other evacuations have been practiſed, the next moſt uſeful meaſure is the application of a bliſter to the nape of the neck. Scarpa obſerves that the integuments in this ſituation, and behind the ears, ſympathize more cloſely with the eyes than any other part of the ſkin does. Many practitioners, however, and among them Mr. Ware, prefer bliſtering the temples. The latter ſays, "when the leeches have fallen off, and the conſequent hemorrhage has ceaſed, I would adviſe a bliſter, of the ſize of half-a-crown, to be applied to the temples, directly over the orifices made by the leeches; and I have found that the ſooner the bliſter has followed the bleeding, the more efficacious both have proved." When the ophthalmy has been very violent, and reſiſted the common method, Mr. Ware adds, that the moſt beneficial effects have alſo been ſometimes produced by the application of a bliſter large enough to cover the whole head. P. 43, 44.

At firſt, topical emollient applications to the eye are moſt beneficial; ſuch as mallows boiled in new milk, bread and milk poultices, or the ſoft pulp of a baked apple; all included in fine little muſlin bags. Remedies of this deſcription ſhould be renewed at leaſt every two hours. The patient ſhould be directed to obſerve perfect quietude, and to lie with his head in an elevated poſition. To keep the eye-lids from adhering together in the night time, the ſpermaceti cerate is proper. When the ophthalmy is accompanied with a violent pain in the head, Mr. Ware recommends a ſtrong decoction of poppy heads to be applied as a fomentation. P. 51.

Under the preceding plan of treatment, the acute ſtage of ſevere ophthalmy uſually abates in the courſe of a week. The burning heat, and darting pains in the eyes, and the febrile diſturbance of the conſtitution, all ſubſide. The patient is comparatively eaſy, and regains his appetite. The eye-lids loſe their tenſion and wrinkle. A diſcharge of thick

matter

matter takes the place of a ſecretion of thin ſerum, or of a preternatural dry ſtate of the eyes. Theſe organs can now be opened, without experiencing vaſt irritation from a moderate light. In this ſtate, notwithſtanding the eyes may continue red, and the conjunctiva ſwollen, all evacuations are to be left off, as well as the uſe of topical emollients. For theſe latter, aſtringent corroborant collyria are to be ſubſtituted. Scarpa recommends the following application: ℞ Zinci ſulphatis gr. vj. Aq. diſtillatæ ℥vj. Mucil. ſem. cydon. mali ℥j. Spirit. camphor. guttas paucas. Miſce et cola. This collyrium may be injected with a ſyringe, between the eye and eye-lids, once every two hours; or, if the practitioner prefer the method, the eye may be bathed in the lotion by means of an eye-cup. Such perſons as cannot bear cold applications to the eye, muſt have the ſame kind of collyrium a little warmed; but it may be uſed cold, as ſoon as the irritability begins to decreaſe.

The tinctura thebaica of the old London Diſpenſatory proves a moſt efficacious remedy for the ſecond ſtage of acute ophthalmy, or that connected with weak vaſcular action in the part affected. Two or three drops may be introduced, between the eye-lids and globe of the eye, twice a day in common caſes; but in others, attended with more ſenſibility, once will at firſt be ſufficient. Mr. Ware, who brought this application into repute, has found, that introducing two or three drops of this medicine at the inner canthus, and making them glide gradually over the eye, by gently drawing down the lower eye-lid, proves equally beneficial, and leſs painful, than dropping them at once on the eye-ball. Immediately the application is made, it generally creates a copious flow of tears, a ſmarting pain, and a ſenſe of heat in the eyes, which inconveniences, however, ſoon ceaſe, and the eyes become clearer, and feel evidently improved. It ſhould be well underſtood, that the tinctura thebaica may be uſed too extenſively; and that it is only proper for caſes, in which the acute ſtage of the diſorder has been previouſly leſſened by blood-letting, aperient medicines, and bliſters. Scarpa has expreſsly pointed out, that it is a remedy, which is uſeful only when the violence of the pain and the inability to bear the light are abated.

Whenever the patient can eaſily bear a moderate degree of light, all coverings ſhould be removed from the eyes, except a ſhade of green or black ſilk. A brighter light ſhould be gradually admitted every day into his chamber; ſo that he may become habituated as ſoon as poſſible to the open day-light. Nothing, ſays the judicious Scarpa, has a greater tendency to keep up and increaſe the morbid irritability of the eyes, than keeping them unneceſſarily long in a dark ſituation, or covered with compreſſes and bandages.

Purulent Ophthalmy of Children.—This ſpecies of ophthalmy produces ſuch a ſwelling of the eye-lids, as almoſt entirely prevents their ſeparation from each other. Should the ſurgeon obtain a view of the membrane lining them, it will be found to be wrinkled, and converted into a red villous ſurface, ſomewhat like the inner coat of the rectum, when protruded in young children. (Warner on the Human Eye, p. 42.) Sometimes in the child's fits of crying the eye-lids become everted, and continue ſo, until rectified by an attendant. No ſooner is the firſt ſhort attack of inflammation paſt, than a diſcharge of thick yellow matter enſues, truly ſurpriſing in quantity, partly ſecreted by the Meibomian glands, but chiefly by that villous, fungus-like ſurface, into which the lining of the palpebræ ſeems converted. If the eye-lids admit of being opened, the matter may be ſeen diffuſed over the whole ſurface of the eye; and its confinement between the ſwelled eye-lids and the eye-ball contributes ſtill more to aggravate the pain, increaſe the inflammation, and often induce ulcers, or ſpecks, either over a part or the whole of the cornea. If a ſpeedy check be not ſoon put to this diſtreſſing malady, it frequently renders the cornea ſo opaque and thickened, as to form what is termed *ſtaphyloma*. (See this word.) The cornea has even been known to burſt, the humours to be diſcharged, and the eye to ſink in the orbit. The febrile ſymptoms are at firſt ſevere; the infant is continually fretful and reſtleſs, and a diarrhœa is not unfrequently concomitant. The affection of the eyes is occaſionally accompained with eruptions on the head, and with marks of a ſcrofulous conſtitution. Ware, p. 138. &c.

The antiphlogiſtic treatment ſhould be quickly oppoſed to the progreſs of the diſeaſe. The temporal arteries ſhould be opened, or leeches applied to the temples, or neighbourhood of the eye-lids, and a bliſter put on the nape of the neck or temples. The child ſhould be kept in a cool room, and not covered with much clothes. If no diarrhœa ſhould prevail, it is proper to purge with a little rhubarb, or magneſia, in ſyrup of violets.

A ſurgeon is ſeldom called in before the firſt ſhort inflammatory ſtage has ceaſed, and an immenſe diſcharge of matter from the eyes has commenced. Of courſe, emollient applications are generally improper. Aſtringents and corroborants are immediately indicated, in order to reſtore to the veſſels of the conjunctiva and eye-lids their original tone, to rectify the villous and fungous appearance of the lining of the palpebræ, and thus finally to check the morbid ſecretion of matter. For this purpoſe, Mr. Ware ſtrongly recommends the aqua camphorata of Bates's Diſpenſatory: ℞ Cupri vitriolati. Bol. Armen. ā ā ℥iv. Camphoræ ℥j. M. & f. pulvis, de quo projice ℥j. in aquæ bullientis Ibiv. amove ab igne, et ſubſidant fæces. Mr. Ware, in his late Remarks on Purulent Ophthalmy, 1808, obſerves, that he uſually directs the aqua camphorata, as follows: ℞ Cupri vitriolati. Bol. Armen. ā ā gr. viij. Camphoræ gr. ij. Miſce, et affunde aquæ bullientis ℥viij. Cùm lotio ſit frigida, effundatur limpidus liquor, et ſæpiſſimè injiciatur paululum inter oculum et palpebras. This remedy poſſeſſes a very ſtyptic quality; but it is much too ſtrong for uſe, before it is diluted; and the degree of its dilution muſt always be determined by the peculiar circumſtance of each caſe. Mr. Ware ventures to recommend about one dram of it to be mixed with an ounce of cold clear water, as a medium or ſtandard, to be ſtrengthened or weakened as occaſion may require. (P. 143.) The remedy muſt be applied by means of a ſmall ivory or pewter ſyringe, the end of which is a blunt-pointed cone. The extremity of this inſtrument is to be placed between the edges of the eye-lids, in ſuch a manner, that the medicated liquor may be carried over the whole ſurface of the eye. Thus the matter will be entirely waſhed away, and enough of the ſtyptic medicine left behind to interrupt and diminiſh the exceſſive diſcharge. According to the quantity of matter, and the rapidity with which it is ſecreted, the ſtrength of the application, and the frequency of repeating it, muſt be regulated. In mild recent caſes the lotion may be uſed once or twice a-day, and rather weaker than the above proportions; but in inveterate caſes, it is neceſſary to apply it once or twice every hour, and to increaſe its ſtyptic power in proportion; and when the complaint is ſomewhat relieved, the ſtrength of the lotion may be leſſened, and its application be leſs frequent.

"The reaſons for a frequent repetition of the means juſt mentioned, in bad caſes, are, indeed, of the moſt urgent nature. Until the conjunctiva is ſomewhat thinned, and the quantity of the diſcharge diminiſhed, it is impoſſible to know

know in what ſtate the eye is; whether it is more or leſs injured, totally loſt or capable of any relief. The continuance or extinction of the ſight frequently depends on the ſpace of a few hours: nor can we be relieved from the greateſt uncertainty, in theſe reſpects, until the cornea becomes viſible." Ware, p. 145.

This gentleman, with every appearance of reaſon, condemns the uſe of emollient poultices, which muſt have a tendency to increaſe the ſwelling and relaxation of the conjunctiva. If poultices are preferred, he particularly recommends ſuch as poſſeſs a tonic or mild aſtringent property; as one made of the curds of milk, turned with alum, and an equal part of unguentum ſambuci, or axungia porcini. This is to be put on cold, and frequently renewed, without omitting the uſe of the injection. Ware, p. 147.

When the ſecreted matter is glutinous, and makes the eye-lids ſo adherent together, that they cannot be opened, after being ſhut for any length of time, the adheſive matter muſt be ſoftened with a little freſh butter mixed with warm milk, or by means of any other ſoft oleaginous liquor, after the poultice is taken off, and before uſing the lotion. P. 147.

If the everſion of the eye-lids only occurs when the child cries, and then goes off, nothing need be done in addition to the above means. When, however, the everſion is conſtant, the injection muſt be repeated more frequently than in other caſes; the eye-lids put in their natural poſition after its uſe; and an attendant directed to hold on them, with his finger, for ſome length of time, a compreſs dipped in the diluted aqua camphorata. P. 148.

In ſome caſes, when the inſide of the eye-lids has been very much inflamed, the tinctura thebaica, inſinuated between the eye and eye-lids, has been uſeful. If, after the morbid ſecretion is checked, any part of the cornea ſhould be opaque, the unguentum hydrargyri nitrati, melted in a ſpoon, and applied accurately on the ſpeck, with a fine hair pencil; or Janin's ophthalmic ointment, lowered and uſed in the ſame manner; may produce a cure, if the opacity be not of too deep a kind. When the local diſeaſe ſeems to be kept up by a bad habit, alteratives ſhould be exhibited, ſuch as the æthiops mineralis, or ſmall doſes of calomel.

Purulent Ophthalmy in adult Subjects.—There is another kind of purulent ophthalmy to which adults are ſubject, and which is ſo generally repreſented by the beſt modern authors, as ariſing from two very peculiar cauſes, *viz.* the ſuppreſſion of a gonorrhœa, and the inadvertent application of the matter of gonorrhœa to the eyes, that we feel it to be our duty not to paſs over the caſe in ſilence.

The diſeaſe produces rather a ſwelling of the conjunctiva, than of the eye-lids. This tumefaction is quickly followed by a diſcharge of a yellow greeniſh matter, ſimilar to what iſſues from the urethra in caſes of clap. Heat and pain in the eyes, great averſion to light, and, in ſome inſtances, an appearance of hypopium in the anterior chamber, are ſymptoms which accompany the complaint. When the diſorder proceeds from the application of the infectious matter to the eyes, it is alleged to be of a leſs ſevere kind.

With reſpect to the caſe, aſſerted to originate from a ſuppreſſion of a diſcharge from the urethra, the method commonly adopted by ſuch practitioners as place implicit reliance in the aſſigned cauſe, is to inject into the urethra warm oil, introduce bougies, and apply poultices to the perineum, with a view of renewing the diſcharge from the paſſage. However, the rarity of the complaint, upon the ſudden ſtoppage of a gonorrhœa; the poſſibility of an ophthalmy ariſing as well at this, as at any other period, quite independently of the urethral affection; and the fallacious nature of any inference deduced from the ſuppoſed reſemblance of the diſcharge from the eyes to that from the urethra, are circumſtances which cannot fail to raiſe in a diſcerning mind a degree of doubt concerning the reality of the imputed cauſe. Cooper's Firſt Lines of Surgery, p. 316. edit. iii.

The treatment of the purulent ophthalmy in adult ſubjects, from what cauſe ſoever it may ariſe, conſiſts in adopting at firſt antiphlogiſtic means, applying emollient remedies to the eyes, and a bliſter to the temple, or nape of the neck. The eyes may be frequently fomented with a decoction of white poppy-heads, and warm milk may be repeatedly injected beneath the eye-lids. In order to prevent the eye-lids from adhering together, the ſpermaceti cerate may be ſmeared upon the edge of each tarſus every night at bed-time.

When the heat and pain in the eyes, and the febrile ſymptoms are diminiſhed; when an abundant diſcharge of pus has commenced; all topical emollient applications are to be relinquiſhed, and the following collyrium made uſe of: ℞ Aq. roſæ ℥x. Hydrarg. oxymuriatis gr. j. Miſce. Scarpa affirms, that in the ophthalmy originating from the inadvertent communication of gonorrhœal matter to the eyes, applications in the form of ointment, ſuch as Janin's ung. ophthalmicum, or the ung. hydrarg. nitrat., are more efficacious than fluid remedies.

Of the epidemic purulent, or Egyptian Ophthalmy.—The ſpecies of ophthalmy about which we ſhall next offer a few obſervations, has received the laſt of the above appellations, in conſequence of its having been ſuppoſed to reſemble that kind of inflammation of the eyes, which deſtroyed the ſight of a conſiderable number of our ſoldiers in Egypt in the year 1801, or rather in conſequence of the opinion, that it is a peculiar ophthalmy, which was firſt brought from that country into England by the troops which returned from the celebrated Egyptian expedition. Mr. Ware, however, does not approve of calling this ophthalmy *Egyptian*, becauſe, ſays he, an ophthalmy, preciſely ſimilar in its ſymptoms and progreſs, has appeared long ago in this and other countries, and in Egypt, as well as England, ſeveral varieties of ophthalmy prevail. This gentleman prefers naming the epidemic inflammation of the eyes *purulent*, ſince one of its chief ſymptoms, and that which diſtinguiſhes it from every other, is the profuſe diſcharge of a purulent-coloured fluid. This caſe is very different from an ophthalmy, which, at various times, has been epidemic in this and other countries, without any purulent diſcharge from the eyes, which is ſeldom dangerous to ſight, and in a few days generally yields to internal antiphlogiſtic means, and mildly aſtringent applications. Ware on the Epidemical Purulent Ophthalmy, note p. 3. 1808.

Few ſurgeons have ſeen more of this diſtreſſing diſeaſe than Mr. George Peach, ſurgeon to the 9th regiment of light dragoons, and formerly ſurgeon to the 2d battalion of the 52d regiment of foot, a corps in which the Egyptian ophthalmy prevailed in a ſurpriſing degree.

According to this gentleman, the patient complains, in the firſt ſtage of the diſeaſe, of being ſuddenly ſeized with a rolling of ſand in his eye; the veſſels on the albuginea become ſuddenly turgid with blood, and the lower palpebræ very vaſcular. The caſes treated in this recent ſtate generally yield. But, if very active meaſures do not arreſt the progreſs of the diſeaſe, the ſecond ſtage appears, when the palpebræ ſuperiores become much enlarged; the eye-lids can only be opened with extreme difficulty, and then either a ſcalding fluid is diſcharged and excoriates the face,

or a flux of thick yellow matter takes place. In this ſtate, it is frequently in our power to ſtop the progreſs of the evil; but if the moſt decided and active practice be not adopted, the diſeaſe reaches the third ſtage, in which every thing is ſeldom of little avail in relieving the moſt diſtreſſing ſymptoms. The cornea now too often becomes ulcerated, and the eye ruptured.

On the firſt appearance of the diſeaſe, Mr. Peach had recourſe to veneſection, and the antiphlogiſtic treatment. Being unſucceſsful, he tried bark and ſtimulants; but being ſtill more unſucceſsful with this mode of treatment, he reverted to the antiphlogiſtic plan in its fulleſt extent, and with the greateſt ſucceſs, and he found, that he did not formerly ſucceed, becauſe he did not carry this mode far enough. It is in the commencement of the diſeaſe that a very large quantity of blood ſhould be taken away: in that ſtage, large veneſection, even *ad deliquium animi*, is almoſt an infallible remedy. It is not ſufficient to take away twenty or thirty ounces of blood. Mr. Peach has often taken away ſixty, at the ſame time enjoining perfect reſt, the avoidance of all animal food, and putting in practice every other part of the antiphlogiſtic treatment. The complaint is naturally diſpoſed to relapſe, and as often as the diſeaſe, or even the ſlighteſt pain, or uneaſineſs in the eye, returns, ſo often did this gentleman return to the lancet. Such practice, Mr. Peach confeſſes, is likely to excite aſtoniſhment; but the fulleſt trial of it has demonſtrated to him its utility. In many of the caſes, which occurred to him, the progreſs of the inflammation was ſo rapid, that it probably would have totally deſtroyed the eye, if only the ordinary mode of treating ophthalmy had been reſorted to. He adviſes particular attention to be paid to the firſt ſenſation of ſand in the eye: he never defers veneſection, when this is complained of; and the patient, in general, finds ſo much advantage during the operation, that he ſays, "the ſand is removed." Mr. Peach has occaſionally found advantage ariſe from dropping the undiluted aqua litharg. acetat. into the eye, though great pain was the immediate effect of its application. On the whole, however, he concludes, that dropping ſubſtances into the eye is not ſerviceable, and ſays, that, ſince this practice was relinquiſhed, the eye-lids have not been ſo often inverted. The bowels muſt be kept open. Benefit has often been derived from ſhaving the head, and keeping it continually wet with water, or vinegar. Bliſters are alſo ſometimes indicated; but the great reliance is to be put in the ſtricteſt antiphlogiſtic regimen, and copious veneſection. See Edinb. Med. and Sur. Journal, for January, 1807.

With regard to the cauſes of the epidemic purulent ophthalmy, Mr. Ware ſeems to think, that the complaint is moſtly communicated by contact. Some of the worſt caſes of the purulent ophthalmy of children have happened in thoſe, whoſe mothers were ſubject to an acrimonious diſcharge from the vagina at the time of parturition. Some of the worſt forms of the purulent ophthalmy in adults have occurred in thoſe, who, either ſhortly before the attack of the ophthalmy, or, at that very time, laboured either under a gonorrhœa, or a gleet. Mr. Ware does not mean to impute every purulent ophthalmy to ſuch a cauſe; but in the majority of adults whom he has ſeen affected, if the diſorder had not been produced by the application of morbid matter from a diſeaſed eye, it could be traced to a connection between the ophthalmy and diſeaſe of the urethra. Other cauſes, Mr. Ware acknowledges, may contribute to aggravate, and, perhaps, produce the diſorder, and the purulent ophthalmy in Egypt has been attributed to a great number. The combined influence of heat and light, of a burning duſt continually raiſed by the wind, and of the heavy dews of the night, may powerfully tend to excite inflammations of the eyes. Yet ſomething more muſt operate in cauſing the malignant ophthalmy now under conſideration; for the ſame cauſes operate with equal violence in ſome other countries beſides Egypt, and yet do not produce the ſame effect; and in this country, (continues Mr. Ware,) the diſorder prevailed during the laſt ſummer, to as great a degree, and upon as great a number of perſons, within a ſmall diſtrict of leſs than a mile, as it ever did in Egypt; and yet, beyond this ſpace, on either ſide, ſcarcely a perſon was affected with it. The diſorder was certainly brought into this country by the ſoldiers who returned from Egypt, and was probably communicated from them to many others. Now, as the action of the atmoſphere alone cannot account for the ſpreading of the diſeaſe, &c. Mr. Ware is led to believe, that this particular diſorder is only communicable by abſolute contact; that is, by the application of ſome part of the diſcharge, which iſſues, either from the conjunctiva of an affected eye, or from ſome other membrane ſecreting a ſimilar poiſon, to the conjunctiva of the eye of another perſon. In ſchools and nurſeries, in conſequence of children uſing the ſame baſins and towels, as others who had the complaint, the diſeaſe has been communicated to nearly twenty in one academy. Hence, Mr. Ware cenſures the indiſcriminate uſe of thoſe articles in ſchools, nurſeries, hoſpitals, ſhips, and barracks. P. 14, 15.

The principal difference, between the purulent ophthalmy of infants, and that of adults, conſiſts in the different ſtates of the tunica conjunctiva. In the former, notwithſtanding the quantity of matter confined within the lids is often profuſe, the inflammation of the conjunctiva is rarely conſiderable, and whenever the cornea becomes impaired, it is rather owing to the lodgment of ſuch matter on it, than to inflammation. But in the purulent ophthalmy of adults, the diſcharge is always accompanied with a violent inflammation, and generally with a tumefaction of the conjunctiva, by which its membranous appearance is deſtroyed, and the cornea is made to ſeem ſunk in the eye-ball. Ware, p. 23.

We have already detailed the ſucceſsful plan of taking very large quantities of blood from the arm, as practiſed by Mr. Peach. Mr. Ware ſpeaks alſo in favour of bleeding; but has rarely carried it to the extent it has been in the army. In weak perſons, this gentleman prefers, inſtead of repeating veneſection, topical bleeding, either from the vein that paſſes on the ſide of the noſe, or by means of five or ſix leeches put on the temple. Sometimes, he thinks it better to ſcarify the inſide of the lower eye-lid with the point of a lancet, carried along parallel to, and very near the margin of this part. Mr. Ware objects to pricking the eye-lid in an infinite number of places, as very painful, and likely to increaſe the irritation. The lancet never need be applied more than twice, and rarely more than once; and, perhaps, leſs pain will be occaſioned by making the inciſion with the edge, rather than the point of the lancet. After taking away blood, Mr. Ware ſays, a large bliſter on the head, or back, is often uſeful. Anodynes ſhould be given, with occaſional purgatives, and an antiphlogiſtic regimen. Ware on Purulent Ophthalmy, 1808, p. 26, &c.

Dr. Vetch, on the ſubject of local applications in the preſent diſeaſe, adviſes keeping the eyes continually covered with linen, dipt in ſome cooling lotion. In the firſt ſtage, he gives the preference to dropping the aqua ſapphirina into the eye; afterwards, when the ſwelling of the eye-lids has come on, he prefers the aqua litharg. acet. While the patient is ſubject to a recurrence of pain, he thinks the

injection of warm water the beſt application. For the purpoſe of leſſening the ſwelling of the eye-lids, he adviſes compreſſes, dipt in the aqua litharg. acet., to be applied with a moderately firm preſſure. When the ſwelling, and other ſymptoms of the ſecond ſtage have ſubſided, Dr. Vetch recommends more aſtringent applications, ſuch as the aqua lithargyri acet., Bates's camphorated water, ſolutions of alum, and the muriate of mercury. See An Account of the Ophthalmia, as it appeared in England ſince the Return of the Britiſh Army from Egypt; by John Vetch, M.D. 1807; p. 111.

Mr. Ware gives the preference to the aqua camphorata, which is to be uſed exactly in the ſame way, as was deſcribed above, in ſpeaking of the purulent ophthalmy of children. Probably, if army ſurgeons had been careful to inject their applications under the eye-lids, as adviſed by Mr. Ware, great benefit would have been produced. In other ways, the effect of the remedies is often loſt. When the inflammation has been great, Mr. Ware has only put four or five grains, inſtead of eight, of the cuprum vitriolatum to eight ounces of water; and, while the inflammation is great, he would never adviſe more than eight grains to this quantity of water. He uſually employs the lotion cold, eſpecially in children; but in ſome adults, in whom the general fever and local inflammation have been conſiderable, he has been obliged to uſe it warmed. In caſes of great pain and ſwelling, it ſhould be very weak, leſs often applied, and ſometimes only warm water injected. In ſuch circumſtances, Mr. Ware alſo ſanctions fomenting the eye with a flannel, or ſponge, wet with a hot decoction of poppy-heads, or mere hot water. When the cornea threatens to burſt, this gentleman approves of opening it, in order to diſcharge the aqueous humour, by making an inciſion in a place where the ſcar will not obſtruct viſion.

Mr. Wardrop, it is well known, has adviſed puncturing the cornea, and letting out the aqueous humour, in all caſes of ophthalmy attended with ſevere ſymptoms and conſiderable fullneſs of the eye. (See Edinb. Med. and Surg. Journal, for January 1807.) Mr. Ware approves of the ſame proceeding in the epidemic purulent or Egygtian ophthalmy, when antiphlogiſtic, mucous, and aſtringent lotions fail in leſſening the ſymptoms, and in preventing the cornea from becoming opaque; but, eſpecially, if a white rim ſhould begin to be formed at its circumference.

Of Chronic Ophthalmy.—Strictly ſpeaking, every acute ophthalmy has a ſecond ſtage, which is, when compared with the firſt, of a chronic nature. However, in general, when *chronic* ophthalmy is ſpoken of, the diſeaſe is implied, as it appears in a very protracted ſtate.

The ordinary cauſes of chronic ophthalmy are of three kinds. 1. An increaſed irritability continuing in the eye after the acute ſtage of ophthalmy has ſubſided. 2. Another affection of the eye, or of the adjoining parts, of which the chronic ophthalmy is only an effect. 3. Conſtitutional diſeaſe.

1. The firſt kind of caſe requires the internal exhibition of bark and valerian. The patient ſhould take nouriſhing, eaſily digeſtible food; a moderate quantity of wine and gentle exerciſe; and he ſhould reſide in a mild and ſalubrious ſituation. The vapour of the ſpiritus ammoniæ compoſitus ſhould be applied to the eye, through a funnel for half an hour, three or four times a day, and the eye-lids and eyebrows may be rubbed with the linimentum camphoræ.

2. The diſorders in the eye and its vicinity, on which chronic ophthalmy depends as an effect, are conſidered in other articles of the preſent work. See Fistula *Lachrymalis;* Staphyloma; Trichiasis; Ectropium; &c.

We ſhall conclude this ſubject with a few obſervations on chronic ophthalmy connected with conſtitutional diſeaſes.

Scrofulous Ophthalmy.—According to the poſthumous work of Mr. Saunders, puſtules of the conjunctiva, aggregated at the margin of the cornea, or appearing ſeparately, or ſucceſſively over any part of its ſurface, conſtitute a ſpecific character of ſtrumous ophthalmy, with which the morbid appearances, peculiar to a ſcrofulous conſtitution, are in various degrees connected. In large cities, the cauſes are ſtated to be an impure atmoſphere, improper food, and cold.

No ſpecific for ſcrofula being known, the treatment rather conſiſts in preventing an aggravation, than attempting the radical cure of the complaint. Every thing debilitating is injurious; as evacuations, indigeſtible food, intenſe ſtudy, a ſedentary life, damp marſhy reſidences, lowneſs of ſpirits, frequent tranſitions from heat to cold. On the other hand, keeping the bowels in a regular ſtate with ſmall doſes of the tartras potaſſæ, antimonium tartarizatum, or rhubarb, and the exhibition of bark, to which may be occaſionally added the tinctura guaiaci ammoniata, are particularly proper. The æthiops mineralis may be advantageouſly given from gr. ſs to gr. xx daily for the ſpace of three weeks. Scarpa alſo recommends the aqua calcis to be taken in broth for ſeveral months, and ſea-bathing, and friction of the body with a fleſh-bruſh.

With regard to topical remedies, ſoft relaxing applications prove hurtful; but ſlightly aſtringent collyria, the tinctura thebaica, and the unguentum tutiæ, are advantageous applications. All coverings muſt be removed from the eyes, except a ſhade of green ſilk.

Scrofula often diſappears ſpontaneouſly as children approach the adult ſtate, and, with it, this affection of the eyes.

Upon the treatment of ſcrofulous ophthalmy, the publication of the late Mr. Saunders affords no very remarkable information. Mild caſes are ſaid to yield to a purer atmoſphere, and a few doſes of the hydrargri ſubmurias and rhubarb; but too frequent a repetition of the firſt of theſe medicines is condemned. When the inflammation is not acute, and the ulcers are indiſpoſed to heal, we are adviſed to inject on them a ſolution of nitrate of ſilver, two grains to an ounce of diſtilled water. But when more lymph is effuſed round the ulcer than is neceſſary for the healing proceſs, general, or topical bleeding, and more frequent purging, are ſanctioned. In this ſtate, every ſtimulant application is forbidden, and we are recommended to employ either a weak ſaturnine lotion cold, or elſe a warm decoction of poppies.

Venereal Ophthalmy.—In no ſubject do ſurgical writers betray leſs conſiſtency than in the preſent. Many have doubted the reality of ſyphilitic ophthalmy; others have admitted its occurrence, but left it undeſcribed. Scarpa ſays it is peculiar in not betraying manifeſt ſigns of inflammation, ſtealing on clandeſtinely without much uneaſineſs. It afterwards relaxes the veſſels of the conjunctiva and lining of the eye-lids, and alters the ſecretion of Meibomius's glands. Ulceration of the margin of the eye-lids is cauſed, the eyelaſhes fall off, and the cornea becomes opaque. In the worſt ſtage, the malady excites an itching in the eyes, that is exaſperated at night, and diminiſhes towards the morning.

It is obſerved by Mr. Pearſon, that, in that form of the ſecondary ſymptoms of ſyphilis, where the ſkin is the part chiefly affected, a diſeaſe reſembling the ophthalmia tarſi ſometimes makes its appearance. It is not commonly attended with much redneſs of the tunica conjunctiva; nor is the ſenſibility of the eye to light remarkably increaſed; yet

this gentleman has ſeen the complaint, in a few inſtances, under the form of an acute ophthalmy, reſiſting all the common modes of treatment, but yielding immediately to a courſe of mercury.

According to Mr. Pearſon, the venereal ophthalmy reſembles in its appearance ſuch diſeaſes of the tarſi and conjunctiva as are derived from ſcrofula; and, in his belief, there are no ſpecific characters by which diſeaſes of the eye or eyelids, produced by the action of the venereal virus, can be diſtinguiſhed from thoſe which are excited by other cauſes. See Tranſ. of Scarpa on Diſeaſes of the Eyes, by Briggs, note, p. 187.

In the poſthumous work of Mr. Saunders, ſyphilitic inflammation of the iris is ſtated to differ from common inflammation of that part in the following circumſtances: the iris is much more thickened and puckered, the texture appears more changed, the irritation on expoſure to light is leſs, the pain is moſt intenſe at night, and red veſſels are ſooner ſeen in the ſubſtance of the iris. The pupil is not ſo much contracted as in a caſe of ſimple inflammation; and although the general appearance of diſeaſe is greater, the pain is actually leſs. The blindneſs is often total. When ſyphilis affects the other tunics of the eye, as well as the iris, the eye-ball is ſaid to appear full, the patient is ſlightly incommoded by preſſure on the organ, and the ſenſibility of the retina is impaired, and, in ſome inſtances, deſtroyed. In the worſt ſtage, the pupil is repreſented as becoming irregular and dilated; while the iris and cornea are in contact, and much diminiſhed and obſcured; the ſclerotica is tumid and uneven on its ſurface; and much head-ache prevails. Saunders's Treatiſe on ſome practical Points relating to Diſeaſes of the Eye, &c. p. 64 and 67.

Mercurial friction, together with the decoct. ſarſaparillæ et mezerei, are recommended. A few drops of a collyrium, containing the hydrargyrus muriatus, are alſo directed to be introduced under the eye-lids every two hours. At night the eye-lids may be ſmeared with Janin's ointment, or the unguentum hydrargyri nitrati. Mr. Saunders appears to have cured venereal ophthalmies, by exhibiting calomel very freely. In one caſe he gave eight grains a day for a fortnight; and in another, two grains were ordered to be taken every five hours, with half a grain of opium. The ſame diſtinguiſhed oculiſt alſo ſometimes took blood from the temporal arteries.

The works to which we are chiefly indebted for the preceding obſervations, are Richter's Anfangſgrunde der Wundarzneykunſt, band 3. kap. 1. Ware on Ophthalmy, Pſorophthalmy, &c. Alſo on the Epidemic Purulent Ophthalmy. S. Cooper's Dictionary of Practical Surgery, edit. 2; and Firſt Lines of the Practice of Surgery, edit. 3. Saunders's Treatiſe on ſome practical Points relating to Diſeaſes of the Eye; and Scarpa's Oſſervaz. ſulle Principali Malattie degli Occhi, capo 7.

In the foregoing article, the reader may have expected a few remarks on common contuſions of the eye; but the nature and treatment of theſe caſes are ſo familiarly known to every body in the preſent flouriſhing condition of the art of pugiliſm, that we conſider it almoſt ſuperfluous to ſay any thing here upon the ſubject. The moſt ſucceſsful plan of preventing and leſſening the diſcolouration attending what is termed a *black eye*, is to bathe the contuſed part, as ſoon after the receipt of the blow as poſſible, with the aqua ammoniæ acetatis, or common vinegar. Linen may be wet with either of theſe applications, and kept conſtantly upon the bruiſe, care being taken to dip the rag frequently in the lotion, ſo that it may always be wet and cool. Beſides this common means, it will be proper in ſevere caſes to purge the patient, and even to uſe leeches, and practiſe veneſection.

OPIATE, Opiatum, in *Medicine*, is ſometimes applied to any confection or electuary.

In which ſenſe it is defined an internal remedy, variouſly compoſed of powders, pulps, liquors, ſugar, or honey, reduced into a ſoft conſiſtence.

The opiate of Solomon was formerly a compoſition of great fame, ſo called from one Solomon, a phyſician, its inventor; and firſt publiſhed by Lawrence Joubert

There is a particular kind of opiates, called *incarnatives*, for the teeth and gums, made of alum, ſumach, lignum aloes, myrrh, maſtic, &c. reduced into powder.

Opiate is alſo uſed for any medicine given with an intention to procure ſleep.

In which ſenſe the word is of the ſame import with *narcotic*, *hypnotic*, *ſoporific*, or *pacific*.

Opiate is more particularly uſed for a compoſition wherein opium is an ingredient. See Opium.

OPIE, John, in *Biography*, our late profeſſor of painting in the Royal Academy, was born in May, 1761, at St. Agnes, in Cornwall, a village about ſeven miles diſtant from the town of Truro. His father was a maſter carpenter, and principally engaged in ſupplying the mines in that neighbourhood with ſuch conſtructions of timber as they required, either for working or for ſupport.

Few men have attained to eminence by a more irregular courſe of ſtudy, by ſtronger native endowments, or by more determined induſtry, than Opie. He was very remarkable for the ſtrength of his underſtanding, and the rapidity with which he acquired all the learning that a village ſchool could afford him. When ten years old, he was not only able to ſolve ſeveral difficult problems in Euclid, but was thought capable of inſtructing others: and when he had ſcarcely reached his twelfth year, he eſtabliſhed an evening ſchool in St. Agnes, and taught writing and arithmetic; reckoning among his pupils ſome who were already twice his age.

His father was very ſolicitous to bring him up in his own buſineſs, and to this end bound him apprentice to himſelf. But the drudgery of a laborious employment was by no means ſuitable to one whoſe mind had attained ſome glimpſes of ſcience, and ſtill more of art. From his tenth year he had practiſed drawing, and even painting, in a rude way; and took every opportunity, which his confined ſituation afforded, of contemplating prints and pictures; though without any ſyſtem or intention of purſuing the art profeſſionally. So ardent was he in the love of it, that he is ſaid to have neglected his labour, when in houſes where any picture caught his attention, and, in ſome inſtances, carried away ſo much of the works he ſaw in his remembrance, as to have made tolerable good imitations of them at home.

At laſt his father, who ſtrenuouſly endeavoured to controul his inclinations, gave way to his determined perſeverance.

He had already exhibited the ſuperior endowments of his mind, and hung his father's houſe with portraits of his family and friends, when by accident he became acquainted with Dr. Wolcot, then reſiding at Truro, and ſince ſo celebrated under the title of Peter Pindar; who having himſelf a taſte for drawing, and a ſtrong perception of character, ſaw the worth of our artiſt, and was well fitted to afford him inſtruction in many requiſite points.

The patron was proud of his pupil, and aſſiſted and recommended him ſo effectually, that he commenced profeſſed portrait painter, and went about to the neighbouring towns with letters of introduction to the principal families reſident in them, and henceforward entirely ſupported himſelf by his own exertions.

A

At length, in 1781, he came to London, ſtill under the auſpices of Dr. Wolcot, whoſe powerful pen was not ſilent in his cauſe; and the Corniſh boy, juſt ſprung from a tin-mine, and practiſing the difficult art of painting in a forcible manner, and in an original and untutored ſtyle, was the theme of wide-ſpread reputation. By the intervention of Mrs. Boſcawen, to whom the doctor mentioned the talents of Opie, his works became the theme of faſhionable converſation, and he was ſoon almoſt overwhelmed with ſolicitations for portraits by perſons of the higheſt diſtinction; who, caught by the novelty, and ſtruck with the force of his repreſentations, preſſed upon each other to be firſt in his ſtudy, and inſure the exertions of his talents in their favour.

But in little leſs than a twelvemonth, the novelty ceaſing, and thoſe talents being more ſolid than ſhowy, fitted more to gratify the ſenſible than pleaſe the vain, this burſt of occupation ceaſed. It was found that the engaging graces and the enchanting ſmiles of the ladies were not taſtefully diſplayed; or due dignity and conſequence given to the gentleman: and a regard to truth, ſimple and unadorned, not being the guide to judgment with the many, Opie was left for a while, almoſt as if he had never been known, to ſcramble his way onward, as chance or the happy exerciſe of his powers might aſſiſt and direct him.

But he was not a man to be overcome by ſuch a change of circumſtances, and perhaps it was fortunate for his reputation that it was experienced by him. Being gifted by nature with the moſt reſolute induſtry and perſeverance, he was determined not the leſs to merit a continuance of the ſucceſs he had enjoyed; and employed the time now left upon his hands in attempts at compoſition of ruſtic ſubjects, and in more regular hiſtorical painting.

By the eſtabliſhment of the Shakſpeare Gallery in 1786, Opie was firſt fully made known to the public; the latent powers of his mind were there called forth, and what he wanted of academical and claſſical information, he compenſated for, in great meaſure, by character, by force, and by a bold imitation of nature in individual parts. For this gallery he painted five large pictures, of which the fineſt was from the Winter's Tale; Leontes adminiſtering the oath to Antigonus to take charge of the child. But he produced, about the ſame time, a work of far more excellent quality in effect and colour, *viz.* the aſſaſſination of James I. of Scotland, now in the Common Council room at Guildhall; a work which, for hue and colour, challenges competition with the beſt, and is wrought with the greateſt boldneſs and force.

The ſpirit of commerce having been ſucceſsfully exerted, by employing hiſtoric art in the illuſtration of our great dramatic author, other ſpeculations upon the ſame principle were ſoon entered upon: Macklin adopted the bible as the baſis on which to form a gallery of pictures; and Bowyer, the Engliſh hiſtorian Hume; and both were happy to avail themſelves of the talents ſo powerfully exhibited by Opie, who painted many pictures for each of theſe inſtitutions with varied ſucceſs.

Of Opie's ſtyle, the more engaging characteriſtics are breadth, ſimplicity, and force; its defects are want of grace and variety of invention; and of elegance and refinement in expreſſion and execution. The objects of his choice were among the ſtriking and terrible, rather than the agreeable and beautiful; and the materials he introduced were more accordant to his ideas of the pictureſque than the proper. He frequently violated coſtume, not for want of knowledge ſo much as from an inſatiable deſire of contraſt; and ſometimes from conveniency. His taſte lay in the repreſentation of natural objects with ſtrong effect, he therefore made uſe of armour, or of draperies which he had in his ſtudy, and, like Rembrandt, adopted them as his antiques, and uſed them according as he felt they would beſt promote his immediate end. Theſe defects are redeemed, to the well informed eye, by the abſolute truth of imitation in which they are wrought, by the expreſſion of his heads, particularly of old men, or of ſtrongly marked characters, which are exceedingly impreſſive, by the energetic actions of his principal figures, by the broad and daring execution of his pencil, and by the magic force of his chiaro-ſcuro. In the latter point no artiſt ever excelled him. His figures project from the canvas in ſome of his beſt works; and if ſeen under favourable circumſtances, would be abſolutely illuſive.

When the tide of hiſtoric commiſſions ſubſided, Opie employed himſelf in repreſenting ſcenes of common life, as well as in portraits. Cottage viſits, an old ſoldier at an ale-houſe door, fortune-tellers, and that claſs of materials which the Dutch and Flemiſh maſters have recommended by high finiſh and convenient neatneſs of ſize, he painted upon a large ſcale. The reputation ſo juſtly due to his talents had now become ſteadily attached to him, and he had no longer to complain of the unfeeling caprice of faſhion, for he enjoyed an uninterrupted ſource of employment, in portraiture at leaſt, till his death, and generally diſpoſed of the fancy pictures with which he choſe to interſperſe his labours. Theſe were very numerous, for he was exceedingly induſtrious, and his principal delight was in the practice of his profeſſion.

His portraits are well worthy of eſteem, from the complete individuality which characteriſes them, without being marked with trifling peculiarities. They are calculated to gratify the ſenſible and judicious, who prefer a direct appeal to the underſtanding, over a more alluring inſinuation by the medium of taſte; which, while it pleaſes the eye, too frequently ſacrifices ſomewhat of truth. Yet they are often gracefully as well as powerfully marked. Thoſe who recollect the portrait of H. Treſham, R. A. (exhibited in 1806, and now in the poſſeſſion of lord Cawdor,) will acknowledge the truth of this remark, while in that of Mr. Holcroft, (exhibited at the ſame time,) they beheld the great extent of his power in preciſe and poſitive, but determined and bold, imitation of feature and character.

Opie having been admitted an aſſociate of the Royal Academy in 1786, and an academician in the year following, upon the diſmiſſal of Mr. Barry from the body, aſpired to the honour of being profeſſor of painting, but reſigned his pretenſions in favour of Mr. Fuſeli, who was choſen. When that gentleman was appointed to the ſtation of keeper in 1805, he again advanced his claim, and was unanimouſly received. He had previouſly tried his power in literary compoſition, with no ſlight degree of ſucceſs; firſt in the life of ſir J. Reynolds, in Dr. Wolcot's edition of Pilkington's dictionary, and again in the publication of a plan for the formation of a national gallery, "tending at once to exalt the arts of his country and immortalize its glories." He afterwards, in 1804, read two lectures on painting at the Royal Inſtitution, which were fraught with inſtructions, and were received with applauſe; though it has been obſerved by a judicious critic, that the ſtyle in which they were compoſed was "abrupt, crowded, and frequently unmethodical; rather ruſhing forward himſelf, than leading his auditors to the ſubject." Nevertheleſs, his exertions on this occaſion drew upon him reſpect, the more perhaps as he was not generally known to be a man fond of literature; and the world were the more ſurpriſed to hear refined ſentiments in eaſy and even elegant language, from one who was not unfrequently

repreſented

represented as coarse and vulgar in mind and manner. In fact, Opie by no means merited such an unfavourable report; he was plain and unaffected, and spoke his mind freely; was manly and energetic, yielding little to folly or caprice, and by no means adapted to gratify the vain and ignorant; but he was not wilfully offensive, and condemned warmly those who were so.

He possessed a tenacious memory, and readily quoted in conversation the authors he had read, particularly the poets, and was a playful and entertaining companion when he found his company agreeable to him, capable of enjoying his humour, of benefiting by his information, or of eliciting reflection in his own mind; and it was seldom that a thinking man could be in his society without feeling roused by his energy.

The lectures which he delivered at the Royal Academy are published to the world, it is therefore not necessary to enter upon their merits; but it will be justice to their author, earnestly to recommend the perusal of them to all who wish to understand the principles of the art on which they treat. Unhappily the course was incomplete, as he only gave four lectures of the six prescribed to each professor. The world were deprived of all further benefit from his powerful intellects by his death, which occurred, after a lingering illness, in April 1807. He was honoured by an interment in St. Paul's cathedral, near the grave of sir Joshua Reynolds, and his funeral was most respectably attended by almost all the members of the Royal Academy, and many of the nobility and gentry of the country.

OPILIO, in *Natural History*, a species of *Phalangium*; which see.

OPIMATORES, among the Romans, military men, who had the direction and management of the provisions, and were to take care that the army wanted nothing.

OPINION, Opinio, denotes a probable belief; or a doubtful and uncertain judgment of the mind.

Opinion is better defined the assent of the mind to propositions not evidently true at first sight; nor deduced, by necessary consequence, from others that are so; but such as carry the face of truth.

The schools define opinion, *assensus intellectus cum formidine de oppositο*; an assent of the understanding, with some fear or distrust of the contrary being true.

According to logicians, demonstration begets science, or knowledge; and probable arguments beget opinion.

Wherever the mind's acquiescence in a truth proposed to it is accompanied with any doubt, this is what we call an opinion, and it is the result of obscure and indeterminate perception. That the planets revolve about the sun is a branch of knowledge: that they are inhabited by beings similar to men is only an opinion. Hence, knowledge is said to be certain, opinion uncertain. Of opinions, some are probable and others improbable. A probable opinion is one, the evidence of the truth of which preponderates over that of its falsehood: and an improbable opinion is that, the evidence of whose falsehood preponderates over that of its truth.

Plato makes opinion a medium between knowledge and ignorance; clearer and more express than ignorance, yet more obscure and unsatisfying than knowledge.

OPISTHODOMUS, οπισθοδομος, among the *Athenians*, the public treasury, so called from its being situated on the backside of Minerva's temple. Here, besides other public money, a thousand talents were laid in store, against any very urgent occasion; but if any man expended them upon a trivial account, he was to be put to death. Also the names of all that were indebted to the commonwealth were entered in a register in this place. The tutelar gods of this treasury, were Jupiter Σωτηρ, or the Saviour, and Plutus, the god of riches, whom they represented with wings, and placed next to the statue of Jupiter the Saviour; which was unusual in other places.

OPISTHOGRAPHUM, οπισθογραφον, among the *Ancients*, a waste-book, or schedule, on which were writ extemporary things that wanted to be revised and corrected afterwards.

The word is compounded of οπισθεν, *i. e. afterwards*, or *on the backside*, and γραφω, *I write*; because it was writ over again on the backside of every page, which was left blank for that purpose.

OPISTHOTONOS, from οπισθεν, *backward*, and τονος, from τεινω, *to extend*, in *Surgery*, that species of tetanus, in which the head and trunk are drawn backward by the muscles. See Tetanus.

OPIUM, in *Chemistry* and *Medicine*. Several vegetables furnish a milky fluid, which, when reduced to a proper consistency, may have similar properties to opium properly so called. Of these are the lactuca virosa, or the wild lettuce, as well as the garden lettuce. But it is furnished in the greatest abundance from the white poppy of the East, (papaver somniferum,) and also, in small quantity, from the other species of the poppy.

The white poppy is cultivated to great extent in Turkey, for the purpose of affording opium. After the flowering of the plant, when the capsule containing the seed has arrived at its full growth, slight longitudinal incisions are made in the capsules towards the evening. A milky juice oozes out, which is collected the next day. The excess of moisture being evaporated in the sun, it assumes the consistency fitted for making it into cakes, in which state it is found in commerce. This is generally called *Turkey* opium, to distinguish it from another kind brought from the East Indies, and known by the name of *East Indian* opium. This is generally softer than the Turkey, of a darker colour, less bitter, and more disagreeable to the taste, and has a disagreeable empyreumatic smell. It is not so strong as the Turkey, but considerably cheaper. When opium is soft and friable, of a blackish colour, and has an empyreumatic smell, it is bad. Its taste should be bitter but not sweet.

Opium softens with heat so as to adhere to the fingers, but it does not fuse. When it is reduced to powder, and ground into a pulp with alcohol or water, and an extra quantity of fluid added, the greatest part of it will dissolve by boiling it for some time, a great part of which is deposited on cooling. We have already given the means of separating a peculiar substance from opium, under the article Narcotic *Principle*; which see.

Both alcohol and water, therefore, appear to dissolve the principal part of opium, but the alcoholic solution is generally used in medicine.

The aqueous solution is rather less coloured than that with spirit. It has also less smell and taste. It affords a precipitate with carbonate of potash, with the muriates and nitrates of mercury, with acetate of lead, nitrate of silver, and a brown precipitate with the red sulphate of iron. Infusion of galls affords a precipitate with opium. In triturating opium to mix it with water, a glutinous or rather waxy substance adheres to the bottom of the mortar, which does not mix with the liquid. This is the insoluble part of opium.

From what is stated here and under the article Narcotic *Principle*, it will appear that opium principally consists of three substances, namely, the *narcotic principle*, to which it owes its property of lessening the sensibility of the system; of a resin, to which it owes its stimulating virtues, and its great inflammability; and the oxygenated extract, to which may be

be attributed its aſtringent qualities. It is no doubt on this account that medical men have differed ſo much as to its being a ſedative or a ſtimulant. Moſt of them agree that the ſedative effects which reſult from it, are greater than could reſult from the ſtimulus previouſly afforded. It is hoped that ſome ingenious experimenter will clear theſe anomalies by new reſearches. See NARCOTIC *Principle.*

OPIUM, formed from οπος, *juice*, in *Pharmacy*, &c. a narcotic, gummy-reſinous milky juice, drawn from the heads or capſules of the white poppy, more eſpecially abounding in the cortical part of the capſules, and afterwards inſpiſſated. The capſules are powerfully narcotic, and anodyne; boiled in water they impart to the water their narcotic juice, together with other juices which they have in common with vegetable matters in general. The liquor, ſtrongly preſſed out, ſuffered to ſettle, clarified with whites of eggs, and evaporated to a due conſiſtence, yields an extract which is about one-fifth or one-ſixth of the weight of the heads. Thus poſſeſſes the virtues of opium, but muſt be given in double its doſe to anſwer the ſame intention, which it is ſaid to perform without occaſioning a nauſea and giddineſs, the uſual effects of opium. This extract was firſt recommended by Mr. Arnot (Med. Eſſ. and Obſ. Edinb. vol. v. p. 108.); and a ſimilar one is now received in the Edinburgh pharmacopeia. It is found very convenient to prepare the ſyrup from this extract, by diſſolving one dram in two and a half pounds of ſimple ſyrup. The "ſyrupus papaveris albi," as directed by both colleges, is a uſeful anodyne, and often ſucceeds in procuring ſleep, where opium fails: it is more eſpecially adapted to children. White poppy heads are alſo uſed externally in fomentations, either alone, or more frequently added to the "decoctum pro fomento."

When the juice flows of itſelf, through inciſions made in the poppy heads, it is properly called *opium.* When drawn by expreſſion, it ought rather to be called *meconium.* The difference between the qualities and virtues of the two juices is very conſiderable. The former is preferable on all accounts, but it is exceedingly rare; the Turks, among whom it is produced, and who make great uſe of it, never allow it to be exported. So that it is the latter that is ordinarily uſed among us, and ſold for opium.

Kæmpfer relates, that the heads, when almoſt ripe, are wounded with a five-edged inſtrument, by which as many parallel inciſions are made at once from top to bottom; that the juice which exudes is next day ſcraped off, and the other ſide of the head wounded in like manner; and that the juice is afterwards worked with a little water, till it acquires the conſiſtence, tenacity, and brightneſs of the fineſt pitch.

The moſt circumſtantial detail of the culture of the poppy, and of the method of procuring the opium from it, is that given by Mr. Kerr, as practiſed in the province of Bahar: he ſays, "the field being well prepared by the plough and harrow, and reduced to an exact level ſuperficies, is then divided into quadrangular areas of ſeven feet long, and five feet in breadth, leaving two feet of interval, which is raiſed five or ſix inches, and excavated into an aqueduct for conveying water to every area, for which purpoſe they have a well in every cultivated field. The ſeeds are ſown in October or November. The plants are allowed to grow ſix or eight inches diſtant from each other, and are plentifully ſupplied with water. When the young plants are ſix or eight inches high, they are watered more ſparingly, but the cultivator ſtrews all over the areas a nutrient compoſt, of aſhes, human excrements, cow-dung, and a large portion of nitrous earth, ſcraped from the highways and old mud-walls. When the plants are nigh flowering, they are watered profuſely to increaſe the juice. When the capſules are half grown, no more water is given, and they begin to collect the opium. At ſun-ſet they make two longitudinal double inciſions upon each half-ripe capſule, paſſing from below upwards, and taking care not to penetrate the internal cavity of the capſule. The inciſions are repeated every evening, until each capſule has received ſix or eight wounds; they are then allowed to ripen their ſeeds. The ripe capſules afford little or no juice. If the wound was made in the heat of the day, a cicatrix would be too ſoon formed. The night-dews, by their moiſture, favour the exſtillation of the juice.

"Early in the morning, old women, boys, and girls, collect the juice by ſcraping it off the wounds with a ſmall iron ſcoop, and depoſit the whole in an earthen pot, where it is worked by the hand in the open ſunſhine, until it becomes of a conſiderable ſpiſſitude. It is then formed into cakes of a globular ſhape, and about four pounds in weight, and laid into little earthen baſins, to be further exſiccated. Theſe cakes are covered over with the poppy or tobacco-leaves, and dried until they are fit for ſale. Opium is frequently adulterated with cow-dung, the extract of the poppy plant procured by boiling, and various other ſubſtances, which they keep in ſecreſy. Opium is here a conſiderable branch of commerce. There are about 600,000 pounds of it annually exported from the Ganges." Med. Obſ. and Inq. vol. v. p 317.

Opium is imported into Europe from Perſia, Arabia, and other warm regions of Aſia. It is brought into this country in cheſts from Turkey and India. The *Turkey opium* is in flat pieces, covered with leaves, and the reddiſh capſules of ſome ſpecies of rumex, which is conſidered as an indication of its goodneſs, as the inferior kinds of opium have none of theſe capſules adhering to them. This opium generally contains about $\frac{1}{4}$th part of impurities. *Eaſt Indian opium* is in round maſſes, covered with ſucceſſive layers of leaves, to the thickneſs nearly of $\frac{1}{4}$th of an inch.

Dr. Charles Alſton, profeſſor of botany and the materia medica in the univerſity of Edinburgh, has given us a diſſertation on opium in the medical eſſays of that place, vol. v. art. 12. This gentleman is of opinion, that notwithſtanding the authorities of Lemery, Savary, Monſieur de la Condamine, in the Mem. de l'Acad. des Sciences for 1732, all which would lead us to conclude we have nothing but the meconium, or the expreſſed juice or decoction of the plant, our opium is neither an extract, nor an inſpiſſated expreſſed juice of poppies, but the milky juice drawn by inciſion from poppy heads. To ſhew this, the doctor, according to the directions of Dioſcorides, on a dry day, before noon, cut off the crown of white poppy heads, ſo as to avoid penetrating into the cavity of the fruit, and collected the milk with a ſilver ſpoon in a china cup. The juice being expoſed to the open air, in a few days thickened to the conſiſtence of opium, and was of a fiery, hot, bitter taſte, and ſoporiferous ſmell, and more ſo than the common opium, of a dark yellowiſh-brown colour on the outſide, ſomewhat higher within, and appeared as if compoſed of drops; after ten years keeping, its colour and taſte remained. This agreed with the account Bellonius, lib. iii. obſ. 15. gives of the beſt opium. That which was gathered from the papaver vulgare, or wild poppy, was ſomewhat of a lighter colour; but Dr. Alſton thinks this but accidental, as the milk ſoon turns black on the knife. He alſo ſlightly ſcarified ſome poppy heads, after the Perſian manner. When the juice was thickened, he ſcraped off the opium, and obtained more of it than by the other method. To procure the tear in its utmoſt perfection, he cut off the ſtar from ſeveral heads, and bending them down let the milk drop

drop into a cup. It grew ſolid as opium, and being formed into a lump, appeared uniformly white; nor was there any difference in the juice of different poppies.

Secondly, the doctor obſerves, that the extract and inſpiſſated juice ſcarce any where reſemble opium; nor is their taſte and ſmell like it. The extract appears black when dried, and ſo does the juice, but when diluted, the firſt is brown and the latter green. The extract is tough and adheſive, the juice rough and friable, and grows mouldy a day or two after expreſſion. Opium may poſſibly be mixed with either of theſe; and the greeniſh-brown opium may have ſome ſmall portion of the juice in it. Its penetrating ſmell is certainly owing to the mixture of ſome aromatic ſubſtance.

Thirdly, opium contains more reſin than either the inſpiſſated juice or extract. One-third of opium appears to be reſin, while the juice and extract ſcarcely yield one-tenth part.

Fourthly, if opium was not the tear of the poppy, there would be no occaſion for ſowing ſo many fields with poppies in Egypt, and other places. Nor would it be ſo powerful a medicine, for its anodyne virtues depend chiefly on the milky juice.

It is a popular error that there is any ſuch thing as white opium; for though the juice, as it runs from the heads of the poppies, be of a milk-colour, it always becomes of a very deep brown as it thickens. Wherever it is found yellowiſh or ſoft, it is a ſign that the juice has not had fire enough.

Moſt of the opium ſold at Conſtantinople is brought from Anatolia, from a place called, by the Turks, Aphium Carahiſſat, *i. e.* Black Caule of Opium. It is alſo produced in the territory of Thebes, in Egypt, whence the beſt opium was formerly called *Thebaic* opium: this differs from the *meconium*, which was made by the ancients of the expreſſed juice or decoction of the poppy, and which they juſtly deemed the "meconium multum opio ignavius."

Opium, according to the experiments of Dr. Alſton, conſiſts of five parts in twelve of gum, four of reſin, and three of earth, or other impurities, not diſſolvable either in watery or ſpirituous menſtruums. From theſe laſt it is purified, in the ſhops, by ſoftening the opium with boiling water, in the proportion of a pint to a pound, into the conſiſtence of a pulp, with care to prevent its burning; and whilſt it remains quite hot, ſtrongly preſſing it from the fæces through a linen cloth; the ſtrained opium is then inſpiſſated in a water-bath, or other gentle heat, to its original conſiſtence. When thus ſoftened with a ſmall quantity of water, the gummy and reſinous parts paſs the ſtrainer together; whereas, if diſſolved by a larger quantity, they would ſeparate from one another. Suppoſing that the reſin of opium is as good, or as much wanted as the gum, or the mucilaginous part, brandy will be found the beſt menſtruum.

The moſt active principles of opium are very fixed; for it keeps well, and, when forty years old, remains hard, ſolid, and retains its taſte: and it ſeems that the practice of roaſting opium, in order to correct it, by diveſting it of its narcotic part, is of no ſervice; and many other proceſſes have been propoſed for correcting the ill qualities which opium is ſuppoſed to poſſeſs, beſides roaſting it; ſuch as fermentation, long-continued digeſtions or boiling, and repeated diſſolutions and diſtillations. Theſe proceſſes, ſays Dr. Lewis, do not promiſe any ſingular advantage: and he adds, that diminiſhing the doſe of opium is a more certain way of leſſening its effects. Alkaline ſalts, he ſays, diminiſh the ſoporific virtue of the opium; fixed alkalies render it diuretic, while volatile ones determine its action to the cutaneous pores; and acids almoſt entirely deſtroy its force.

Upon a chemical analyſis, opium yields phlegm, urinous ſpirit, oil, a volatile and a fixed ſalt, and ſome earth; but little of the virtues of opium can be inveſtigated, or explained, from its analyſis, ſince ſimples, extremely different as to their effects on human bodies, afford the ſame principles on diſtillation, as Homberg has ſhewn by the analyſis of the deadly nightſhade, and cabbage. See Mem. de l'Acad. des Sciences, an. 1701.

The curious may find the analyſis of opium in the above mentioned diſſertation by Dr. Alſton.

Opium is regarded as bad when it is very ſoft or friable, of an intenſely black colour, or when mixed with many impurities. A weak or empyreumatic odour, ſweetiſh taſte, or the power of marking, when drawn acroſs paper, a brown continuous ſtreak, are alſo indications of inferior opium.

Turkey opium has a peculiar, ſtrong, heavy, narcotic odour, and a bitter taſte, accompanied with a ſenſation of acrid heat, a biting on the tongue and lips, if it be well chewed. Its colour, when good, is dark reddiſh-brown, and its texture compact and uniform. When ſoft, it is tenacious; but when long expoſed to the air, it becomes hard, breaks with an uniform, ſhining fracture, is pulverulent, and affords a yellowiſh powder. It is inflammable, and partially ſoluble in water, alcohol, and ether. By long boiling in water under expoſure to the air, its narcotic powers are impaired; yet nothing riſes with water, when it is diſtilled with that fluid: though Beaumé aſſerts, that the odorous part of the opium is an oil. When carefully triturated with hot water, about five parts in twelve of the opium are diſſolved and retained in ſolution, nearly ſix parts are ſimply ſuſpended, and rather more than one part remains perfectly inſoluble, of a viſcid, plaſtic nature, ſomewhat reſembling the gluten of wheat, but of a dark colour. This was regarded by Bucholz as caoutchouc; according to Prouſt, it contains wax; and Gren ſuppoſed it to be analogous to gluten. Mr. Thomſon (London Diſpenſatory) ſays, that by diſſolving alcohol on this ſubſtance, he found a ſmall portion of it diſſolved, acquiring a reddiſh-yellow colour, and becoming milky when added to water. Sulphuric ether, digeſted upon it, broke it down, and diſſolved a portion of it, forming a yellowiſh tincture, which when evaporated in water left reſin, a bitter extractive, and ſome acicular cryſtals of that ſalt, which Deroſné ſuppoſed to be the narcotic principle. The inſoluble part, after the action of the ether, was ſubjected to a ſet of comparative experiments with the gluten of wheat, when it afforded ſimilar reſults with the majority of the teſts employed. Hence, this part of Turkey opium appears to be a modification of gluten combined with reſin, extractive, and a peculiar ſalt.

Eaſt Indian opium has a ſtrong empyreumatic ſmell, and leſs of the peculiar narcotic heavy odour of the Turkey opium; the taſte is equally bitter, but more nauſeous, and it has leſs acrimony: it agrees with the Turkey opium in its other ſenſible qualities, except that its colour is blacker, and its texture leſs compact; and when triturated with water no inſoluble plaſtic reſiduum is left, but it is altogether taken up; eight parts in twelve being diſſolved, and the remainder ſuſpended in the fluid.

The aqueous ſolutions of both kinds of opium are tranſparent when filtered, that of the Eaſt Indian ſort having the deepeſt brown colour; neither is decompoſed by alcohol, but both are precipitated by the carbonate of potaſh, although the pure alkali does not affect them; they are alſo precipitated by ſolutions of the muriate and nitrate of mer-

cury, the acetate and ſuperacetate of lead, the nitrate of ſilver, and the ſulphates of copper, of zinc, and of iron. They are alſo precipitated by infuſion of galls; the precipitate, as Dr. Duncan juſtly obſerves (Edinb. New Diſpenſ. 6th ed. 382.), reſembling more that produced by cinchonin, than that by gelatine. The ſolution of acetate of barytes, does not alter the ſolutions of Turkey opium, but produces a copious precipitate with thoſe of the Eaſt Indian; oxalic acid precipitates both, but the latter more copiouſly. From theſe experiments, ſays Mr. Thomſon, opium appears to contain reſin, gum, bitter extractive, a peculiar cryſtallizable ſalt, and ſulphate of lime, which appears to be very abundant in the Eaſt Indian opium: the Turkiſh contains alſo a ſpecies of gluten.

It has been diſputed, whether the activity of opium reſides in its gummy or reſinous parts. From the experiments of Hoffmann and Neumann, it ſeems to be neither in the gum, nor in the reſin; but in a certain ſubtile part of the reſinous matter, ſomewhat analogous to eſſential oils, but of a much leſs volatile kind: and they relate, that on boiling the opium in water, there ariſes to the ſurface a frothy, viſcid, unctuous, ſtrong-ſcented ſubſtance, to the quantity of two or three drams from ſixteen ounces; that this ſubſtance, in the doſe of a few grains, has killed dogs that could bear above a dram of crude opium; that in diſtillation with water, though it does not riſe itſelf, it gives over, at leaſt in part, the active principle of which it is the matrix; impregnating the diſtilled liquor with its ſcent and its ſoporific power; as eſſential oils exhale their odoriferous principle in the air, without being diſſipated themſelves. But what this ſubtile and active principle really is, in eſſential oils, odorous vegetables, or opium, is equally unknown. Neumann ſays, that he knows a preparation of opium, by which a whole chamber full of men may be preſently ſtupefied, deprived of their ſenſes, and even of their lives, without ſwallowing a ſingle grain: and he thinks, that it operates much in the ſame manner as the vapours of burning charcoal, or as the exhalations of fermenting liquors.

When ether is uſed as a menſtruum for opium, and the reſin and extractive which it takes up are ſeparated by evaporating the tincture on the ſurface of water, the pellicle of reſin depoſited is nearly inſipid, while the extractive diſſolved in the water has an intenſely bitter taſte: from this fact, and the circumſtance already mentioned, of opium becoming inert when boiled in water, we might venture, ſays Mr. Thomſon, to conclude, that the narcotic principle reſides in the extractive; but Deroſné has lately aſſerted, that the activity of opium depends on a peculiar ſalt. He evaporated a watery infuſion of opium to the conſiſtence of ſyrup, and digeſted the gritty precipitate formed by this evaporation in hot alcohol; as the ſolution cooled, a ſalt was formed, which by repeated ſolutions and cryſtallizations was obtained free from the reſin, of a white colour, and in rectangular priſms with rhomboidal baſes; theſe were inodorous, inſipid, inſoluble in cold water, but ſoluble in 400 parts of boiling water; ſoluble in 100 parts of cold, and 24 of boiling alcohol; ſoluble in hot ether and the volatile oils, but ſeparating as thoſe fluids cooled; and very ſoluble in all the acids. Given to dogs, it produced the effects of a ſtrong doſe of opium; and in a ſimilar manner the bad effects were relieved by vinegar. Mr. Thomſon, in repeating the experiments of Deroſné, obtained a much greater proportion of cryſtals of this peculiar ſalt from Eaſt Indian opium than from that of Turkey, which, in his opinion, militates againſt Deroſné's idea of its being the narcotic principle, as much larger doſes of that variety of opium are required to produce its narcotic effect on the ſyſtem. Mr. Thomſon has had an opportunity of aſcertaining the power of the ſalt; but from Deroſné's account, it is not much more powerful as a narcotic than opium itſelf. This latter writer concludes, from the effects of nitric acid and caloric on this ſalt, that it is compoſed of oxygen, hydrogen, azote, and carbon. It does not redden vegetable blues. Annales de Chimie, lxv. 270. 279.

The uſe of this celebrated medicine, though not known to Hippocrates, can be clearly traced back to Diagoras, who was nearly his contemporary; but its extenſive practical utility has not been long well underſtood, and it may perhaps be dated in this country from the time of Sydenham. Opium is the chief narcotic now employed; it acts directly upon the nervous power, diminiſhing the ſenſibility, irritability, and mobility of the ſyſtem; and according to Dr. Cullen, in a certain manner ſuſpending the motion of the nervous fluid, to and from the brain, and thereby inducing ſleep, one of its principal effects. From this ſedative power of opium, by which it allays pain, inordinate action, and reſtleſſneſs, it naturally follows, that it may be employed with advantage in a great variety of diſeaſes. Indeed, there is ſcarcely any diſorder in which, under ſome circumſtances, its uſe is not found proper; and though in many caſes it fails of producing ſleep, yet if taken in a full doſe, it occaſions a pleaſant tranquillity of mind, and a drowſineſs which approaches to ſleep, and which always refreſhes the patient. Beſides the ſedative power of opium, it is known to act more or leſs as a ſtimulant, exciting the motion of the blood: but this increaſed action has been ingeniouſly, and, as Dr. Woodville thinks, rationally aſcribed to that general law of the animal economy, by which any noxious influence is reſiſted by a conſequent re-action of the ſyſtem. By a certain conjoined effort of this ſedative and ſtimulant power, opium has been thought to produce intoxication, a quality for which it is much uſed in Eaſtern countries.

Dr. Lewis has given us the following view of the general effects of opium. It renders the ſolids, while the operation of the opium continues, leſs ſenſible of every kind of irritation, whether proceeding from an internal cauſe, or from acrimonious medicines, as cantharides, and the more active mercurials, of which it is the beſt corrector. It relaxes the nerves; abating or removing cramps or ſpaſms, even thoſe of the moſt violent kind; and increaſing paralytic diſorders and debilities of the nervous ſyſtem. It incraſſates thin ſerous humours in the fauces and adjacent parts; by which means, it proves frequently a ſpeedy cure for ſimple catarrhs and tickling coughs; but in phthiſical and peripneumonic caſes, dangerouſly obſtructs expectoration, unleſs this effect be provided againſt by ſuitable additions, as ammoniacum and ſquills. It produces a fullneſs and diſtenſion of the whole habit; and thus exaſperates inflammations both internal and external, and all plethoric ſymptoms. It promotes perſpiration and ſweat; but reſtrains all other evacuations, unleſs when they proceed from relaxation and inſenſibility of the parts, as the colliquative diarrhœa in the advanced ſtate of hectic fevers. It promotes labour-pains, and delivery more effectually than the medicines of the ſtimulating kind uſually recommended for that purpoſe; partly perhaps by increaſing plenitude, and partly by relaxing the ſolids, or taking off ſpaſmodic ſtrictures. And indeed all the preceding effects are perhaps conſequences of one general power, being nearly allied to thoſe, which natural ſleep produces.

The operation of opium is generally accompanied with a ſlow but ſtrong and full pulſe, and a ſlight redneſs, heat, and itching of the ſkin: it is followed by a weak and lan-

guid

guid pulſe, lowneſs of the ſpirits, ſome difficulty of breathing, or a ſenſe of tightneſs about the breaſt, a ſlight giddineſs of the head, dryneſs of the mouth and fauces, and ſome degree of nauſea. Given on a full ſtomach, it commonly occaſions a nauſea from the beginning, which continues till the opium is rejected along with the contents of the ſtomach. Where the evacuation of acrid humours, accumulated in the firſt paſſages, is ſuppreſſed by it, great ſickneſs and uneaſineſs are generally complained of, till the ſalutary diſcharge either takes place again ſpontaneouſly, or is promoted by art.

An over-doſe occaſions either immoderate mirth or ſtupidity, a redneſs of the face, ſwelling of the lips, relaxation of the joints, vertigo, deep ſleep, with turbulent dreams and ſtartings, convulſions, and cold ſweats. Geoffroy obſerves, that thoſe who recover are generally relieved by a diarrhœa, or by a profuſe ſweat, which is accompanied with a violent itching. The proper remedies, beſides emetics, bliſters, and bleeding, are acids and neutral mixtures. Dr. Mead ſays, he has given, with extraordinary ſucceſs, repeated doſes of a mixture of ſalt of wormwood and lemon juice. The firſt thing to be done for counteracting the injurious effects of too large a doſe, is the exhibition of a powerful emetic: and for this purpoſe, ℈ i of ſulphate of zinc, or from grs. v to grs. x of ſulphate of copper, diſſolved in water, ſhould be immediately ſwallowed; and the vomiting kept up for a conſiderable time, and urged by irritation of the fauces. Large draughts of vinegar and water, or other acidulated fluids, ſhould be taken; and the powers of the habit ſupported by brandy, coffee, and cordials. The ſufferer ſhould be kept awake, and, if poſſible, in continued gentle motion. Currie recommends for removing the drowſineſs, the affuſion of warm water at 106° or 108°.

A long continued uſe of opium is productive of great relaxation and debility, ſluggiſhneſs, heavineſs, loſs of appetite, dropſies, tremors, acrimony of the humours, frequent ſtimulus to urine, and propenſity to venery. On leaving it off, after habitual uſe, an extreme lowneſs of the ſpirits, languor, and anxiety ſucceed; which are relieved by having again recourſe to opium, and, in ſome meaſure, by ſpirituous or vinous liquors. Lewis's Mat. Med.

The virtues of opium, internally taken, depend chiefly on its action on the ſtomach. There are many inſtances of terrible ſymptoms, and death itſelf, cauſed by narcotics, before they went out of the ſtomach, and without inflaming it, or cauſing any viſible change in it, far leſs vitiating the maſs of blood; and alſo the ſame ſymptoms being removed, and death prevented by vomiting. Dr. Alſton is alſo of opinion, 1. That the anodyne and hypnotic virtues of opium do not depend on its action on the brain or on the blood. 2. That it affects firſt and principally the nerves to which it is applied; next ſuch as more immediately communicate with them; then thoſe which ſerve for ſenſation and voluntary motion; and, laſt of all, by conſent, the whole nervous ſyſtem. 3. That this impreſſion on the nerves differently affects the ſenſorium commune and the mind, according to its degree, and the nature and function of the nerves primarily acted upon. 4. That the primary, or firſt obſervable effect of the mechanical impreſſion of the narcotic part of opium on the nerves, is the relaxation of the fibres. Now as this relaxation of the nerves, and conſequently of the moving fibres, demonſtrates opium to be more than a palliative remedy in a great many diſeaſes; ſo it is not difficult by it to account for its bad as well as good effects. For by relaxing to a certain degree, it may prove anodyne, cordial, diaphoretic, hypnotic, &c. or cauſe ſtagnations, deliriums, lethargies, apoplexies, and death.

The particular diſorders in which the uſe of opium has been recommended are the following. In moſt continued fevers of this climate, though originating from contagion, or certain corruptions of human effluvia, &c. there is, at the beginning, more or leſs of an inflammatory diatheſis; and while this continues, opium would generally aggravate the ſymptoms, and prove dangerous. Its uſe is likewiſe forbidden in the more advanced ſtage of this fever, whenever topical inflammation of the brain is aſcertained, which ſometimes exiſts and produces delirium, though other ſymptoms of the nervous and putrid kind prevail. But when irritation upon the brain is not of the inflammatory kind, and debility has made much progreſs, or where delirium is accompanied with ſpaſmodic affections, opium is a ſovereign remedy, and may be employed in large doſes every eight hours, unleſs a remiſſion of the ſymptoms and ſleep take place. In typhus, when given in ſmall doſes frequently repeated, opium is an uſeful aſſiſtant to wine and tonics, in ſupporting the vis vitæ; and at the ſame time allays irritation, and obtunds the ſuſceptibility of thoſe morbid impreſſions which occaſion watchfulneſs, delirium, tremors, and ſubſultus tendinum. It ſhould be adminiſtered, however, with caution; for if the heat of the body be much above the natural ſtandard, and the ſkin dry, opium increaſes theſe ſymptoms, augments thirſt, and occaſions reſtleſſneſs. But if moiſture be coming on, opium accelerates it, and tranquillity and ſleep follow. Hence Dr. Currie's advice ſhould be regarded, not to give the evening doſe of opium in theſe fevers till very late, or about one or two o'clock in the morning, when the heat is ſubſiding; or firſt to lower the temperature, and excite ſenſible perſpiration by the affuſion of cold water, or tepid ſponging. Opium is hurtful alſo when there is a diſpoſition to inflammation, particularly in the cheſt, and when there is much determination to the head.

In intermittent fevers, opium, in combination with other medicines, was much uſed by the ancients; but ſince the introduction of the Peruvian bark, it is ſeldom confided in for the cure of theſe diſorders. It has, however, been ſtrongly recommended as an effectual means of ſtopping the recurrence of the febrile ſymptoms; and has been given, before the fit in the cold ſtage, in the hot ſtage, and during the interval, with the beſt effects; producing immediate relief, and in a ſhort time curing the patient, without leaving thoſe abdominal obſtructions which have been aſcribed to the bark. Berryat, who, in the "Mem. preſentés à l'Acad. Royal. des Sci. 1755, t. ii." ſtrongly recommends the uſe of opium in intermittents, and adviſes it to be given along with an infuſion of centaury, an hour before the acceſs of the paroxyſm. Lind (Diſ. in hot Climates) prefers giving it half an hour after the commencement of the hot fit. In theſe fevers, perhaps, ſays Dr. Woodville, the beſt practice is to unite opium with the bark, which enables the ſtomach to bear the latter in large doſes, and adds conſiderably to its efficacy.

In inflammatory diſeaſes, the uſe of opium has been much condemned; and Young has eſtabliſhed a general rule, "that opium is improper in all thoſe diſeaſes in which bleeding is neceſſary." This principle, however, has been much diſputed; and it is liable to numerous exceptions, ſpecified by Dr. Cullen in his "Materia Medica."

When opium is ſo managed as to procure ſweat, it will tend to remove an inflammatory ſtate of the ſyſtem, and may prove generally uſeful, of which we have a notable inſtance in the cure of acute rheumatiſm by means of Dover's powder. In this latter diſeaſe it is given united with ipecacuanha, or antimonials and nitre, and always gives relief, when it determines to the ſurface.

For the ſmall-pox, opium, ſince the time of Sydenham, has been very generally and ſucceſsfully preſcribed, eſpecially after the fifth day of the diſeaſe; but during the firſt ſtage of the eruptive fever, it has been ſaid that it always does harm; an opinion which Dr. Woodville's experience at the Small-pox Hoſpital contradicts: for he ſays, that even at that period of the diſorder, we often find the pulſe languid, and the countenance pale, though pains in the loins and the head are at the ſame time very ſevere. Theſe ſymptoms, with reſtleſſneſs, and other ſigns of irritability, which appear for ſome days after the attack of the diſeaſe, are conſiderably relieved by opium; to which, however, we uſually add camphor and vinum antimonii tartariſati, always taking care to keep the body ſufficiently open by the frequent doſe of a proper cathartic. In malignant ſcarlatina, pemphigus, and ſeveral others of the exanthemata, it is equally valuable; but in this claſs of diſeaſes its uſe is contra-indicated, when the fever is inflammatory.

In hæmorrhagic diſorders the uſe of opium is inferred, from its known effects in reſtraining all the excretions, except that of ſweat; but unleſs the hæmorrhages be of the paſſive kind, or excited by irritation, unattended with inflammation, opium may produce conſiderable miſchief, and therefore its uſe in theſe complaints requires great circumſpection. Hence ariſes its efficacy in the floodings of irritable habits after abortions, and in phthiſical hæmoptyſis. It has been alſo recommended after blood-letting, in the hæmoptyſis and hæmatemeſis of the later months of pregnancy. In dyſentery, opium may be occaſionally employed to moderate the violence of the ſymptoms. In diarrhœa, eſpecially when the acrimony has been carried off by a continuance of the diſeaſe, opium is a certain and efficacious remedy. In cholera and pyroſis, opium is the remedy chiefly confided in. In chorea Sti. Viti it has been found beneficial, when preceded by ſtrong cathartics, or combined with theſe. In epilepſy it is uſeful, when given in combination with muſk. In ſpaſmodic aſthma it ſhortens the paroxyſms, abates the violence of the cough in pertuſſis, when adminiſtered after the primary fever ſubſides. Although opiates are hurtful at firſt, and check expectoration in catarrh, yet when the cough is obſtinate, their good effects are unqueſtionable; and in the contagious catarrh, or influenza, an opiate at bed-time is requiſite for quieting the cough in every ſtage of the diſorder. In colic it is employed with laxatives, and often prevents ileus and inflammation, by relieving the ſpaſm. Even in ileus and incarcerated hernia, it is often found to allay the vomiting, the ſpaſms, the pain, and ſometimes to diminiſh the inflammation, and prevent the gangrene of the ſtrangulated gut. Opium has been lately recommended for the cure of the lues venerea, and ſome have ſaid that it has ſucceeded when mercury has failed: but however it has been extolled by ſome foreigners, its antivenereal powers have been exploded in this country; though, as an auxiliary to mercury, it has been conſidered as uſeful, by diminiſhing the ſenſibility of the ſtomach and bowels, and thus preventing many of thoſe inconveniences which this mineral is apt to excite in the primæ viæ, and allowing it to be more eaſily introduced into the ſyſtem. Its uſe in preventing and ſtopping the progreſs of gangrene is well eſtabliſhed. Opium is ſucceſsfully uſed in various ſpecies of tetanus, and affords relief to various ſpaſmodic and convulſive ſymptoms occurring in ſeveral diſeaſes. Indeed, in all caſes where the irritability is morbidly increaſed, and where it is of importance to leſſen pain, and procure ſleep, opium is undoubtedly the moſt valuable article of the materia medica. But its uſe is contra-indicated in all morbid ſtates of the body, when a ſtrong inflammatory diatheſis exiſts; in pulmonary affections, when the cough is dry and hard, and the expectoration difficult and ſcanty; and if not hurtful, its utility is doubtful in mania, in which it generally occaſions reſtleſſneſs, inſtead of procuring ſleep.

Although ſome difference of opinion ſubſiſts with regard to the external application of opium, it has been maintained that, externally applied, it is almoſt as efficacious as when it is taken into the ſtomach, and that it produces its narcotic effects without affecting the head, or occaſioning nauſea. Accordingly it has been ſaid, that when applied to the ſkin, it allays pain and ſpaſm, procures ſleep, and produces other ſalutary effects. The uſual mode of applying it is in form of frictions, either combined with oil, or with the camphor liniment, or in the form of tincture; and in this mode it may be uſed in all the diſeaſes above enumerated. Its good effects in colic, alſo in ſymptomatic triſmus, when rubbed on the jaw, and when applied to the ſcrobiculus cordis by means of pledgets ſoaked in the tincture, have been obſerved by medical practitioners. A piece of ſolid opium, ſtuffed into a carious tooth, relieves the pain of tooth-ache; and introduced into the rectum, either in a ſolid form, or diſſolved in water as an enema, affords relief in teneſmus, in painful affections of the proſtate gland, and in ſpaſmodic ſtrictures. A weak watery ſolution of it is an uſeful adjunct to injections in gonorrhœa, and to collyria in ophthalmia; and the vinous tincture dropped into the eye removes the ſuffuſion which often remains in that diſeaſe, after the inflammation has been ſubdued, and reſtores the tone of the diſeaſed organ. One inconvenience following the moderate application of opium, mandragora, and hyoſcyamus for pains of the eyes, taken notice of by Galen, is the midriaſis, or a preternatural dilatation of the pupils. Mr. Ray gives a notable inſtance of this kind, ariſing from the application of a leaf of the deadly nightſhade to a cancerous ulcer a little below the eye. The uvea, in a night's time, entirely loſt its muſcular force, and was ſo relaxed, that the pupil, in the cleareſt light, remained four times bigger than that of the other eye. The effects of opium on other animals are not much different from its effects on men. Applied to the naked nerves of animals, it produces immediate torpor, and loſs of power in all the muſcles with which the nerves communicate. Dr. Alſton put a few drops of a ſolution of opium into a frog's ſtomach, and the circulation of the blood of the animal being examined by a microſcope, no alteration was perceived in the blood, as to its conſiſtence, colour of the ſerum, magnitude, figure, or colour of the red globules; but its velocity was ſurpriſingly diminiſhed. In about half an hour, the blood regained its common celerity, and the frog its vigour. On giving the creature a ſecond doſe, the blood moved ſlower than it did the firſt time, and its velocity gradually decreaſing, ſtagnated firſt in the ſmaller, then in the larger veſſels; and in a quarter of an hour the frog expired. It is remarkable, that notwithſtanding the diminution of the velocity of the blood, the pulſe was not leſs frequent; and that even when the circulation ſtopt in the foot, the pulſe remained viſible by an undulatory motion. On opening the frog, its ſtomach was found full of a clear mucus, tinged with the opium, and every thing alſo ſeemed perfectly natural. This experiment was repeated ſeveral times, with the ſame appearances.

A dog being killed by an injection of a ſolution of opium into his crural vein, on opening his thorax the lungs were found ſound, but very ſmall, and white, without any blood in them. The heart was big, and all its great veſſels diſtended with blood; but nothing preternatural was obſerved in the brain or abdomen.

Opium is exhibited either in ſubſtance as a pill or under

the form of tincture. It is neceſſary, however, to take heed that it be not combined with ſubſtances which decompoſe it; and therefore ſolutions of oxymuriate of mercury, acetate of lead, ſulphates of zinc, iron, and copper; of the carbonates of alkalies, lime-water, infuſion of galls, and infuſion of yellow cinchona bark, are incompatible in preſcriptions with opium.

The requiſite doſe of opium varies in different perſons, and in different ſtates of the ſame perſon. A quarter of a grain will in one adult produce effects which ten times the quantity will not do in another, more eſpecially if he has been previouſly accuſtomed to the uſe of it; and a doſe that might prove fatal in cholera or colic, would not be perceptible in many caſes of tetanus or mania. A quarter of a grain, frequently repeated, is in general ſufficient to keep up its ſtimulant effect; and the quantity of from gr. j to gr. ij acts as a narcotic, and produces ſleep; while in tetanus, hydrophobia, and ſome other diſeaſes, ʒvſs of laudanum have been given in twenty-ſix hours, without occaſioning any bad effects, or even producing ſleep. The loweſt fatal doſe to thoſe unaccuſtomed to take it ſeems to be about four grains; but a dangerous doſe is ſo apt to produce vomiting that it has ſeldom time to occaſion death. When given in too ſmall a doſe, it often produces diſturbed ſleep, and other diſagreeable conſequences; and in ſome caſes it ſeems impoſſible to be made to agree in any doſe or form. Often, on the other hand, from a ſmall doſe, ſound ſleep and alleviation of pain will be produced, while a larger one occaſions vertigo and delirium. Some prefer the repetition of ſmall doſes; others give a full doſe at once; its operation is ſuppoſed to laſt about two hours. It is uſe that makes the quantity of opium ſafe, and even beneficial, which would otherwiſe prove poiſonous. Daily experience confirms this; and they who habituate themſelves to opium, find it as neceſſary as ſpirituous liquors to tiplers, and can take fifty or ſixty grains: Charas ſays, that he has taken twelve grains himſelf, and adds, that he knows one who made no ſcruple of thirty-ſix. And in the Phil. Tranſ. we have an inſtance of one Mr. Lovelock, who, in a fever, in three days time, took one hundred and two grains.

A few grains will deſtroy a perſon unaccuſtomed to it; but ſome diſorders, as madneſs, enervate its force. Among the Eaſtern nations, a dram of opium is but a moderate doſe. The Turks are ſaid to take this quantity when they go to battle, or undertake any affair that requires vigour and ſtrength. Garcias mentions one who took ten drams every day, and though ſhe appeared ſtupid and ſleepy, yet ſhe diſputed very readily and learnedly on any ſubject. It is remarkable that, notwithſtanding this exceſſive uſe of opium, the Turks are generally long lived, if we credit Bellonius.

The action of opium is very analogous to that of wine or vinous ſpirits; the good and ill effects of both differ little. See Wedelius in his Opiologia, and Geoffroy's Materia Medica. Platerus affirms that wine is narcotic, and Sydenham, that opium is the moſt excellent cordial in nature.

Dr. Smyth, while at Smyrna, took pains to obſerve what the doſes of opium taken by the Turks, in general, were. He found that three drams in a day were a common quantity among the larger takers of it, but that they could take ſix drams a day without miſchief. A Turk eat this quantity before him, three drams in the morning, and three in the evening, with no other effect than its giving him great chearfulneſs. But the taking it thus habitually greatly impairs the conſtitution; the perſons who accuſtom themſelves to it, can by no means live without it, and are feeble and weak; their legs are uſually thin, and their gums eaten away, ſo that the teeth ſtand bare to the roots; they are alſo often of a yellow complexion, and look much older than they really are. The Turkiſh meſſengers, when ſent upon buſineſs of haſte, always carry opium with them, and take largely of it when tired; they ſay it immediately gives them ſtrength and ſpirits to proceed, taken with proper precaution. Phil. Tranſ. N° 223.

Dr. Ruſſell, in his "Hiſtory of Aleppo," informs us, that the greateſt quantity he knew to be taken, was three drams in twenty-four hours; and the immediate effects which he obſerved it to have on ſuch as were addicted to it, were, that their ſpirits were exhilarated, and from a doſing, depreſſed ſtate into which they ſunk, after paſſing the uſual time of taking their doſe, they became quite alert. The conſequences of a long uſe of it are, that they ſoon look old and beſotted, like ſuch as in Europe have ruined their conſtitutions by hard drinking. The habitual uſe of it cannot be too much reprobated. It impairs the digeſtive organs, conſequently the vigour of the whole body, and deſtroys alſo gradually the mental energies. The effects of opium on thoſe who have been addicted to it, ſays Ruſſell, are at firſt obſtinate coſtiveneſs, ſucceeded by diarrhœa and flatulence, with loſs of appetite and a ſottiſh appearance. And it may be conſidered as a point of fact, that they ſeldom live to a good old age: though they are rarely carried off by dropſies or ſuch other diſeaſes, which are the uſual conſequences of hard drinking amongſt us; but having firſt loſt their memory, and moſt of their intellectual faculties, they decline, in all appearance, in the ſame way as thoſe who ſink under the weight of years.

We have an account, in the Memoirs of the Academy of Sciences at Paris, of the death of a young man at Cairo, from his being decoyed into taking a very large doſe of this medicine. Among a number of young people in that city, who frequently drank together, there was one who always boaſted of his ſuperior power to bear a large quantity of liquor; and his companions, determined to get the better of him for once, diſſolved, without his knowing of it, a dram of opium in the liquor he was to drink; the conſequence was, that, inſtead of falling aſleep, as they expected he would, he fell into violent deliriums, and afterwards into a profound and dead ſleep.

The next morning his comrades went to ſee him, and triumphed in their victory, but found him dying, looking livid, without pulſe, and with his mouth cloſed. They ſent for aſſiſtance, but in vain. After the death of the perſon, the body, arms, and thighs, became covered with livid tumours, as big as the head of a young child, and theſe emitted an intolerable ſtench, almoſt as ſoon as the corpſe was cold. There is one very ſingular accident in regard to this caſe, which is, that this ſtench allured all the cats from the neighbouring houſes, who came with great eagerneſs, and were hardly prevented from devouring the body.

The officinal preparations of opium are opium purificatum, confectio opii, electuarium catechu, extractum opii, pilulæ opii, pilulæ ſaponis cum opio, pulvis opiatus, pulvis cornu uſti cum opio, pulvis cretæ comp. cum opio, pulvis ipecacuhanæ comp., tinctura opii, tinctura camphoræ compoſita, tinctura opii ammoniata, and trochiſci glycyrrhizæ cum opio.

The *opium purificatum*, or purified opium, of the Dublin diſpenſatory, is prepared by cutting one pound of opium into ſmall pieces, and digeſting it in 12 pints of proof ſpirit with a gentle heat and frequent agitation, until the opium is diſſolved; then filtering the ſolution through paper; and diſtilling it from a retort to ſeparate the ſpirits; pouring in the reſiduary liquor, and evaporating it until the extract be of a proper thickneſs. Purified

opium

opium muſt be kept in two ſtates; one ſoft, proper for forming pills, and one hard, capable of being reduced to powder.

The *confectio opii* of the London pharmacopeia is prepared by taking 6 drams of hard opium powdered, 1 oz. of long pepper, 2 oz. of ginger root, and 3 oz. of caraway ſeeds; and rubbing the opium in a pint of ſyrup made hot; then adding the remaining articles pulverized, and mixing the ingredients.

The *electuarium opiatum*, or opiate electuary, formerly *electuarium thebaicum* or thebaic electuary of the Edinb. pharm., is compoſed of 6 oz. of aromatic powder, 3 oz. of Virginian ſnake-root in fine powder, half an ounce of opium, diffuſed in a ſufficient quantity of Spaniſh white wine, and a pound of ſyrup of ginger; which ingredients are mixed ſo as to make an electuary.

The operation of the opium in theſe preparations is modified by the aromatics. They are intended as ſubſtitutes for the mithridate and theriaca of the old pharmacopeias. They are ſtimulant narcotics; and are uſefully employed in atonic gout, flatulent colic, and in diarrhœas, unattended with inflammatory ſymptoms. Thirty-ſix grains of the London confection contain 1 grain of opium, and the ſame quantity is contained in 43 of the Edinb. electuary. The doſe is from grs. x to ʒj, given in the form of bolus, or diffuſed in the chalk mixture.

The *electuarium mimoſæ catechu*, olim *confectio Japonica*, electuary of catechu, formerly Japonic confection of Edinb. pharm., is compoſed of 4 oz. of extract of catechu, 3 oz. of kino, of cinnamon bark and nutmegs, of each 1 oz., 2¼ lbs. of opium, diffuſed in a ſufficient quantity of Spaniſh white wine, and 2¼ lbs. of ſyrup of red roſes boiled to the thickneſs of honey. Reduce the ſolid ingredients to powder, and then mix them with the opium and ſyrup ſo as to form an electuary. The *electuarium catechu compoſitum*, or compound electuary of catechu of the Dub. pharm., conſiſts of 4 oz. of catechu, 2 oz. of cinnamon bark, 3 oz of kino; rub theſe to powder, and add of hard refined opium diffuſed 1½ dram in Spaniſh white wine, and 2¼ lbs. of ſyrup of ginger boiled to the conſiſtence of honey; and mix them.

Theſe are uſeful combinations as aſtringents and aromatics; and may be efficaciouſly given in diarrhœas, and the laſt ſtage of dyſentery, either in the form of bolus, or diffuſed in ſome diſtilled water. The doſe is from ℈j to ʒij. Ten ſcruples contain one grain of opium.

The *extractum opii*, extract of opium of the Lond. pharm., is formed by taking ½ lb. of opium ſliced, and 3 pints of water; pouring a ſmall portion of the water upon the opium, and macerating for twelve hours, that it may become ſoft; then adding gradually the remaining water, rubbing them together until they be well mixed, and ſetting the mixture apart that the feculencies may ſubſide; laſtly, ſtraining the liquor, and evaporating it to a proper conſiſtence.

The *extractum opii aquoſum*, or watery extract of opium of the Dub. Ph., is formed by rubbing two ounces of opium in a pint of boiling water for ten minutes, and, after a little time, pouring off the ſolution; then rubbing the reſidue of opium in an equal quantity of boiling water for the ſame time, pouring off this ſolution, and repeating the ſame operation a third time; then mixing together the decanted ſolutions, and expoſing the mixture in a broad open veſſel to the air for two days; and, laſtly, ſtraining it through linen, and by ſlow evaporation forming it into an extract.

From lbſs of crude opium ʒijſs only of extract are obtained by following the directions of the London college. This extract, which is inodorous, of a bitter taſte, and of a very deep brown colour, not altogether ſoluble in water, and not precipitated from its ſolution by alcohol, nevertheleſs affords precipitates with the following ſolutions, which ſhould not therefore enter into preſcriptions with its ſolution, *viz.* ſolutions of aſtringent vegetables, the alkaline carbonates, corroſive muriate of mercury, ſulphate of copper, ſulphate of zinc, acetate of lead, and nitrate of ſilver. This extract is ſuppoſed to poſſeſs the narcotic and anodyne powers of opium, but to produce its effects with leſs ſubſequent derangement of the nervous ſyſtem. It is therefore ſuppoſed to be well adapted for the diſeaſes of children, and of perſons of very irritable habits. The doſe is from gr. j to grs. vi for an adult. The officinal preparation is *ſyrupus opii*. See Syrup.

For an account of *pills*, *powders*, and *tinctures* of opium, ſee the reſpective articles; and for the officinal preparations of poppy capſules, ſee Papaver. Woodville's Med. Bot. Thomſon's London Diſpenſatory.

Opium *Cyreniacum*, in the *Materia Medica*, a name given by ſome of the writers of the middle ages to aſſa fœtida. This was the *ſcordolaſaron* of the Greek writers of thoſe times, and was called *Cyreniacum* from the place whence it was principally brought. Avicenna tells us, that, in his time, it was brought principally from Kirvan, and that is Cyrene.

OPIUS, Oph, in *Ancient Geography*, a town of Aſia, near the Euxine ſea, between the mouths of two rivers, and E.S.E. of Trapezus.

OPIZUM, a town of Thrace, between Hadrianopolis and Philippopolis.

OPLITODROMI, Οπλιτοδρομοι, among the Greeks, a deſignation given to thoſe who ran in armour, at the Olympic, and other games.

The word comes from the Greek οπλον, *armour*, and δρομος, *a race*.

OPOBALSAMUM, in *Pharmacy*, a whitiſh juice, gum, or reſin, diſtilled from the branches of a tree, called *balſamum*, or the balſam-tree. See Amyris.

To obtain the balſam, the bark is cut by an ax, when the juice is in its ſtrongeſt circulation, in July, Auguſt, and the beginning of September. It is then received into a ſmall earthen bottle, and every day's produce collected and poured into a larger, which is kept cloſely corked. The firſt that flows, called "opobalſamum," is of a light yellow colour, apparently turbid. It afterwards becomes clear, fixed, and heavier; and the colour by degrees to a golden yellow. The "opobalſamum" of the ancients was compoſed of the green liquor found in the kernel of the fruit; the "carpobalſamum," the next in eſteem, was made by the expreſſion of the ripe fruit; and "xylobalſamum," or worſt kind, by the expreſſion or decoction of the ſmall twigs. In the earlier ages, this balſam was eſteemed as a medicine of almoſt univerſal virtue; and at the preſent day the Arabs uſe it in all complaints of the ſtomach and bowels, reckoning it a powerful antiſeptic, and preventive of the plague; but its chief uſe among the Turkiſh ladies is as a coſmetic. It is never brought genuine into this country. See Balsam *of Gilead*.

OPOCALPASON, Opocarpason, οποκαλπασον, οποκαρπασον, the juice of a tree called *calpaſi*; this juice reſembles myrrh, but is poiſonous and deadly, inducing a ſtrangulation. Galen, de Antidot. lib. i. ſays, that in the courſe of his time, he had obſerved the fatal effects in many who had ignorantly taken myrrh mixed with opocalpaſum. For they who prepare antidotes, he ſays, purpoſely mix this as an ingredient, taking it for the beſt ſort of myrrh; becauſe they had obſerved it to be a very good medicine in collyria,

collyria, where it attenuates ſanies without corroſiveneſs, and ſometimes removes an incipient cataract. And if you put, ſays he, this kind of myrrh into a plaſter, cerate, or any attenuating medicine, to be outwardly applied, you will increaſe its virtue, but the effects of it taken into the body are deadly. James.

OPODELDOC, in the *Materia Medica*, the name of a plaſter ſaid to be invented by Mindererus, though often mentioned by Paracelſus. There uſed to be a famous popular ointment under the name of opodeldoc, which, it is ſaid, was thus prepared.

Take of the root of marſhmallows, comfrey, gentian, long birthwort, angelica, of each one ounce and a half; of the herbs ſanicle, ladies' mantle, mouſe-ear, colt's-foot, ſnakeroot, periwinkle, bruiſed, of each half a handful; of the leaves of roſemary, ſage, and lavender, of each one handful; juniper berries, two ounces; cumin ſeeds, one ounce; camphor and caſtor powdered, of each one ounce and a half; and of ſpirit of wine, three pints and a half.

Put all into a glaſs cucurbit, well luted, and digeſt for ten hours in balneo Mariæ, that is in hot water, but not to boil, then ſtrain; and the ſpirit of wine being ſufficiently impregnated with the ingredients, then add one pound of Caſtile ſoap ſhaved thin; digeſt in the ſame manner as before, until the ſoap is diſſolved.

Lute the juncture carefully, with two or three doubles of paper, daubed over with the white of eggs, and tied about with thread; the luting being dried, then digeſt in balneo Mariæ for ten hours, the matraſs being fixed in the middle of the kettle, with a layer of ſtraw under it, to keep it at the diſtance of two inches from the bottom: for the firſt eight hours, keep the water ſo hot about it, that you can ſcarce hold your finger therein; and the two other hours augment the heat, but not ſo much as to make the water boil.

After the ſpirit of wine is thoroughly impregnated with the tincture of the roots, herbs, leaves, and powders, cool it gently, and ſtraining it through a linen cloth, pour it again into the matraſs, with one pound of Caſtile ſoap, ſhaved thin; then fit the veſſel of rencounter to the matraſs; lute the junctures, and digeſt as before, till the ſoap is entirely mixed with the ſpirit, and the whole reduced to an ointment; then take out the matraſs, and ſuffer it to cool.

If the doſes and other directions are duly obſerved, it will be of the conſiſtence of an unguent, neither too thick nor thin, and the method of trying if it is truly prepared, is, to rub ſome of it on your hand, which it will immediately penetrate, leaving only a greeniſh ſtain; though the natural colour of the ointment is brown. It is excellent in ſtrains, relaxations of the ſinews in horſes, as well as in the human kind; alſo in all pains, numbneſs, weakneſs in the joints, or other parts, being well rubbed in. James.

The Edinburgh Pharmacopeia directed the opodeldoc to be made in a much more ſimple manner, *viz.* by digeſting two ounces and a half of Spaniſh ſoap, in a pint of rectified ſpirit of wine, and afterwards adding half an ounce of camphor, a dram of oil of roſemary, and a dram of oil of origanum. See SOAP.

OPODEOCELE, in *Surgery*, a hernia at the foramen ovale of the pelvis. See HERNIA.

OPODIPE, in *Geography*, a town of New Navarre; 170 miles S. of Caſa Grande.

OPOGKA, a town of Ruſſia, in the government of Pſkov, on the Velika. N. lat. 56° 40′. E. long. 29° 14′.

OPOLLA, a town of Poland, in the palatinate of Sandomirz; 30 miles W.S.W. of Sandomirz.

OPOORAGE, a ſmall iſland near the E. coaſt of New Zealand, a little to the S. of Mercury bay. S. lat. 56° 51′. W. long. 183° 54′.

OPOPANAX, Οποπαναξ, formed from οπος, *juice*, and πανακ, the name of the plant which yields it, or *Opoponax*, in *Pharmacy*, a concrete gummy reſinous juice, of a reddiſh-yellow colour, yellow and ſpeckled with white on the outſide, paler within, and frequently variegated with large white pieces; fatty, and brittle, of a bitter, acrid, and ſomewhat nauſeous taſte, and a very ſtrong, diſagreeable ſmell. Its ſpecific gravity is 1.622. It appears to be a compound of gum, reſin, and eſſential oil.

The Latins call it *panax Herculeum*, from Hercules, who is ſuppoſed to have firſt diſcovered its ſpecific virtues. It is one of the three celebrated panaceas, or univerſal medicines, to which the ancients attributed ſuch wonderful virtues. The two others are the Aſclepium and Chironium; the firſt found by Æſculapius, the ſecond by Chiron.

The gum opopanax flows by inciſion from the roots of a plant (the PASTINACA *Opopanax*, which ſee,) and being dried in the ſun, is brought from Turkey, and the Eaſt Indies, in cheſts; and is ſometimes in tears or drops, but more uſually in irregular lumps. The plant grows abundantly in Achaia, Bœotia, Phocis, and Macedonia. There are three kinds of it imported; that in tears; that in the maſs; and that counterfeited, or flatted. The firſt is the beſt, and the ſecond is the better, as it has the more tears; the third is a rank ſophiſtication, and good for little.

When triturated with water, about one-half of it diſſolves, forming an opaque milky ſolution, which, on ſtanding, depoſits a portion of reſinous matter, and becomes yellowiſh. Alcohol acts upon it freely; and in diſtillation either with it or with water, the odour of the opopanax is very ſtrongly communicated to the fluids, but ſcarcely any oil is obtained in a ſeparate ſtate. This gum-reſin is regarded as antiſpaſmodic and emmenagogue, and as ſuch has been uſed in hyſteria and chloroſis; but it is now very ſeldom ordered. The doſe may be from grs. x to ʒſs. Woodville. Thomſon.

OPOPIA, a name given by ſome anatomical writers to the bones which form the receptacle of the eyes.

OPORICE, a name given by the ancients to a medicine compoſed of the autumnal fruits, and extolled for its great virtues againſt weakneſſes of the ſtomach and dyſenteries.

It was compoſed of five quinces with their ſeeds, as many pomegranates, a pint of ſervices, a pint of Syrian ſumach, and half an ounce of ſaffron; all theſe were put together into a gallon of muſt, and boiled over a very gentle fire to the conſiſtence of honey, with great care to avoid burning.

OPORINUS, JOHN, in *Biography*, a learned printer, born at Baſil in 1507, was the ſon of a painter, in indigent circumſtances, named Herbſt. He was inſtructed in the elements of the Latin language by his father, and afterwards paſſed four years at the univerſity of Straſburg, maintaining himſelf by teaching the younger ſtudents, by copying manuſcripts, and correcting the preſs. When, by his ſervices in the cauſe of literature, he felt himſelf of ſufficient conſequence to aſſume a claſſical name, he changed that of Herbſt, ſignifying Autumn or Harveſt, to Oporinus, which has the ſame meaning in the Greek language, and to improve his circumſtances, he married an old lady who was poſſeſſed of a good fortune, the whole of which would have ill compenſated for her crabbed temper; nevertheleſs, at her death the property was transferred to other perſons. He was adviſed to ſtudy phyſic, and engaged himſelf as pupil and ſecretary to the famous Paracelſus. This maſter promiſed to communicate to him ſome medical ſecrets; but failing in the

the performance, Oporinus left him, and ſet up a ſchool for inſtructing young people in the claſſics at Baſil. At length he went into the printing buſineſs, in partnerſhip with a perſon named Robert Winter, who gave himſelf, according to the faſhion of the times, the Greek name of Chimerinus. He was indefatigable in his employment, keeping, by his ſole labour, ſix preſſes at work, and publiſhing no book which he had not corrected himſelf. His induſtry was not requited by good fortune: perhaps he was too much of a ſcholar to be a ſucceſsful man of buſineſs. He died in debt at the age of ſixty-one. Being an accurate judge of manuſcripts, he printed none but the moſt valuable, and he took care that they ſhould appear in the moſt correct form. He was author of many excellent notes upon the books which he printed, and compiled very uſeful tables of contents and indexes of others. His principal writings were "Notes upon Solinus;" "Scholia upon the Tuſculan Queſtions of Cicero;" and alſo upon other works of that author; "Notes upon ſome Parts of Demoſthenes;" "Darii Tiberti Epitome Vitarum Plutarchi ab innumeris mendis repurgata;" "Propriorum Nominum Onomaſticon." Some of his Latin letters are printed in a collection of epiſtles publiſhed at Utrecht in 1697. Moreri.

OPORTO, or PORTO, in *Geography*, the largeſt city, Liſbon excepted, and ſea-port, of Portugal, in the province of Entre Duero é Minho, ſituated on the declivity of a hill, in an elevated ſituation near the river Duero, and about three-fourths of a league from its mouth. It is the chief town of a corregimento, and the ſeat of a corregedor, a provedor, and a military governor, being a place of arms: it is alſo the ſee of a biſhop, who chiefly reſides at Mezanfrio. Murphy ſtates the number of inhabitants at 63,505; but Link, on the authority of the corregedor, eſtimates the population at this time to be about 30,000. Oporto has four ſuburbs, ſeven pariſhes, and twelve religious houſes. On one ſide the remains of the walls and gates ſtill exiſt; otherwiſe the town is quite open, and has no fortifications. It is alſo the ſeat of the high tribunal for the northern provinces. The quay on the river is built without art; on one ſide is a ſtreet, the other ſide is walled and raiſed, though merely for the purpoſe of making ſhips' cables faſt. From the ſtrand riſes a broad well-paved ſtreet, with cauſeways on the ſides, leading to an equally handſome oblique ſtreet. The other ſtreets along the declivity of the hill are narrow, crooked, and dirty; but upon the hill are many fine, broad, ſtraight ſtreets, with a number of new and handſome houſes. All the buildings are regular, light and neat, and this town is allowed to be the cleaneſt in Portugal. The ſteep declivity of the hill on which the town is built renders walking and riding on horſeback or in carriages more laborious than in Liſbon. On the E. ſide of the town, houſes are built againſt ſo ſteep a part of the declivity over the ſtream, that they can only be entered by ſteps cut out of the rock. This inconvenience is compenſated in a degree, particularly to a ſtranger, by their romantic ſituation, and by the proſpect of the oppoſite bank, with its towns, villages, monaſteries, and pine-woods.

At Oporto the manners of the people are very much formed on thoſe of the Engliſh, who are here more numerous and conſiderable, in proportion to the other rich inhabitants, than at Liſbon. They have a kind of Caſino in a handſome building, very well regulated, and adapted to bring foreigners together. Not long ago a play-houſe was erected, which, though ill contrived for hearing, attracts a conſiderable number of attendants to the exhibition of Portugueſe plays, performed by tolerably good actors.

The trade of Oporto, which is well-known to conſiſt chiefly of wine, has ſuffered much in conſequence of the war; and the harbour is ill adapted to be a ſtation for ſhips of war, on account of the difficulty of its entrance. Hence French privateers have been almoſt always hovering within ſight of it; and this circumſtance has ruined many houſes in Oporto. In front of the town the river is very deep; two-maſted veſſels can come to the town itſelf, thoſe with three maſts within a quarter of a league, and the large Brazil ſhips unload their cargoes in the road. From a ſtatement made by Link, it appears that the Engliſh trade to Oporto far exceeds that of all other nations. The country and walks round Oporto are very pleaſant and romantic. The rocks which riſe out of the ſand towards the mouth of the river render the entrance into the harbour extremely narrow and very dangerous. The ſea alſo is very boiſterous on theſe coaſts during the rainy ſeaſon, and the river very rapid; and the ſand which is brought down by the ſtream more and more choaks the paſſage. A ſmall fort, called San Joaõ de Fez, near which is a ſmall market-town, covers the entrance; beſides this, on the coaſt to the northward, is a baſtion on the beech; oppoſite to which, on the S. ſide, is alſo a very ſmall fort, called Santa Caterina, with a few other batteries.

Immediately oppoſite to Oporto, on the S. bank of the Duero, is the appearance of a town not much ſmaller than Oporto itſelf. To the weſtward, along the declivity of a hill, are ſeveral detached houſes, forming the market-town of "Gaya," a place remarkable both for its ſituation and name. Here in former times a place called "Cale," ſpoken of by the ancients, is ſaid to have ſtood; but Oporto being afterwards built, as more convenient for ſhips, by the greater depth of water along that bank, it was called "Portus Cale," or the harbour of Cale, whence was derived "Portucal," and at length *Portugal*. Thus, as it is ſaid, from this place the whole kingdom afterwards received its name. Portus Cale was in proceſs of time called "O Porto," (the harbour,) which name the town of Oporto afterwards received. Advancing to the eaſtward, we come to a conſiderable and populous town or villa, called "Villanova do Porto," inhabited by the lower claſſes of people, whereas the rich more generally live in Oporto itſelf. Between Villanova and Gaya, on a ſmall plain along the bank of the river, are the immenſe magazines where wine is kept till it is exported. A monaſtery on a high, and toward the river, very ſteep hill, completes the circle of the view to the eaſtward. It is ſaid that the number of inhabitants at Gaya and Villanova, including the detached houſes, reckoned as part of both places, amounts to about 20,000. The mountains along the N. bank conſiſt of granite in rocks: thoſe along the S. bank of ſtratified granite and mica-ſlate. Traces every where appear of metallic veins of copper pyrites, malachite, and other metals; and along the S. bank, particularly, a copper-mine might be opened with great proſpect of ſucceſs.

The climate of Oporto is in winter damp and foggy, in conſequence of its mountainous and woody ſituation; whence alſo the air is cooler than elſewhere, though it ſeldom freezes. On the contrary, in ſummer, the heat is great, both in this narrow valley and the town, which is ſituated on a ſouthern declivity. Here, as well as along the coaſts of Portugal, regular winds prevail in ſummer, *viz.* in the morning the eaſt wind, veering about noon towards the ſouth, and then to the weſt, from which circumſtance navigation receives many advantages. The ſoil, though well cultivated, is not productive; but oranges are brought from Braga and Barcelos, wine from the Upper Duero, and, in ſhort, all thoſe productions which bear the name of this town are not

grown

grown round it, though they are exported from hence. The gardens round Oporto are beautiful and pleaſant, and the plants of the Cape and of New Holland grow in the open air with gooſeberries, currants, and other fruits of the colder countries of Europe, which are not ſeen round Liſbon.

The common people are more ſuperſtitious, though not more fanatic, than elſewhere. They are reckoned good-humoured, and thefts and robberies are uncommon. Some inſtances of aſſaſſinations with knives, under the influence of jealouſy, occaſionally occur. The politeneſs and friendly diſpoſition of the people are much commended: their language abounds with diminutives to an exceſs that is often ridiculous. Their dreſs ſomewhat differs from that of the ſouthern provinces; wooden ſhoes being here very common, though not found farther towards the ſouth. Oporto is 49 miles N. of Coimbra. N. lat. 41° 11′. W. long 8° 19′. Link's Travels through Portugal.

OPOS, a word uſed by the old medical writers to expreſs the juices of plants, whether flowing ſpontaneouſly, or by means of inciſions. It is uſed by Hippocrates to expreſs the juice of ſilphium, which was called ſimply the juice, by way of eminence, as we call the quinquina bark ſimply the bark. Others have made it ſignify the juice of the fig-tree, and the caprificus, which they had in frequent uſe to curdle their milk.

OPOSSUM, or Possum, in *Zoology*. See Didelphis.

OPOTSCHNA, in *Geography*, a town of Bohemia, in the circle of Konigingratz; 15 miles N.E. of Konigingratz.

OPOUN, one of the Navigators' iſlands, in the South Pacific ocean, ſituated moſt eaſterly as well as moſt ſoutherly of the whole group: it is alſo called "Toomanua." S. lat. 14° 7′. W. long. 169° 7′.

OPPA, a river of Sileſia, which runs into the Oder; 14 miles S.E. of Troppau.

OPPATOW, a town of Moravia, in the circle of Iglau; 14 miles S. of Iglau.

OPPAU. See Troppau.

OPPEAN, a town of Italy, in the department of Benaco; 13 miles S. of Verona.

OPPELN, a principality of Sileſia, bounded N. by Poland, and the principalities of Breſlau, Oels, and Brieg; E. by Poland; S. by the principalities of Ratibor, Jagerndorf, and Troppau; and W. by thoſe of Neiſſe and Brieg. The ſoil is generally ſandy, and many parts are covered with large heaths and foreſts. It contains 27 towns and a few villages.—Alſo, a city of Sileſia, and capital of the above-mentioned principality, ſituated on the Oder, and the ſee of a biſhop: fortified after the ancient manner, and containing two convents, a collegiate church, and a college, which formerly belonged to the Jeſuits. The houſes are moſtly wooden ſtructures, and the inhabitants are Roman Catholics; 45 miles S.E. of Breſlau. N. lat 50° 35′. E. long. 17° 58′.

OPPENAU, a town of Baden; 13 miles E. of Straſburg.

OPPENHEIM, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the diſtrict of Mayence; formerly imperial. The place contains 1674, and the canton 10,735 inhabitants, in 20 communes. The great pariſh church belongs to the Calviniſts, but the Lutherans and Roman Catholics have each their churches. At this place is a good growth of wine; 9 miles S.E. of Mentz. N. lat. 49° 51′. E. long. 8° 20′.

OPPIAN, in *Biography*, a Greek poet and grammarian, was a native of Anarzarba in Cilicia, and flouriſhed in the beginning of the third century. He dedicated two poems, entitled "Halieutica," on fiſhing, and "Cynegetica," on hunting, to the emperor Caracalla; with the latter that ſovereign was ſo much pleaſed, that he gave the author a piece of gold for each line, hence they obtained the name of the *golden verſes*. Both poems have been eſteemed by various modern critics, as well for the force and elegance of the deſcriptions, as for the ingenuity of the thoughts and ſimilies. Oppian likewiſe compoſed a work "On Fowling," with ſome other pieces, which are loſt. He died of the plague at the age of thirty, and was honoured by his townſmen with a ſtatue. The beſt editions of Oppian are thoſe of Ritterhuſius, Lugd. B. 1597; of Schneider, Argent. 1776; and of Bellin de Ballu, Argent. 1785, in two volumes octavo.

OPPIDO, in *Geography*, a town of Naples, in Calabria Ultra; the ſee of a biſhop; deſtroyed by an earthquake in the year 1783; the preſent town is built three miles from the former, which contained about 3000 inhabitants, 1200 of whom periſhed on that occaſion. The loſs of the province, by and in conſequence of this calamity, included about 32,000 perſons. The town is ſituated 27 miles N.E. of Reggio. N. lat. 38° 18′. E. long. 16° 23′.—Alſo, a town of Naples, in Baſilicata; five miles S.S.E. of Acerenza.

OPPIDONEON, Sinaab, in *Ancient Geography*, a town and colony of Africa, in Mauritania Cæſarienſis, where the emperor Claudius formed an eſtabliſhment of veterans. It was ſituated on the ſouthern bank of the river Chinalap, N. of the mountains denominated Zalacus.

OPPIDUM Novum, a town of Gallia Aquitanica, between Beneharnum and Aquæ Convenarum. Anton. Itin. —Alſo, a town of Africa, in Mauritania Tingitana, between Tremulæ and Ad Novas. Id.

OPPIETO, in *Geography*, a town of the iſland of Corſica; eight miles N.N.E. of Ajazzo.

OPPILATION, in *Medicine*, the act of obſtructing or ſtopping up the ducts, or paſſages of the body, by redundant or peccant humours.

The word is chiefly uſed for obſtructions of the lower belly.

Viſcid, heavy foods, difficult of digeſtion, are oppilative; they do not paſs off well, but ſtop in the mouth of the veſſels.

OPPILATIVE. See Deoppilative.

OPPONENS Pollicis, in *Anatomy*, a muſcle of the thumb: it is part of the thenar of Winſlow, and the carpo-metacarpien of Dumas. It lies on the firſt bone of the thumb, immediately under the abductor, and extends from the carpus to the firſt phalanx of the thumb. It ariſes from the annular ligament, and from the os trapezium; its fibres are directed obliquely outwards, and terminate in the whole length of the outer edge of the firſt phalanx of the thumb. It is covered externally by the abductor; and it covers the joint of the thumb with the os trapezium, and the ſurface of the firſt phalanx: the flexor brevis lies along its inner edge, and is often very cloſely connected to it. This muſcle draws the firſt phalanx acroſs the palm, ſo as to bring the thumb into oppoſition to the other fingers, as when we graſp a ſpherical body in one hand, or, in a ſmaller degree, when we hold a pen, pencil, &c.

OPPONENT, a perſon who withſtands or oppoſes another. The term is chiefly uſed in ſpeaking of ſcholaſtic or academic diſputes or exerciſes, where a perſon who oppoſes a theſis, or impugns it by his objections, is called *opponens*, opponent.

OPPOSER, Foreign. See Foreign *Oppoſer*.

OPPOSITES, Opposita, among *Logicians*, are such things as differ among themselves; but so as not to differ in like manner from some third.

By which circumstance, *opposites* differ from *disparates*.

The schoolmen reckon four kinds of opposites; *viz.* relatively, contrarily, privatively, and contradictorily opposites.

Either, say they, the opposition is between ens and non ens; if the former, it is either with a dependent ens, which makes a relative opposition, the lowest of all; or an independent one, which is a contrary opposite: if a non ens, it is either with a non ens secundum quid, which is privative; or with a non ens simply, which is the highest opposition.

Opposites, *Oppositа*, complexly taken, are propositions that clash with each other. As, man is an animal; and man is not an animal.

Opposite *Angles*. See Angle.

Opposite *Cones* denote two similar cones, vertically opposite, that is, having the same common vertex, as well as the same axis. See Cone.

Opposite *Sections* are two hyperbolas made by cutting two opposite cones by the same plane. See Hyperbola.

OPPOSITION, in *Geometry*, the relation of two things, between which a line may be drawn perpendicular to both.

Opposition, in *Logic*, the quality of disagreement between propositions which have the same subject, and the same attribute.

Opposition is said, by logicians, to be either *complex* or *incomplex*.

Incomplex, or *simple* opposition, is the disagreement of two things, which will not suffer each other to be in the same subject.

Thus heat is opposed to cold, sight to blindness, &c. Which opposition has already been observed to be of four kinds.

Complex opposition is defined, by Aristotle, to be the affirming and denying the same predicate of the same subject, not taken equivocally, but for the same, in the same manner, and at the same time; as, Socrates is learned; and Socrates is not learned.

The later schoolmen, deviating from their master, define opposition an affection of enunciations, whereby two absolute propositions, the same extremes being supposed in the same order and number, and understood without any ambiguity, of the same thing, oppose each other, either in respect of quantity or of quality, or of both. According to the former definition, there are three species of opposition, *contrary*, *subcontrary*, and *contradictory*: according to the second, a fourth species is admitted, viz. *subaltern*.

To know how and wherein propositions are opposite, they must be compared, in quantity and quality, all the ways in which they can be compared. If they be opposite both in quality and quantity, *i. e.* if the one be affirmative, and the other negative; the one universal, the other particular; they are said to be contradictory; *v. gr.* no pleasure is allowed; some pleasure is allowed.

If they be only opposite in quality, and not in quantity, they are called *contraries*, if universal: and *subcontraries*, if particular; *v gr.* all use of wine is evil; no use of wine is evil. Some means of preserving reputation are allowed; some means of preserving reputation are not allowed.

If the propositions be only opposite in quantity, they are called *subalterns*: *v. gr.* every man is liable to sin; some man is liable to sin. But this last is no proper opposition; inasmuch as the universal proposition always includes the particular one.

Single propositions, which can only be opposed in quality, are reducible to contrary ones.

The essential properties of propositions, considered with regard to their opposition; are, 1. That of two contradictory propositions, there is one always true, and another false. 2. Two contradictory propositions can never be both true; but may be both false. 3. Subcontrary propositions may be all true at the same time; as happens when the attribute is accidental to the subject: but when it is essential to it, the one is true, the other false. 4. Subalterns may be either true or false at the same time; or the one may be true, the other false. If the attribute be essential to the subject, the subaltern affirmatives are true, and the negatives false; but if the negatives deny the subject an attribute incompatible with the subject, they will be both true. When the attribute is accidental to the subject, the universal subaltern is ordinarily false, and the particular one true.

Opposition, in *Rhetoric*, denotes a figure, whereby two things are joined together, which appeared incompatible; as when Horace says, a *wise folly*.

In Bouhours's notion, this figure, which seems to deny what it establishes, and contradicts itself in appearance, is very elegant. See Antithesis.

Opposition, in *Astronomy*, is that aspect or situation of two stars or planets, wherein they are diametrically opposite to each other, or 180°, that is, a semicircle, apart.

When the moon is diametrically opposite to the sun, so that she shews her whole illumined face; she is said, with regard to the sun, to be in opposition; and she is then said to be *in her full*, and shines all night long. See Moon and Phases.

Eclipses of the moon never happen but when she is in opposition with the sun, and when they both meet in or near the nodes of the ecliptic.

Mars in his opposition to the sun is nearer the earth than he is to the sun.

OPPS, in *Geography*, a village of America, in Northampton county, Pennsylvania; six miles S.E. of Bethlehem.

OPPURG, a town of Saxony, in the circle of Neustadt, which has a citadel, and was formerly fortified with walls and towers; four miles W.S.W. of Neustadt.

OPSA, a town of Lithuania, in the palatinate of Wilna; 12 miles S.S.W. of Braslau.

OPSAL, a town of Norway, in the province of Aggerhuus; 40 miles N. of Konswinger.

OPSICELLA, in *Ancient Geography*, a town of Spain, in Cantubria; built, according to Strabo, by the companions of Antenor, and named by him.

OPSIUKOVA, a town of Russia, in the government of Novgorod, on the Tchegodo; 80 miles E.N.E. of Novgorod.

OPSLO. See Christiania.

OPSO, a town of Istria; seven miles E.N.E. of Cape d'Istria.

OPSONOMUS, in *Antiquity*, a magistrate of Athens, of whom there were two or three; chosen out of the senate or council.

Their office was to inspect the fish-market, and to take care that every thing was done in order, and according to the laws.

OPTATIVE, in *Grammar*, the third mood in the conjugations of verbs, serving to express an ardent desire or wish for any thing.

Instead of a particular mood, or a particular set of inflexions to express this desire, the English, Latins, &c. express it by an adverb of wishing prefixed to it. The Latins

by *utinam*; the French by *plut à Dieu*; and the Engliſh by *would to God*, &c.

In theſe languages, ſetting aſide the adverb, the optative is the ſame with the ſubjunctive; the inflexion of the verb, which make what we call the *moods*, being the ſame in both.

Indeed, in the Greek, the wiſh is expreſſed by a particular inflexion, thence called optative; and in the French, Spaniſh, and Italian, there is ſomething like it; their triple ſenſes ſerving the ſame purpoſe. But the optative mood may be ſafely retrenched from the Latin and Engliſh. See MOOD.

OPTERIA, formed from οπτομαι, *I ſee*, among the *Ancients*, preſents made to a child the firſt time a perſon ſaw it.

OPTERIA was alſo uſed for the preſents which the bridegroom made his bride when ſhe was conducted to him; this being the firſt time he ſaw her. See Barthol. de Puerp. vet.

OPTIC, or OPTICAL, ſomething that relates to *viſion*, or the ſenſe of ſeeing. See VISION.

OPTIC *Angle*. See ANGLE.

OPTIC *Axis*. See AXIS.

OPTIC *Chamber*. See CAMERA *Obſcura*.

OPTIC *Glaſſes*, are glaſſes ground either concave or convex; ſo as either to collect or diſperſe the rays of light; by means of which viſion is improved, and the eye ſtrengthened, preſerved, &c.

For the manner of grinding and poliſhing optic glaſſes; ſee GRINDING, POLISHING, GLASS, &c. For their phenomena, ſee LENS, MIRROR, &c.

The principal among optic glaſſes are teleſcopes, microſcopes, ſpectacles, reading glaſſes, magic lanterns, &c. See the conſtruction and uſe of each under its proper article, TELESCOPE, MICROSCOPE, SPECTACLE, MAGIC *Lantern*, &c.

OPTIC, or *Optical Inequality*, in *Aſtronomy*, is an apparent irregularity in the motions of far diſtant bodies; ſo called, becauſe not really in the moving bodies, but ariſing from the ſituation of the ſpectator's eye; ſo that if the eye were in the centre, it would always ſee the motions uniform.

The optical inequality may be thus illuſtrated: ſuppoſe a body revolving in the periphery of a circle A B D E F G Q P (*Plate* XV. *Optics*, *fig.* 22.) and moving through equal arcs A B, B D, D E, E F, in equal times; and ſuppoſe the eye in the plane of the ſame circle, but at a diſtance from it, viewing the motion of the body from O: when the body goes from A to B, its apparent motion is meaſured by the angle A O B, or the arc H L, which it will ſeem to deſcribe. But in an equal time, while it moves through the arc B D, its apparent motion will be determined by the angle B O D, or the arc L M, which is leſs than the former arc H L. And when arrived at D, it will be ſeen at the point M of the line N L M. But it ſpends the ſame time in deſcribing D E, as it does in A B or B D; and when arrived at E, it is ſtill ſeen at M; appearing ſtationary in all the ſpace from D to E. When it arrives at F, the eye will ſee it in L; and at G, it will appear at H; ſo it will ſeem to have gone retrograde: and, laſtly, from Q to P, it will again appear ſtationary.

OPTIC *Nerves*, in *Anatomy*, the ſecond pair of nerves, ſpringing from the crura of the medulla oblongata, and paſſing thence to the eye. See NERVOUS *Syſtem*. See alſo VISION.

OPTIC *Nerves, Diminiſhed Senſibility of*. See GUTTA *Serena*.

OPTIC *Penſil*. See PENCIL *of Rays*.

OPTIC *Place* of a ſtar, &c. See PLACE.

OPTIC *Pyramid*, in *Perſpective*, is the pyramid whoſe baſe is the viſible object, and its vertex in the eye; formed by rays drawn from the ſeveral points of the perimeter to the eye.

Hence alſo may appear what is meant by optic triangle.

OPTIC *Rays* are particularly uſed for thoſe with which an optic pyramid, or optic triangle, is terminated.

OPTICS, OPTICA, is properly the ſcience of direct *viſion*; which ſee.

OPTICS is alſo uſed, in a larger ſenſe, for the ſcience of viſion, or viſibles in general.

In which ſenſe, optics includes *catoptrics*, and *dioptrics*: and even *perſpective*; which ſee reſpectively.

OPTICS, in its more extenſive acceptation, is a mixed mathematical ſcience, which explains the manner by which viſion is performed in the eye; treats of ſight in the general; gives the reaſons of the ſeveral modifications or alterations which the rays of light undergo in the eye; and ſhews why objects appear ſometimes greater, ſometimes ſmaller, ſometimes more diſtinct, ſometimes more confuſed, ſometimes nearer, and ſometimes more remote. In this extenſive ſignification, it is conſidered by ſir Iſaac Newton in his admirable work called "Optics."

Optics makes a conſiderable branch of natural philoſophy; both as it explains the laws of nature, according to which viſion is performed; and as it accounts for abundance of phyſical phenomena, otherwiſe inexplicable. For what can be determined about light, colours, tranſparency, opacity, meteors, the rainbow, parhelia, &c. but on the principles of optics? What about the nature of the ſtars? The ſtructure of the mundane ſyſtem? The motions of the planets? The eclipſes of the luminaries? &c. Optics, therefore, makes a conſiderable part of aſtronomy.

It was the opinion of Pythagoras, that viſion is cauſed by particles continually flying from the ſurfaces of bodies, and entering the pupil of the eye: whereas Empedocles and Plato ſuppoſed, that the cauſe of viſion is ſomething emitted from the eye, which meeting with ſomething elſe that proceeds from the object, is thereby reflected back again. But though the Platonic philoſophers were miſtaken as to the progreſs of viſion, they were acquainted with two very important and fundamental principles of this ſcience; *viz.* that light, from whatſoever it proceeds, is propagated in right lines, differing in this reſpect from ſound; and that when it is reflected from the ſurfaces of poliſhed bodies, the angle of incidence is equal to the angle of reflection.

Ariſtotle, amidſt the variety of other objects that engaged his attention, did not overlook the ſcience of optics, though many of his obſervations were fanciful and erroneous. Thus we find, that he maintained, in oppoſition to Empedocles, that light is incorporeal; conceiving that if it were not a mere quality, but a real ſubſtance, the motion of it could not be inſenſible, in paſſing from the eaſt to the weſt, though it might eſcape our notice in a ſmaller diſtance. His remarks on the rainbow, halos, and other phenomena of a ſimilar nature, which were claſſed by the ancients under the denomination of meteors, though, in ſome reſpects, blended with error, are nevertheleſs, in other reſpects, juſt and true, and have led to a more unexceptionable and philoſophical account of the cauſes that produce them, and the various circumſtances that attend them. Indeed, the knowledge of the ancients in this department of ſcience was very imperfect and limited; though they ſeem to have been acquainted with the refraction as well as the reflexion of light. It appears, that the ancient geometricians contented themſelves.

ſelves with deducing a ſyſtem of optics from the two principles above-mentioned: and the treatiſe of optics, which has been aſcribed to Euclid, is employed about determining the apparent ſize and figure of objects from the angle under which they appear, or which the extremities of them ſubtend at the eye, and the apparent place of the image of an object reflected from a poliſhed mirror; which he fixes at the place where the reflected ray meets a perpendicular to the mirror drawn through the object. But this work of the ancient mathematician is ſo imperfect, and ſo inaccurate, that moſt perſons have heſitated in aſcribing it to this celebrated author. The latter part of Euclid's work is employed in inveſtigating the phenomena of plane, convex, and concave mirrors. The magnifying power of concave mirrors is mentioned both by Seneca and Pliny. The effects of burning-glaſſes were obſerved by the ancients; and the power of concave mirrors in this reſpect is taken notice of by Euclid in the treatiſe we have mentioned. It has been ſaid, and very generally allowed, that Archimedes wrote a treatiſe on the ſubject of burning mirrors, though it be not now extant. From the time of Euclid to Seneca, who repeats the crude ſentiments of Ariſtotle, together with ſome of his own, concerning the rainbow, we find nothing worthy of being particularly detailed on the ſubject of optics. Ptolemy, who lived 150 years after Chriſt, wrote a treatiſe of optics, which is loſt; but from the accounts of others it is known, that he treated of aſtronomical refractions. After Ptolemy there occurs a great chaſm in the hiſtory of optics, as well as other branches of mathematics and philoſophy, which were cultivated chiefly by the Arabs during the dark ages of Europe. The firſt Arabian writer of optics, of whom we have any account, is Al Farabi, who flouriſhed 900 years after Chriſt, but of his work we know nothing. The treatiſe of Ebn Haithem, who in the year 1000 wrote more largely on this ſubject, and who treated diſtinctly of direct, reflected, and refracted viſion, and alſo of burning mirrors, is loſt. The only work of the Arabian philoſophers that remains is that of Alhazen, who flouriſhed in the 12th century; and his treatiſe of optics is well worthy of attention. He gives a tolerable deſcription of the eye, and diſcourſes largely concerning the nature of viſion, maintaining that the cryſtalline humour of the eye is of principal uſe for this purpoſe, without conſidering it as a lens, and aſſerting that viſion is not completed, till the ideas of external objects are conveyed by the optic nerves to the brain. He accounts for ſingle viſion by two eyes, by ſuppoſing that when two correſponding parts of the retina are affected, the mind perceives but one image: and he treats much at large of optical deceptions both in direct viſion, and alſo in viſion by reflected and refracted light. Alhazen alſo inquired concerning the nature of refraction more than any of the ancient writers; and from aſtronomical obſervations he deduced ſeveral properties of atmoſpherical refraction: firſt of all advancing, that the ſtars are ſometimes ſeen above the horizon by means of refraction, when they are really below it. This obſervation was confirmed by Vitellio, B. Waltherus, and Tycho Brahe. Alhazen alſo obſerved, that refraction contracts the diameters and diſtances of the heavenly bodies, and that it is the cauſe of the twinkling of the ſtars: though it is probable that neither he nor Vitellio knew any thing of its juſt quantity. About the year 1500, great attention was paid to this ſubject by Bernard Walther, Mæſtlin, and others, but chiefly by Tycho Brahe. Vitellio, a native of Poland, illuſtrated Alhazen's optics, in a treatiſe publiſhed in 1270. This work contains every thing valuable in that of Alhazen, and it is digeſted in a much more methodical and intelligible manner. He notices the light that is loſt by reflection and refraction, by reaſon of which all objects appear leſs luminous. The reſult of his experiments on the refractive powers of air, water, and glaſs, correſponding to different angles of incidence, he reduced into a table. In his account of the horizontal moon, he agrees with Alhazen, obſerving, that, in the horizon, the ſky ſeems to touch the earth, and appears much more diſtant from us than in the zenith, on account of the intermediate ſpace containing a greater variety of objects upon the viſible ſurface of the earth. He aſcribes the twinkling of the ſtars to the motion of the air, in which the light is refracted; and he ſhews that refraction, as well as reflection, is neceſſary to form the rainbow. He defines the colours of the rainbow to be three, and makes many other obſervations on its phenomena. Vitellio attempts to explain refraction, or to aſcertain the law of it, and he conſiders the foci of glaſs ſpheres, and the apparent ſize of objects ſeen through them; but Montucla ſays, that he is not at all accurate upon any of theſe ſubjects. Ten years after the publication of Vitellio's work, Peccam, archbiſhop of Canterbury, wrote a treatiſe of direct optics, which was then called perſpective; but without making any addition to the exiſting ſtock of optical knowledge. His treatiſe is ſaid to be conciſe and judicious, and to contain, among other things, a very clear and diſtinct account of the reaſon why the ſky near the horizon appears more diſtant from us than at any other place. As contemporary with Vitellio and Peccam, was Roger Bacon, who frequently quotes Alhazen on the ſubject of optics, and who does not ſeem, as far as reſpects the theory of optics, to have much improved on the Arabian writer. From the writings of Alhazen, and Bacon's obſervations and experiments, ſome monks, it is probable, gradually ſucceeded in the conſtruction of ſpectacles. The uſe of concave as well as convex glaſſes for the aſſiſtance of viſion, whoever might have firſt ſuggeſted it, was particularly explained by Maurolycus. Bacon made approaches, to ſay the leaſt of them, towards the diſcovery and actual conſtruction of teleſcopes and microſcopes. To Maurolycus, teacher of mathematics at Meſſina, we are indebted for ſome capital improvements in the ſcience of optics. This writer, in his treatiſe "De Lumine et Umbra," publiſhed in 1575, demonſtrates that the cryſtalline humour of the eye is a lens, that collects the rays of light that iſſue from external objects, and throws them upon the retina, in which is the focus of each pencil: and hence he was led to diſcover the reaſon why ſome perſons are ſhort-ſighted and others long-ſighted; and why the former are relieved by concave glaſſes, and the latter by thoſe that are convex. But he does not ſeem to have found, that the rays of light iſſuing, in pencils, from every point of an object, make a real image of it upon the retina. About the ſame time that Maurolycus made ſuch great advances towards the diſcovery of the nature of viſion, Johannes Baptiſta Porta, of Naples, invented the camera obſcura, an account of which he publiſhed in his "Magia Naturalis," about the year 1560, when he was not quite fifteen years old. This work was republiſhed thirty years after, with great enlargements. On its firſt publication, it was immediately tranſlated into Italian, French, Spaniſh, and Arabic, and paſſed through many editions in various countries. Porta's diſcovery ſuggeſted a hint to Kircher, of which he availed himſelf by the conſtruction of the magic lantern, doing that in the night, and in many reſpects more conveniently, which Porta exhibited in the day. Notwithſtanding Porta's experiments with the camera obſcura, and ſeveral juſt concluſions which he deduced from them, he erroneouſly conceived that the cryſtalline humour received

the images of objects; and Kepler was the perſon, who, in 1604, firſt obſerved that the retina is the tablet on which the images of external objects are depicted. Kircher's diſcoveries are contained in his work entitled "Ars magna Lucis et Umbræ." But our limits will not allow our particularizing more, either of his or of Porta's improvements in optics. Referring to the article RAINBOW an hiſtorical account of obſervations relating to this phenomenon by Maurolycus, B. Porta, Fletcher of Breſlau, and Antonio de Dominis, and to the articles TELESCOPES and MICROSCOPES the diſcoveries relating to theſe inſtruments, we ſhall proceed to conſider the ſervices done to the ſcience of optics by the famous John Kepler. He not only explained the rationale of the teleſcope which he found in uſe, but pointed out methods of conſtructing others of ſuperior powers, and more commodious application. To him we are principally indebted for an explanation of the doctrine of refraction through mediums of different forms, though ſomething of this kind had previouſly been done by Maurolycus; and thus he led the way to the illuſtration of the rationale of teleſcopes and microſcopes. Beſides the doctrine of lenſes, and the rationale of teleſcopes, &c. depending upon it, we are indebted to Kepler for his attention to ſeveral other branches of optical ſcience, particularly the buſineſs of refraction, and the nature of viſion. The ſame age that produced Kepler was ſtill more diſtinguiſhed by Galileo, who threw new light upon almoſt every ſubject of philoſophical inquiry. Beſides the part he took in the conſtruction and uſe of teleſcopes, which we ſhall more particularly notice under that article, he firſt conceived the thought of meaſuring the velocity of light, and he gives a particular deſcription of his contrivance for this purpoſe in his treatiſe on mechanics.

Although Des Cartes was very eminent in the ſcience of optics, he does not ſtand ſingle in the period at which he lived. Beſides Snellius, who led the way to the diſcovery of the great law of refraction, he had other illuſtrious contemporaries; particularly the famous Scheiner, a Jeſuit, who died in the ſame year with Des Cartes. He carried into execution the ſchemes of Kepler, for conſtructing teleſcopes upon plans different from that of the original or Galilean one; and ſhares with Galileo the merit of diſcovering the ſpots of the ſun. His treatiſe entitled "Oculus" is very valuable, and abounds with ingenious and important illuſtrations of the nature of viſion. Gaſſendi, alſo a contemporary of Des Cartes, wrote largely on the ſubject of light, and the natural phenomena which depend upon it; but he adhered cloſely to the ſyſtem of Epicurus, in oppoſition to that of Ariſtotle, maintaining the materiality of light, and aſſerting that bodies are viſible by means of particles continually detaching themſelves from their ſurfaces. Gaſſendi, however, made no particular diſcovery in optics: and he is to be ranked rather among the ſchoolmen than the philoſophers. Du Hamel, the firſt ſecretary to the Royal Academy of Sciences at Paris, in his "Aſtronomia Phyſica," publiſhed in 1681, examined the opinions of Epicurus, as defended by Gaſſendi, and the Carteſian hypotheſis; and after a laboured refutation of them both, pleads ſtrongly in favour of the Ariſtotelian doctrine of light. We might here alſo mention Aguilonius, a Jeſuit of Bruſſels, who publiſhed a large treatiſe on optics in 1613. But Athanaſius Kircher, who was one of the ableſt philoſophers and mathematicians of the age in which he lived, merits peculiar notice. He was about the ſame age with Des Cartes, but outlived him thirty years. His large and magnifice t work, already mentioned, and entitled "Ars magna Lucis et Umbræ," muſt, at the time in which it is written, have been conſidered as a very capital performance; and though this author diſcovered no new property of light, he contributed very much to the extenſion and improvement of the ſcience of optics. Kircher took great pains in forming, from natural experiments, a table of the angles of refraction, correſponding to any given angle of incidence, even to a minute of a degree, with reſpect to air and water; and he obſerved the degrees with regard to wine, oil, and glaſs. This table is contained in the work already cited. At length the diſcovery of the true law of refraction was made, in part, by Willebrod Snellius, profeſſor of mathematics at Leyden. He did not live to publiſh it himſelf, but it was communicated to ſeveral perſons before it appeared in the writings of Des Cartes, who publiſhed it under a different form, without acknowledging his obligations to Snellius, whoſe papers, as Huygens aſſures us, from his own knowledge, Des Cartes had ſeen. Snellius was led to the important diſcovery, not by any reaſoning á priori, but by experiments. The diſcovery was, that the co-ſecants of the angles of incidence and refraction are always in the ſame ratio; if the medium be air and water, the ratio is 4 to 3, if air and glaſs, it is 3 to 2 nearly. Des Cartes publiſhed this law as the reſult of his own inquiries into the nature of reflection and refraction. But he gives it under a different form from that of Snellius, and, in general, a more commodious one; for, according to him, the ſine of the angle of refraction always bears the ſame proportion to the ſine of the angle of incidence. Des Cartes ſeems to have been the firſt perſon who attempted to explain the cauſe of refraction, which he did by the reſolution of forces, on the principles of mechanics: ſuppoſing that light paſſes with more eaſe through a denſe medium than a rare one. The truth of this explanation was queſtioned by M. Fermat; who, in oppoſition to Des Cartes, aſſerted that light ſuffers more reſiſtance in water than in air, and more in glaſs than in water; and he maintained, that the reſiſtance of different mediums, with reſpect to light, is in proportion to their denſities. M. Leibnitz adopted the ſame general idea: for the reſult of their mode of reaſoning, ſee REFRACTION. Dechales explained the law of refraction by another hypotheſis, which was adopted by Dr. Barrow, if he was not the author of it: for an account of this alſo we refer to REFRACTION.

One of the moſt conſiderable improvements in optical knowledge made by Des Cartes was his explication of the *rainbow*; which ſee. Scheiner made ſeveral important obſervations relating to viſion at this period; completing the diſcovery that viſion is performed by means of the images of external objects upon the retina. By cutting away the coats of the back part of the eyes of ſheep and oxen, and preſenting ſeveral objects before them, within the uſual diſtance of viſion, he ſaw their images diſtinctly and beautifully painted upon the naked retina. He did the ſame with the human eye; and exhibited this curious experiment at Rome in the year 1625. Scheiner particularly notices the correſpondence between the eye and the camera obſcura, and explains a variety of methods to make the images of objects erect. As to the images of objects being inverted in the eye, he acquieſces in the reaſon for it aſſigned by Kepler, *viz.* that the mind traces the progreſs of the rays to the pupil, and refers them to that part of the object from which they, at that place, ſeemed to have proceeded. That the pupil of the eye is enlarged, in order to view remote objects, and that it is contracted while we are viewing thoſe that are near, is a fact with which Scheiner was well acquainted, and which he proved by experiments, and illuſtrated by figures. Scheiner took conſiderable pains in aſcertaining the denſity and refractive power of all the humours of the eye; and concludes, that the aqueous humour does not differ much

from water in this reſpect, nor the cryſtalline from glaſs, and that the vitreous humour is a medium between them both. He alſo traced the progreſs of the rays of light through all the humours of the eye, and after diſcuſſing every hypotheſis concerning the ſeat of viſion, demonſtrates that it is the retina, ſhewing that this was the opinion of Alhazen, Vitellio, Kepler, and all the moſt eminent philoſophers. Des Cartes well explains the natural methods of judging of the magnitudes, ſituations. and diſtances of objects by the direction of the optic axes; comparing it to a blind man's judging of the diſtance and ſize of an object, by feeling at it with two ſticks of a known length, when the hands in which he holds them are at a known diſtance from each other. Under the article VISION we ſhall mention ſome other obſervations of this ingenious philoſopher that pertain to this ſubject.

Some time before the age of Des Cartes, and alſo during his time, philoſophers began to ſpeculate concerning the poſſibility of what Archimedes is ſaid to have effected with burning mirrors, in deſtroying the fleet of Marcellus; and obſerving that the focal diſtance of concave ſpeculums was much too ſmall for the purpoſe, the ſtory was diſcredited, and rejected as a fable, particularly by Des Cartes. Kircher, and his pupil Schottus, however, thought the ſubject worthy of a more particular inveſtigation, eſpecially as Proclus is ſaid to have deſtroyed a fleet at Conſtantinople by the ſame means. Kircher, with a view of terminating the diſpute, made a number of experiments; and at length determined to try the effect of many plane mirrors. Accordingly he erected a frame, on which he placed five of theſe mirrors, of the ſame ſize, and ſo diſpoſed as to throw the rays that were reflected from them, upon the ſame place, at the diſtance of more than 100 feet; and theſe five mirrors produced ſo great a degree of heat, that he had no doubt but that, by multiplying them, he could have ſet fire to inflammable ſubſtances at a greater diſtance. A drawing of this machine may be ſeen in Kircher's "Ars magna Lucis et Umbræ." Intent upon this ſubject, Scheiner, after many trials, made a voyage to Syracuſe, in company with Scottus, to take a view of the place and of the ſuppoſed tranſaction; and they both concluded that the galleys of Marcellus could not have been more than 30 paces from Archimedes. See BURNING *Glaſſes*.

The controverſy concerning the nature of light was revived at this period by the hypotheſis of Des Cartes, who maintained that light is neither a ſubſtance, as Epicurus and ſome others had ſuppoſed, nor yet a mere property of bodies, as Ariſtotle conceived; but the motion of a ſubtle fluid, communicated inſtantaneouſly by the preſſure of a luminous body. Inſtead of the perfectly ſolid globules, in the motion of which Des Cartes thought that light conſiſted, Malebranche ſubſtituted fluid vortices, and ſuppoſed that every impreſſion communicated to any one of them is immediately tranſmitted to thoſe that are contiguous to it, ſo that the propagation of light is ſimilar to that of ſound. The later Carteſians in general ſuppoſed, that the fluid by which light is tranſmitted is elaſtic, and M. Huygens further modified the Carteſian hypotheſis, imagining the waves of light to ſpread, not circularly, but in ellipſes; and upon this ſuppoſition he endeavoured to explain the phenomena of Iſland cryſtal. Des Cartes was embarraſſed by his hypotheſis concerning light in forming his ideas concerning colours. He advanced that light is affected by two kinds of motion, direct and circular. When the circular motion is quicker than the direct, the colour, he ſays, is red; if the direct be quicker, it is blue; but if they be equal, it is yellow; and out of theſe three colours it was long the opinion of many philoſophers, that all the reſt were formed, by different proportions in their mixture. Notwithſtanding this embarraſſment and error with reſpect to the nature of light, and colours, he juſtly diſtinguiſhes between black and white; obſerving that the former ſuffocates, or extinguiſhes the rays that fall upon it; whereas the latter reflects them. Kepler thought that black objects became hot ſooner than white ones, becauſe the former are of a more dry and inflammable nature. While Kircher was at Rome in 1639, he had an opportunity of examining a report that was current concerning the cameleon; *viz.* that it could aſſume the colour of any object near which it was placed, except thoſe that were white or red; he found that there was no grounds for the exception of theſe two colours; this power he aſcribes to the imagination of the animal, as it loſes it when it is dead. Kircher was the firſt who obſerved the remarkable properties of the infuſion of lignum nephriticum, the optical phenomena of which have been the ſubject of various diſcuſſion from his time to that of ſir Iſaac Newton, who firſt explained them ſatisfactorily. In the ſubſequent period, ſeveral philoſophical ſocieties were formed, which very much contributed to the improvement of optics, as well as other ſciences. The perſons who diſtinguiſhed themſelves at this time were Dr. Hooke, ſecretary to the Royal Society, father Grimaldi in Italy, De la Hire, M. Marriotte, M. Perrault, among the French, and particularly M. Huygens, who compoſed a treatiſe of Dioptrics, of which Newton always profeſſed a very high opinion. Otho Guericke and father Cherubin alſo deſerve mention. The greateſt diſcovery that was made during the period to which we have now advanced in the hiſtory of optics was the velocity with which light is tranſmitted. Galileo attempted to meaſure it, but failed; the academy del Cimento purſued the ſubject according to the mode propoſed by Galileo; need we be ſurpriſed at their want of ſucceſs? At length the object was accompliſhed by Roemer. (See LIGHT.) The honourable Mr. Boyle made a variety of experiments in order to diſcover the firſt principles and cauſes of colours, and the conſtitution of bodies on which they depend; but the enumeration of them would require a detail, for which we have not room. The facts concerning lignum nephriticum, ſuggeſted by Kircher, were fully aſcertained by Mr. Boyle, who alſo corrected ſeveral of the haſty obſervations of Kircher concerning the colours that appear in the infuſion of this ſubſtance. In this tincture he obſerved the difference between reflected and tranſmitted light. The principal phenomena of this infuſion are eaſily explained by the Newtonian doctrine of the different refrangibility and reflexibility of the rays of light, and the diſpoſition of particular bodies to reflect ſome kinds of rays and to tranſmit others; ſo that if the reflected light fall upon the eye, they ſhall appear to be of one colour, when by the tranſmitted light they appear to be of another. The firſt diſtinct account of the colours exhibited by thin plates, of various ſubſtances, occurs among the obſervations of Mr. Boyle. The ſubject was purſued by Dr. Hooke; and he was the firſt to obſerve, if not to deſcribe, the beautiful colours that appear in thin plates of Muſcovy glaſs. Mr. Haukſbee about this time made many experiments by means of a priſm for aſcertaining the refractive powers of different fluids; and he drew up a table that exhibited their ſpecific gravities, the angles at which they were obſerved, and the ratio of refraction. Dr. Hooke firſt ſuggeſted the idea of making allowance for the effect of the refraction of light in paſſing from the higher and rarer, to the lower and denſer region of the atmoſphere, in the computed height of mountains; and thus he accounts for the difference among authors with regard to the height of ſeveral very high hills. For an account of the diſcovery of the *inflection* of light we refer

refer to that article, and for the ſeat of viſion, &c. to CHOROIDES, EYES, RETINA, and VISION.

The firſt perſons who diſtinguiſhed themſelves in grinding teleſcopic glaſſes were two Italians, *viz.* Euſtachio Divini at Rome, and Campani, of ſuperior fame, at Bologna. For the hiſtory of the invention and improvements of the refracting and reflecting teleſcopes, and microſcopes, ſee TELESCOPE and MICROSCOPE. Of all the diſcoveries that have been made at any time, concerning the nature of light and colour, thoſe of ſir Iſaac Newton are pre-eminent, and they are compriſed in his "Optics." The principal of them were communicated to the Royal Society, ſeven or eight years after they were made, in a letter to the ſecretary Mr. Oldenburgh, dated Cambridge, Jan. 18. 1672. (See COLOUR and REFRANGIBILITY.) See alſo REFRACTION and REFLEXION. Sir Iſaac Newton's improvement of teleſcopes will appear under that article. The obſervations that were made in reference to the Bolognian phoſphorus will be detailed under PHOSPHORUS, &c. and the concluſions deduced from them with regard to the materiality of light will be found under LIGHT, &c. The velocity of light, firſt aſcertained by Roemer, was farther inveſtigated by Dr. Bradley and Mr. Molyneux, in 1725. (See LIGHT.) At and after this period the ſcience of optics received great improvements from the obſervations and experiments of Mr. Melville, the marquis de Courtivron, M. Boſcovich, M. Clairaut, M. Muſchenbroeck, M. Bouguer, M. Buffon, the Abbé Mazeas, Melville, M. Du Tour, M. Euler, Mr. Dollond, the duke de Chaulnes, Mr. Lambert, Mr. Canton, M. de la Hire, Dr. Porterfield, Dr. Jurin, Dr. Motte of Dantzic, biſhop Berkeley, Dr. Barrow, Mr. Robins, Dr. Smith, Delaval, Mr. Michell, &c. &c.; but our limits will not allow our particularly enumerating them in this place; and it is the leſs neceſſary to do it, as they occur under appropriate articles in various parts of the Cyclopædia.

We ſhall cloſe this article with obſerving that we have an excellent and comprehenſive work on Optics, by Dr. Smith, 4to; another by Mr. Harris, 4to.; and an elaborate Hiſtory of the preſent State of Diſcoveries relating to Viſion, Light, and Colours, by Dr. Prieſtley, 4to. 1772.

But as the ſcience of optics conſtitutes a very diſtinguiſhing branch of natural philoſophy, we have treatiſes of optics in every comprehenſive ſyſtem of philoſophy; ſo that it would be endleſs to enumerate the various writers on this ſubject.

From optics likewiſe ariſes perſpective, all the rules of which have their foundation in optics. Indeed Tacquet makes perſpective a part of optics; though John, archbiſhop of Canterbury, in his "Perſpectiva Communis," calls optics, catoptrics, and dioptrics, by the name *perſpective*.

This art, for ſo it ſhould be conſidered rather than as a ſcience, was revived, or re-invented, in the 16th century. It owes its birth to painting, and particularly to that branch of it which was employed in the decoration of the theatre. Vitruvius informs us, that Agatharchus, inſtructed by Æſchylus, was the firſt who wrote upon this ſubject; and that afterwards the principles of this art were more diſtinctly taught by Democritus and Anaxagoras, the diſciples of Agatharchus. How they deſcribed the theory of this art we are not informed, as their writings have been loſt: however, the revival of painting in Italy was accompanied with a revival of this art; and the firſt perſon who attempted to lay down the rules of perſpective was Pietro del Borgo, an Italian. He ſuppoſed objects to be placed beyond a tranſparent tablet, and endeavoured to trace the images, which rays of light, emitted from them, would make upon it. The book, which he wrote upon this ſubject, is not now extant; and this is the more to be regretted, as it is very much commended by the famous Egnazio Dante. Upon the principles of Borgo, Albert Durer conſtructed a machine, by which he could trace the perſpective appearance of objects. Balthazar Paruſſi, having ſtudied the writings of Borgo, endeavoured to make them more intelligible. To him we owe the diſcovery of points of diſtance, to which all lines that make an angle of 45° with the ground line are drawn. Soon after, Guido Ubaldi, another Italian, found that all the lines, which are parallel to one another, and to the horizon, if they be inclined to the ground line, converge to ſome point in the horizontal line; and that through this point, alſo, a line drawn from the eye, parallel to them, will paſs. Theſe principles combined enabled him to make out a pretty complete theory of perſpective. Great improvements were made in the rules of perſpective by ſubſequent geometricians, particularly by profeſſor Graveſande, and ſtill more by Dr. Brook Taylor, whoſe principles are, in a great meaſure, new, and much more general than thoſe of any perſon before him. Although Dr. Taylor really invented his excellent method of perſpective, yet it is ſuggeſted by Mr. Robins, that the ſame method was publiſhed by Guido Ubaldi, in his "Perſpective," printed at Peſaro, in 1600. In this treatiſe, the method is delivered very clearly, and confirmed by moſt excellent demonſtrations. In the laſt book, Ubaldi applies his method to the delineation of the ſcenes of a theatre; and in this, as far as the practice is concerned, he is followed by ſignor Sabatellini, in his "Practica di fabricar Scene," of which there was a new edition at Ravenna in 1638; and to this was added a ſecond book, containing a deſcription of the machines uſed for producing the ſudden changes in the decorations of the ſtage. We are indebted to the opticians of a much later period for ingenious devices to apply the knowledge they had of optics, and eſpecially of perſpective, to the purpoſes of amuſement. See ANAMORPHOSIS.

The principles and practice of *perſpective* will be illuſtrated at large under that article.

OPTIMATES, in *Antiquity*, one of the diviſions of the Roman people, oppoſed to *populares*.

According to Tully's deſcription, the optimates were the beſt citizens, or thoſe who deſired their actions might be approved by the better ſort; and the populares thoſe, who, out of a thirſt of vain-glory, did not ſo much conſider what was right, as what would pleaſe the populace, and get an intereſt in them.

Others rather make the optimates to be the vigorous aſſertors of the dignity of the chief magiſtrate, and the ſticklers for the grandeur of the ſtate; who cared not if the inferior members ſuffered, if it were for the advancement of the commanding powers: and the populares, thoſe who courted the favour of the populace, and encouraged them to demand larger privileges, to bring matters nearer to a level.

OPTIO, among the Romans, an aſſiſtant or lieutenant belonging to every centurion.

They were called *optiones*, from *opto, I chooſe;* becauſe it was in the option of the centurion to chooſe whom he pleaſed for this employment; though at firſt it was otherwiſe, the optio being choſen by the tribune or chief commander of the legion.

The optiones were not peculiar to the camp, but were uſed alſo in many other offices of life.

OPTION, the power or faculty of wiſhing, or chooſing; or the choice a perſon makes of any thing.

When a new ſuffragan biſhop, whether created or tranſlated,

lated, is confirmed, the archbiſhop of the province, by a cuſtomary prerogative, claims the collation of the firſt vacant benefice, or dignity, in that ſee, according as he ſhall chooſe; which choice is called the archbiſhop's option.

Ever ſince archbiſhop Cranmer's time, the mode hath been to convey the advowſon, either of the firſt dignity or benefice that ſhould fall, or of ſome one certain, to the archbiſhop, his executors, or aſſigns, at firſt for 21 years, and afterwards for the next avoidance.

But in caſe the biſhop dies, or is tranſlated, before the preſent incumbent of the promotion choſen by the archbiſhop ſhall die or be removed, it is generally ſuppoſed that the option is void; inaſmuch as the granter, ſingly and by himſelf, could not convey any right or title beyond the term of his continuance in that ſee. And if the archbiſhop dies before the avoidance ſhall happen, the right of filling up the vacancy ſhall go to his executors or adminiſtrators.

OPTO-KILTEKAI, in *Geography*, a town of Chineſe Tartary. N. lat. 44° 8′. E. long. 92° 54′.

OPTOMETER, an inſtrument invented by Dr. Porterfield, and ſo named by him from its uſe in meaſuring the limits of diſtinct viſion, and in determining with great exactneſs the ſtrength and weakneſs of ſight. See his "Treatiſe on the Eye," vol. i. p. 423. The principles of its conſtruction have alſo been explained by Dr. Thomas Young, and an improved inſtrument for the ſame purpoſe has been deſcribed by him, in the Phil. Tranſ. vol. xci. part i. p. 34, &c. Let an obſtacle be interpoſed between a radiant point R (*Plate* XVII. *Optics*, *fig.* 1.) and any refracting ſurface, or lens C D, and let this obſtacle be perforated at two points, A and B, only. Let the refracted rays be intercepted by a plane, ſo as to form an image on it. Then it is evident, that when this plane, E F, paſſes through the focus of refracted rays, the image formed on it will be a ſingle point. But if the plane be advanced forwards to G H, or removed backwards to I K, the ſmall pencils, paſſing through the perforations, will no longer meet in a ſingle point, but will fall on two diſtinct ſpots of the plane, G, H, I, K; and, in either caſe, form a double image of the object. Let us now add two more radiating points, S and T (*fig.* 2.); the one nearer to the lens than the firſt point, the other more remote; and when the plane, which receives the images, paſſes through the focus of rays coming from the firſt point, the images of the ſecond and third points muſt both be double (*s s*, *t t*); ſince the plane, E F, is without the focal diſtance of rays coming from the fartheſt point, and within that of rays coming from the neareſt. Upon this principle Dr. Porterfield's optometer was founded. But if the three points be ſuppoſed to be joined by a line, and this line to be ſomewhat inclined to the axis of the lens, each point of the line, except the firſt point R (*fig.* 3.), will have a double image; and each pair of images, being contiguous to thoſe of the neighbouring radiant points, will form with them two continued lines, and the images being more widely ſeparated as the point which they repreſent is farther from the firſt radiant point, the lines, *s t*, *s t*, will converge on each ſide towards *r*, the image of this point, and there will interſect each other. The ſame happens when we look at any object through two pin-holes, within the limits of the pupil. If the object be at the point of perfect viſion, the image on the retina will be ſingle; but in every other caſe, the image being double, we ſhall appear to ſee a double object: and if we look at a line pointed nearly to the eye, it will appear as two lines, croſſing each other in the point of perfect viſion. For this purpoſe, the holes may be converted into ſlits, which render the images nearly as diſtinct, at the ſame time that they admit more light. The number may be increaſed from two to four, or more, whenever particular inveſtigations render it neceſſary.

The optometer may be made of a ſlip of card-paper, or of ivory, about eight inches in length, and one in breadth, divided longitudinally by a black line, which muſt not be too ſtrong. The end of the card muſt be cut, as is ſhewn in *fig.* 4, in order that it may be turned up, and fixed in an inclined poſition by means of the ſhoulders; or a detached piece, nearly of this form, may be applied to the optometer, as it is here engraved. A hole about half an inch ſquare muſt be made in this part; and the ſides ſo cut as to receive a ſlider of thick paper, with ſlits of different ſizes, from a 40th to a 10th of an inch in breadth, divided by ſpaces ſomewhat broader; ſo that each obſerver may chooſe that which beſt ſuits the aperture of his pupil. In order to adapt the inſtrument to the uſe of preſbyopic eyes, the other end muſt be furniſhed with a lens of four inches focal length; and a ſcale muſt be made near the line on each ſide of it, divided from one end into inches, and from the other according to the table annexed; by means of which, not only diverging, but alſo parallel and converging rays from the lens are referred to their virtual focus. The inſtrument is eaſily applicable to the purpoſe of aſcertaining the focal length of ſpectacles required for myopic or preſbyopic eyes. Our author, having been furniſhed by Mr. Cary with the numbers and focal lengths of the glaſſes commonly made, calculated the diſtances at which theſe numbers muſt be placed on the ſcale of the optometer, ſo that a preſbyopic eye may be enabled to ſee at eight inches diſtance, by uſing the glaſſes of the focal length placed oppoſite to the neareſt croſſing of the lines; and a myopic eye with parallel rays, by uſing the glaſſes indicated by the number that ſtands oppoſite their fartheſt croſſing. To facilitate the obſervations, theſe numbers are placed oppoſite that point which will be the neareſt croſſing to myopic eyes; but this, upon the arbitrary ſuppoſition of an equal capability of change of focus in every eye, which is often far from the truth. It cannot be expected, that every perſon, on the firſt trial, will fix preciſely upon that focus which beſt ſuits the defect of his ſight. Few can bring their eyes at pleaſure to the ſtate of full action, or of perfect relaxation; and a power, two or three degrees lower than that which is thus aſcertained, will be found ſufficient for ordinary purpoſes. To the ſecond table are added ſuch numbers as will point out the ſpectacles neceſſary for a preſbyopic eye, to ſee at 12 and at 18 inches reſpectively: the middle ſeries will perhaps be the moſt proper for placing the numbers on the ſcale. The optometer ſhould be applied to each eye; and, at the time of obſerving, the oppoſite eye ſhould not be ſhut, but the inſtrument ſhould be ſcreened from its view. The place of interſection may be accurately aſcertained, by means of an index ſliding along the ſcale. The optometer is repreſented in *figs.* 5 and 6; and the manner in which the lines appear in *fig.* 7.

OPUAGO, in *Geography*, a town of America, in Tioga county and ſtate of New York; 15 miles N.W. of New York.

OPULUS, in *Botany*. See VIBURNUM.

OPUNTIA. See CACTUS.

OPUS, in *Geography*, an iſland of Dalmatia, at the mouth of the Narenza. This iſland receives from the floods of the Narenza an acceſſion of ſoil, which makes a difference in height of ten feet, between the Roman times and the preſent; and yet this iſland is not every where capable of cultivation, the ſoil being marſhy, and through want of induſtry and activity undrained. Herbage of all ſorts, Indian corn, wheat and olives in particular, ſucceed wonderfully; and mulberry trees are ſo luxuriant, that the ſilk worms by feeding on them yield very fine ſilk. The vines do not ſucceed, becauſe they remain for a conſiderable part of the year under water, eſpecially in the place between the river Narenza and the Norin, oppoſite to Mercovich, a village well inhabited by healthy labourers and brave people.

OPUTO, a town of New Navarre; 210 miles S.S.E. of Caſa Grande.

OQUENDO, a town of Spain, in the province of Alava; five miles S.E. of Orduna.

OR, or ORE, a lake of Norway, in the province of Aggerhuus; 36 miles N. of Chriſtiania.

OR, in *Heraldry*, *yellow*, or the colour of gold.

Without this colour, or argent, ſilver, there can be no good armory.

In the coats of nobles, it is called *topaz*; and in thoſe of ſovereign princes, *ſol*. It is repreſented in engravings by ſmall points, or dots, all over the field, or bearing.

It is acounted the ſymbol of wiſdom, temperance, faith, force, conſtancy, &c.

*Toiſon d'*OR. See TOISON.

ORA, in *Antiquity*, was a term equivalent to an ounce; but it has been much debated among our antiquaries, whether the ora, the mention of which ſo often occurs, was a coin, or only money of account. Dr. Hickes obſerves, that the mode of reckoning money by marks and oras was never known in England till after the Daniſh ſettlements; and by examining the old nummulary eſtimates among the principal Gothic ſtates upon the Baltic, it appears that the ora and ſolidus were ſynonimous terms, and that the ora was the eighth part of the mark. From ſeveral of the Daniſh laws, it likewiſe appears that the Daniſh ora, derived by corruption from *aureus*, was the ſame as the Frank ſolidus of twelve

pence. As a weight, the ora was regarded as the uncia, or unit, by which the Daniſh mark was divided; and in Domeſday book the ora is uſed for the ounce, or the twelfth part of the nummulary Saxon pound, and the fifteenth of the commercial; as a coin, it was an aureus or the Frank ſolidus of twelve pence. And from the accidental coincidence of the Frank aureus with the eighth part of their mark, the Danes probably took occaſion to give it the new name of ora. There was another ora, mentioned in the rolls of the 27th of Henry III. the value of which was ſixteen pence; and this was probably derived from the half mancus of the Saxons. Such, in all appearance, was the original of theſe two oras; as there were no aurei of that period, to which theſe two denominations of money of ſixteen and twelve pence can poſſibly be aſcribed. It is obſerved farther, that the name ora diſtinguiſhes the gold coins in ſeveral parts of Europe to this day. The Portugueſe moidore is nothing elſe but *moeda d'oro*, from the Latin *moneta de auro*: the French *Louis d'ores* come from the ſame uſe of the word, and owe their appellation to the ora. Clarke on Coins, p. 307, &c.

Ora *Cabaça*, in *Geography*, a bay on the N. coaſt of Jamaica.

ORABY, a town of Sweden, in the province of Schonen; 32 miles S. of Chriſtianſtadt.

ORACH, or Orache, in *Botany*. See Atriplex.

Orach, *Orache*, or *Stinking Gooſe-foot*, in *Botany* and the *Materia Medica*. See Chenopodium *Olidum*.

Orach, *Berry-Bearing*. See Blitum.

Orach, *Creeping ſhrubby*. See Atraphaxis.

Orach, *Wild*. See Chenopodium.

Orach, in *Geography*, a town of Boſnia, the capital of a Sangiacate; 96 miles S.S.W. of Belgrade.

ORACHAU, a lake of Sileſia, in the principality of Glogau; five miles N.N.E. of Kontop.

ORACLE, an anſwer, uſually couched in very dark and ambiguous terms, ſuppoſed to be given by dæmons of old, either by the mouths of their idols, or by thoſe of their prieſts, to the people, who conſulted them on things to come.

Oracle is alſo uſed for the dæmon who gave the anſwer, and the place where it was given. See Dæmon.

Seneca defines oracles to be enunciations by the mouths of men of the will of the gods: and Cicero ſimply calls them the language of the gods, "Deorum oratio." Among the Pagans they were held in high eſtimation; and they were conſulted on a variety of occaſions, pertaining to national enterpriſes and private life. When they made peace or war, enacted laws, reformed ſtates, or changed the conſtitution, they had in all theſe caſes recourſe to the oracle by public authority. Alſo, in private life, if a man wiſhed to marry, if he propoſed to take a journey, or to engage in any buſineſs of importance, he repaired to the oracle for counſel. Mankind have had always a propenſity to explore futurity; and conceiving that future events were known to their gods, who poſſeſſed the gift of prophecy, they ſought information and advice from the oracles, which in their opinion were ſupernatural and divine communications. The inſtitution of oracles ſeemed to gratify the prevalent curioſity of mankind, and proved a ſource of immenſe wealth, as well as authority and influence, to thoſe who had the command of them. Accordingly every nation, in which idolatry has ſubſiſted, had its oracles, by means of which impoſture practiſed on ſuperſtition and credulity.

The principal oracles of antiquity are that of Abæ, mentioned by Herodotus; that of Amphiaraus at Oropus in Macedonia; that of the Branchidæ at Didymus; that of the camps at Lacedæmon; that of Dodona; that of Jupiter Ammon; that of Nabarca, in the country of the Anariaci, near the Caſpian ſea; that of Trophonius, mentioned by Herodotus; that of Chryſopolis; that of Claros, in Ionia; that of Amphilochus at Mallus; that of Patarea; that of Pello in Macedonia; that of Phaſelides in Cilicia; that of Sinope in Paphlagonia: that of Orpheus's head at Leſbos, mentioned by Philoſtratus, in the life of Apollonius, &c.

But of all oracles, the oracle of Apollo Pythius at Delphi was the moſt celebrated; this was conſulted in the *dernier reſſort*, by moſt of the princes of thoſe ages. See Delphi and Pythia.

We have already obſerved that moſt of the Pagan deities had their appropriate oracles. Apollo had the greateſt number: ſuch as thoſe of Claros, of the Branchidæ, of the ſuburbs of Daphne at Antioch, of Delos, of Argos, of Troas, Æolis, &c. of Baiæ in Italy, and others in Cilicia, in Egypt, in the Alps, in Thrace, at Corinth, in Arcadia, in Laconia, and in many other places enumerated by Van Dale. Jupiter, beſides that of Dodona and ſome others, the honour of which he ſhared with Apollo, had one in Bœotia, under the name of Jupiter the Thunderer, and another in Elis, one at Thebes and at Meroe, one near Antioch, and ſeveral others. Æſculapius was conſulted in Cilicia, at Apollonia, in the iſle of Cos, at Epidaurus, Pergamus, Rome, and elſewhere: Mercury had oracles at Patras, upon Hæmon, and in other places: Mars in Thrace, Egypt, and elſewhere: Hercules at Cadiz, Athens, in Egypt, at Tivoli, in Meſopotamia, where he iſſued his oracles by dreams, whence he was called "Somnialis:" Iſis, Oſiris, and Serapis delivered in like manner their oracles by dreams, as we learn from Pauſanias, Tacitus, Arrian, and other writers: that of Amphilochus was alſo delivered by dreams: the ox Apis had alſo his oracle in Egypt. The gods, called Cabiri, had their oracle in Bœotia: Diana, the ſiſter of Apollo, had ſeveral oracles in Egypt, Cilicia, Epheſus, &c. Thoſe of Fortune at Prænеſte and of the Lots at Antium are well known. The Fountains alſo delivered oracles, for to each of them a divinity was aſcribed: ſuch was the fountain of Caſtalia at Delphi, another of the ſame name in the ſuburbs of Antioch, and the prophetic fountain near the temple of Ceres in Achaia. Juno had ſeveral oracles; one near Corinth, one at Nyſa, and others at other places. Latona had one at Butis in Egypt: Leucothea had one in Colchis: Memnon in Egypt; Machaon at Gerania in Laconia; Minerva had one in Egypt, in Spain, upon mount Ætna, at Mycenæ and Colchis, and in other places. Thoſe of Neptune were at Delphos, at Calauria, near Neoceſarea, and elſewhere. The Nymphs had theirs in the cave of Corycia. Pan had ſeveral, the moſt famous of which was that in Arcadia. That of the Palici was in Sicily. Pluto had one at Nyſa. Saturn had oracles in ſeveral places, but the moſt famous were thoſe of Cumæ in Italy and of Alexandria in Egypt. Thoſe of Venus were diſperſed in ſeveral places, at Gaza, upon mount Libanus, at Paphos, in Cyprus, &c. Serapis had one at Alexandria, conſulted by Veſpaſian. Venus Aphacite had one at Aphaca between Heliopolis and Byblus. Geryon, the three-headed monſter, ſlain by Hercules, had an oracle in Italy near Padua, conſulted by Tiberius; that of Hercules was at Tivoli, and was given by lots, like thoſe at Prænеſte and Antium. The demi-gods and heroes had likewiſe their oracles, ſuch were thoſe of Caſtor and Pollux at Lacedæmon, of Amphiaraus, of Mopſus in Cilicia, of Ulyſſes, Amphilochus, Sarpedon in Troas, Hermione in Macedonia, Paſiphae in Laconia, Chalcas in Italy, Ariſtæus in Bœotia, Autolycus at Sinope, Phryxus among the Colchi, Zamolxis among the Getæ, Epheſtion

the minion of Alexander, and Antinous, &c. &c. for which we refer to Van Dale. The reſponſes of oracles were delivered in a variety of ways: at Delphi, they interpreted and put into verſe what the prieſteſs pronounced in the time of her fury.

Mr. Bayle obſerves, that at firſt it gave its anſwers in verſe; and that it fell at length to proſe, upon the people's beginning to laugh at the poorneſs of its verſification. The Epicureans made this the ſubject of their jeſts, and ſaid, in raillery, it was ſurprizing enough, that Apollo, the god of poetry, ſhould be a much worſe poet than Homer, whom he himſelf had inſpired. By the railleries of theſe philoſophers, and particularly thoſe of the Cynics and Peripatetics, the prieſts were at length obliged to deſiſt from the practice of verſifying the reſponſes of the Pythia, which, according to Plutarch, was one of the principal cauſes of the declenſion of the oracle of Delphos.

At the oracle of Ammon, the prieſts pronounced the reſponſe of their god; at Dodona, the reſponſe was iſſued from the hollow of an oak; at the cave of Trophonius, the oracle was inferred from what the ſuppliant ſaid before he recovered his ſenſes; at Memphis, they drew a good or bad omen, according as the ox Apis received or rejected what was preſented to him, which was alſo the caſe with the fiſhes of the fountain of Limyra. The ſuppliants, who conſulted the oracles, were not allowed to enter the ſanctuaries where they were given; and accordingly care was taken, that neither the Epicureans nor Chriſtians ſhould come near them. In ſeveral places, the oracles were given by letters ſealed up, as in that of Mopſus, and at Mallus in Cilicia. Oracles were frequently given by lot, the mode of doing which was as follows: the lots were a kind of dice, on which were engraven certain characters or words, whoſe explanations they were to ſeek on tables made for the purpoſe. The way of uſing theſe dice for knowing futurity, was different, according to the places where they were uſed. In ſome temples, the perſon threw them himſelf; in others, they were dropped from a box; whence came the proverbial expreſſion, "the lot is fallen." This playing with dice was always preceded by ſacrifices and other cuſtomary ceremonies. (See SORTES, &c.) The ambiguity of the oracles in their reſponſes, and their double meaning, contributed to their ſupport.

Ablancourt obſerves, that the ſtudy or reſearch of the meaning of oracles was but a fruitleſs thing; and that they were never underſtood till after their accompliſhment. Hiſtorians relate, that Crœſus was tricked by the ambiguity and equivocation of the oracle:

Κροισος Αλυν διαβας μεγαλην αρχην καταλυσει.

Thus rendered in Latin:

"Crœſus Halym ſuperans magnam pervertet opum vim."

Thus, if the Lydian monarch had conquered Cyrus, he overthrew the Aſſyrian empire; if he himſelf was routed, he overturned his own. That delivered to Pyrrhus, which is compriſed in this Latin verſe,

"Credo equidem Æacidas Romanos vincere poſſe,"

had the ſame advantage; for, according to the rules of ſyntax, either of the two accuſatives may be governed by the verb, and the verſe be explained, either by ſaying the Romans ſhall conquer the Æacidæ, of whom Pyrrhus was deſcended, or thoſe ſhall conquer the Romans. When Alexander fell ſick at Babylon, ſome of his courtiers, who happened to be in Egypt, or who went thither on purpoſe, paſſed the night in the temple of Serapis, to enquire if it would not be proper to bring Alexander to be cured by him. The god anſwered, it was better that Alexander ſhould remain where he was. This in all events was a very prudent and ſafe anſwer. If the king recovered his health, what glory muſt Serapis have gained by ſaving him the fatigue of the journey! If he died, it was but ſaying he died in a favourable juncture after ſo many conqueſts; which, had he lived, he could neither have enlarged nor preſerved. That is actually the conſtruction they put upon the reſponſe; whereas had Alexander undertaken the journey, and died in the temple, or by the way, nothing could have been ſaid in favour of Serapis.

When Trajan had formed the deſign of his expedition againſt the Parthians, he was adviſed to conſult the oracle of Heliopolis, to which he had no more to do but ſend a note under a ſeal. That prince, who had no great faith in oracles, ſent thither a blank note; and they returned him another of the ſame. By this Trajan was convinced of the divinity of the oracle. He ſends back a ſecond note to the god, wherein he enquired, whether he ſhould return to Rome after finiſhing the war he had in view. The god, as Macrobius tells the ſtory, ordered a vine, which was among the offerings of his temple, to be divided into pieces, and brought to Trajan. The event juſtified the oracle; for the emperor dying in that war, his bones were carried to Rome, which had been repreſented by that broken vine. As the prieſts of that oracle knew Trajan's deſign, which was no ſecret, they happily deviſed that reſponſe, which, in all events, was capable of a favourable interpretation, whether he routed and cut the Parthians in pieces, or if his army met with the ſame fate.

Sometimes the reſponſes of the oracles were mere banter, as in the caſe of the man who wiſhed to know by what means he might become rich, and who received for anſwer from the god, that he had only to make himſelf maſter of all that lay between Sicyon and Corinth. Another wanting a cure for the gout, was anſwered by the oracle, that he was to drink nothing but cold water.

There are two points in diſpute on the ſubject of oracles; *viz.* whether they were human, or diabolical machines; and whether or not they ceaſed upon the publication or preaching of the goſpel.

Moſt of the fathers of the church ſuppoſed that the devil iſſued oracles; and looked on it as a pleaſure he took to give dubious and equivocal anſwers, in order to have a handle to laugh at them. Voſſius allows that it was the devil who ſpoke in oracles; but thinks that the obſcurity of his anſwers was owing to his ignorance as to the preciſe circumſtances of events. "That artful and ſtudied obſcurity, in which the anſwers were couched, ſays he, ſhewed the embarraſs the devil was under; as thoſe double meanings they uſually bore provided for their accompliſhment. Where the thing foretold did not happen accordingly, the oracle, forſooth, was miſunderſtood.

Euſebius has preſerved ſome fragments of a philoſopher, called Oenomaus; who, out of reſentment for his having been ſo often fooled by the oracles, wrote an ample confutation of all their impertinencies: "When we come to conſult thee," ſays he to Apollo, "if thou ſeeſt what is in futurity, why doſt thou uſe expreſſions that will not be underſtood? Doſt thou not know, that they will not be underſtood? If thou doſt, thou takeſt pleaſure in abuſing us; if thou doſt not, be informed of us, and learn to ſpeak more clearly. I tell thee, that if thou intendeſt an equivoque, the Greek word whereby thou affirmedſt, that Crœſus ſhould overthrow a great empire, was ill choſen; and that it could ſignify nothing but Crœſus's conquering

Cyrus. If things muſt neceſſarily come to paſs, why doſt thou amuſe us with thy ambiguities? What doſt thou, wretch as thou art, at Delphi; employed in muttering idle prophecies!"

But Oenomaus is ſtill more out of humour with the oracle, for the anſwer which Apollo gave the Athenians, when Xerxes was about to attack Greece with all the ſtrength of Aſia. The Pythian declared, that Minerva, the protectreſs of Athens, had endeavoured in vain to appeaſe the wrath of Jupiter; yet that Jupiter, in complaiſance to his daughter, was willing the Athenians ſhould ſave themſelves within wooden walls; and that Salamis ſhould behold the loſs of a great many children, dear to their mothers, either when Ceres was ſpread abroad, or gathered together.

Here Oenomaus loſes all patience with the god of Delphi. "This conteſt," ſays he, "between father and daughter is very becoming the deities! It is excellent, that there ſhould be contrary inclinations and intereſts in heaven. Poor wizard, thou art ignorant whoſe the children are, that Salamis ſhall ſee periſh; whether Greeks or Perſians. It is certain they muſt be either one, or the other; but thou needeſt not to have told ſo openly, that thou kneweſt not which. Thou concealeſt the time of the battle under thoſe fine poetical expreſſions, *either when Ceres is ſpread abroad, or gathered together;* and wouldeſt thou cajole us with ſuch pompous language? Who knows not, that if there be a ſea-fight, it muſt either be in ſeed-time or harveſt? It is certain it cannot be in winter. Let things go how they will, thou wilt ſecure thyſelf by this Jupiter, whom Minerva is endeavouring to appeaſe. If the Greeks loſe the battle, Jupiter proved inexorable to the laſt; if they gain it, why then Minerva at length prevailed."

It is a very general opinion among the more learned, that oracles were all mere cheats and impoſtures; either calculated to ſerve the avaricious ends of the heathen prieſts, or the political views of the princes.

M. Bayle ſays poſitively, they were mere human artifices, in which the devil had no hand. He was ſtrongly ſupported by Van Dale, and M. Fontenelle, who have written expreſsly on the ſubject.

Father Balthus, a Jeſuit, wrote a treatiſe in defence of the fathers with regard to the origin of oracles; but without denying the impoſture of the prieſts, often blended with the oracles. He maintains the intervention of the devil in ſome predictions, which could not be aſcribed to the cheats of Jeſuits alone. The abbé Banier eſpouſes the ſame ſide of the queſtion, and objects that oracles would not have laſted ſo long, and ſupported themſelves with ſo much ſplendour and reputation, if they had been merely owing to the forgery of the prieſts.

Biſhop Sherlock, in his "Diſcourſes concerning the Uſe and Intent of Prophecy," expreſſes his opinion, that it is impious to diſbelieve the Heathen oracles, and to deny them to have been given out by the devil; to which aſſertion Dr. Middleton, in his "Examination, &c." (Works, vol. iii. p. 186.) replies, that he is guilty of this impiety, and that he thinks himſelf warranted to pronounce from the authority of the beſt and wiſeſt of the Heathens themſelves, and the evidence of plain facts, which are recorded of thoſe oracles, as well as from the nature of the thing itſelf, that they were all mere impoſture, wholly invented and ſupported by human craft; without any ſupernatural aid or interpoſition whatſoever. He alleges, that Cicero, ſpeaking of the Delphic oracle, the moſt revered of any in the Heathen world, declares, "that nothing was become more contemptible, not only in his days, but long before him;" that Demoſthenes, who lived about 300 years earlier, affirmed of the ſame oracle, in a public ſpeech to the people of Athens, that it "was gained to the intereſts of king Philip," an enemy to that city; that the Greek hiſtorians tell us, how, on ſeveral other occaſions, it had been corrupted by money, to ſerve the views of particular perſons and parties, and the propheteſs ſometimes depoſed for bribery, and for lewdneſs; that there were ſome great ſects of philoſophers, who, by principle, diſavowed the authority of all oracles; agreeably to all which Strabo tells us, that divination in general and oracles had been in high credit among the ancients, but in his days were treated with much contempt; laſtly, that Euſebius alſo, the great hiſtorian of the primitive church, declares, that there were "600 writers among the Heathens themſelves," who had publicly written againſt the reality of them. Although the primitive fathers conſtantly affirmed them to have been the real effects of a ſupernatural power, and given out by the devil; yet M. de Fontenelle maintains, that, while thoſe fathers preferred that way of combating the authority of the oracles, as the moſt commodious to themſelves, and to the ſtate of the controverſy, between them and the Heathens, yet they believed them at the ſame time to be nothing elſe but the effects of human fraud and contrivance; which he has illuſtrated by the examples of Clemens of Alexandria, Origen, and Euſebius.

Plutarch has a treatiſe on the ceaſing of ſome oracles; and Van Dale, a Dutch phyſician, has a volume to prove they did not ceaſe at the coming of Chriſt; but that many of them ceaſed long before; and that others held till the fall of Paganiſm, under the empire of Theodoſius the Great; when Paganiſm being diſſipated, theſe inſtitutions could no longer ſubſiſt.

Van Dale was anſwered by a German, one Mœbius, profeſſor of theology at Leipſic, in 1685. M. Fontenelle eſpouſed Van Dale's ſyſtem, and improved upon it in his Hiſtory of Oracles; and ſhewed the weakneſs of the argument uſed by many writers in behalf of Chriſtianity, drawn from the ceaſing of oracles.

It was Euſebius who firſt endeavoured to perſuade the Chriſtians, that the coming of Jeſus Chriſt had ſtruck the oracles dumb; though it appears from the laws of Theodoſius, Gratian, and Valentinian, that the oracles were ſtill conſulted as low as the year 358. Cicero ſays, the oracles became dumb, in proportion as people, growing leſs credulous, began to ſuſpect them for cheats.

Plutarch alleges two reaſons for the ceaſing of oracles: the one was Apollo's chagrin; who, it ſeems, took it in dudgeon to be interrogated about ſo many trifles. The other was, that in proportion as the genii, or dæmons, who had the management of the oracles, died, and became extinct, the oracles muſt neceſſarily ceaſe. He adds a third and more natural cauſe for the ceaſing of oracles; *viz.* the forlorn ſtate of Greece, ruined and deſolated by wars. For, hence, the ſmallneſs of the gains let the prieſts ſink into a poverty and contempt too bare to cover the fraud.

That the oracles were ſilenced about or ſoon after the time of our Saviour's advent, may be proved, ſays Dr. Leland, in the firſt volume of his learned work on "The Neceſſity and Advantage of Revelation, &c." from expreſs teſtimonies, not only of Chriſtian, but of Heathen authors. Lucan, who wrote his "Pharſalia" in the reign of Nero, ſcarcely 30 years after our Lord's crucifixion, laments it as one of the greateſt misfortunes of that age, that the Delphian oracle, which he repreſents as one of the choiceſt gifts of the gods, was become ſilent.

"————————Non ullo ſæcula dono
Noſtra carent majore Deûm, quam Delphica Sedes
Quod ſileat." Pharſal. l. v. v. 111.

In

In like manner Juvenal ſays,

" ——————Delphis oracula ceſſant,
Et genus humanum damnat caligo futuri."
Sat. vi. v. 544.

Lucian ſays, that when he was at Delphi, the oracle gave no anſwer, nor was the prieſteſs inſpired. See his Phalaris. Oper. tom. i. This likewiſe appears from Plutarch's treatiſe, why the oracles ceaſe to give anſwers, already cited; whence it is alſo manifeſt, that the moſt learned Heathens were very much at a loſs how to give a tolerable account of it. Porphyry, in a paſſage uſed from him by Euſebius (Præp. Evang. lib. v. c. 1.) ſays, "the city of Rome was overrun with ſickneſs. Æſculapius and the reſt of the gods having withdrawn their converſe with men; becauſe ſince Jeſus began to be worſhipped, no man had received any public help or benefit from the gods."

ORACLES *of the Sibyls*. See SIBYL.

ORAHOVITZKA, in *Geography*, a town of Sclavonia; 16 miles W. of Valpo.

ORAISON, a town of France, in the department of the Lower Alps, on the Durance; 18 miles S.W. of Digne.

ORAL, ſomething delivered by the mouth, or voice. In this ſenſe, we ſay, *oral law*, *oral tradition*, &c.

ORAMANE, in *Geography*, a river of Canada, which runs into the gulf of St. Lawrence, N. lat. 50° 7'. W. long. 61°.

ORAMTCHI-HOTUN, a town of Thibet; 58 miles W.N.W. of Tourfan. N. lat. 44° 2'. E. long. 88° 17'.

ORAN, or WEIRAN, a town of Algiers, and one of the largeſt in the province of Maſcara, ſometimes called Tremecen or Tlemſan, ſituated on the declivity and near the foot of a high mountain, which overlooks it from the N. and N.W. Towards the ſea the city riſes in the form of an amphitheatre, and is ſurrounded with forts and batteries. Cloſe to it lies a ſtrong caſtle, called "Alcazava," in which the Spaniſh governor reſides. It has ſtrong and regular fortifications, and can eaſily be ſupplied by the Spaniards with proviſions and warlike ſtores. On the higheſt hill ſtands Fort St. Croix, whoſe guns command the city and the adjacent country. From this fort they make ſignals of the approach of ſhips, and carefully watch the motions of the Moors, who often attempt predatory excurſions into the neighbouring diſtricts. A deep winding valley ſerves as a trench on the S. ſide, where, likewiſe, at a little diſtance, is a very plentiful ſpring of excellent water. The rivulet formed by this fountain conforms in its courſe to the ſeveral windings of the valley, and paſſing afterwards under the walls of the city, liberally ſupplies it with water. In 1509 this city was taken by the Spaniards, under the command of cardinal Ximenes, then prime miniſter, and continued in their poſſeſſion till the diſturbances occaſioned in Spain by the ſucceeding war in 1708, when the Algerines retook it. But notwithſtanding all their expence and labour for its preſervation, it was recovered by the Spaniards in 1732, and ever ſince they have maintained the uninterrupted poſſeſſion of it, and have adorned it with ſeveral beautiful churches and other edifices. Dr. Shaw found no Roman antiquities in Oran. The Spaniards, however, in their architecture have imitated the Roman ſtyle, and they have carved upon the friezes, and in other convenient places, ſeveral inſcriptions in large characters, and in their own language. In the year 1790 this place was almoſt deſtroyed by an earthquake; the number of perſons who periſhed was eſtimated at more than 2000, including 22 officers, and 304 private ſoldiers belonging to the garriſon. It has a pariſh church, three monaſteries, and a hoſpital; and the number of inhabitants, according to the account given of it by the Spaniards, amounts to 12,000. A conſiderable number of Mahometans take refuge in Oran; they occupy a diſtinct part of the city, receive pay from the court of Spain, and render ſignal ſervices againſt the Moors. The greateſt part of the inhabitants of Oran conſiſts of ſuch as have been baniſhed from Spain; and the ſame may be alſo ſaid, in a great meaſure, of the ſoldiers who compoſe the garriſon. Five regiments are commonly ſtationed here; but on account of continual deſertion, their ſtrength ſcarcely equals that of four complete regiments. One of them wholly conſiſts of malefactors, who have been condemned to remain here for life. The reſt are ſuch as have been tranſported for one or more years. Here is likewiſe a military ſchool. Around the city are pleaſant gardens; but it is very dangerous to cultivate them, on account of the Moors and Arabs, who frequently lie in ambuſh among them. The ſame objection lies againſt the cultivation of the fields in the vicinity; ſo that the garriſon and the inhabitants muſt be ſupplied with proviſions immediately from Spain. N. lat. 35° 35'. W. long. 0° 35'.

ORANAI. See RANAI.

ORANDO *pro Rege & Regno*, an ancient writ. Before the Reformation, while there was no ſtanding collect for a ſitting parliament, when the houſes of parliament were met, they petitioned the king that he would require the biſhops and clergy to pray for the peace and good government of the realm, and for a continuance of the good underſtanding between his majeſty and the eſtates of the kingdom; and accordingly the writ *de orando pro rege & regno* was iſſued, which was common in the time of king Edward III.

ORANG's KEY, in *Geography*, one of the Bahama iſlands. N. lat. 24° 29'. W. long. 79° 35'.

ORANGABAD, a town of Hindooſtan, in the ſubah of Agra; 15 miles N. of Fattipour.

ORANGE-TREE, *Aurantium*, in *Botany*, *Gardening*, and the *Materia Medica*. See CITRUS.

Oranges are ordinarily preſerved in halves and quarters. They are firſt peeled, then ſcooped, and dried in a ſtove. Orangeal is the orange-peel cut in pieces, and candied. Italy furniſhes a great deal of flower of oranges, either dry or liquid.

ORANGE, *Sea*, in *Natural Hiſtory*, a name given by count Marſigli to a very remarkable ſpecies of marine ſubſtance, which he calls a plant. This is the ALCYONIUM *Lyncurium* of the Linnæan ſyſtem; which ſee. It is tough and firm in its ſtructure, and in many things reſembles the common fucus; but inſtead of growing into the branched form the generality of thoſe ſubſtances have, it is round and hollow, and in all reſpects reſembles the ſhape of an orange. It has, by way of root, certain very fine filaments, which faſten themſelves to the rocks, or to ſhells, ſtone, or any thing elſe that comes in the way. From theſe there grows no pedicle, but the body of the orange, as it is called, is faſtened by them to the rock, or other ſolid ſubſtances. The orange itſelf is uſually of about three or four inches in diameter; and while in the ſea, is full of water, and retains this when taken up. In this ſtate it frequently weighs a pound and a half, but when the water is let out, and it is dried, it becomes a mere membrane, weighing ſcarcely any thing. It is beſt preſerved, by ſtuffing it full of cotton, as ſoon as the water is let out of it, and hanging it up to dry in this form. Its ſurface is irregular and rough, and its colour a duſky green on the outſide, and a clearer, but ſomewhat blueiſh-green within; and its thickneſs about an eighth part of an inch. When viewed by the microſcope, it is ſeen to be all over covered with ſmall glandules, or, indeed, compoſed of them;

them; for they ſtand ſo thick, one by another, as to leave no ſpace between, and ſeem to make up the whole ſubſtance; ſo that it appears very like the rough ſhagreen ſkin uſed to cover toys. Theſe are all ſo many hollow ducts, through which the ſea-water finds a paſſage into the globe formed by this ſkin, and by this means it is kept always full and diſtended; on cutting it with a pair of ſciſſars, the water immediately runs out, and the ſkins collapſe; but there is ſomething farther remarkable, which is, that the whole ſubſtance, near the wounded place, is in motion, and ſeems as if alive, and ſenſible of the wound. The glandules are found full of water, and reſembling ſmall tranſparent bottles; and what goes to the ſtructure of the ſubſtance beſide theſe, is an aſſemblage of a vaſt number of filaments, all which are alſo hollow, and filled with a clear and tranſparent fluid.

There is another ſubſtance of this kind, deſcribed by count Marſigli, Triumfetti, and others, and called the *ramoſe*, or branched orange. This is very much of the nature of the former; but, inſtead of conſiſting of one round globule, it is formed of ſeveral oblong ones, all joined ſo together, that they repreſent the branches of ſome of the fucuſes, but that they are ſhorter; and theſe are all hollow and full of water, in the ſame manner as the ſingle globes of the common kind. This has, by way of root, certain fine and ſlender filaments, which faſten it to the ſtones or ſhells near which it is produced: and it is of a duſky greeniſh colour on the ſurface, and of a fine blueiſh-green within. The ſurface, viewed by the microſcope, appears rough, as in the other, and the glandules are of the ſame kind, and are always found full of clear water. Marſigli, Hiſt. de la Mer, p. 81. See CORALLINES.

ORANGE-*Colour*, is a hue or die that partakes equally of red and yellow; or is a medium between the two.

In heraldry, the term *orange* or *orenge* is given in blazon to all roundles that are tenne or tawny.

ORANGE-*Dew*, a ſort of dew which falls in the ſpring-time from the leaves of orange and lemon-trees, and is extremely fine and ſubtile. M. De La Hire obſerving this, placed ſome flat pieces of glaſs under the leaves to receive it, and having thus procured ſome large drops of it, was deſirous of finding out what it was. He ſoon found that it was not a merely aqueous fluid, becauſe it did not evaporate in the air; and that it was not a reſin, becauſe it readily and perfectly mixed with water: it was natural here to ſuppoſe it a liquid gum; but neither did this, on examination, prove to be the caſe; for being laid on paper, it did not dry as the other liquid gums do. Its anſwering to none of theſe characters, and its being of the conſiſtence of honey, and of a ſweet ſugar-like taſte, gave a ſuſpicion of its being a kind of manna; and whatever in the other trials had proved it not a reſin, a gum, &c. all equally tends to prove that it is this ſubſtance.

ORANGE-*flower-Water*. See WATER.

ORANGE-*Lake*. See LAKE.

ORANGE, *Mock*. See PHILADELPHUS.

ORANGE, in *Geography*, a bay on the N.E. coaſt of Jamaica; and alſo a bay at the N.W. end of the ſame iſland, in which is a ſmall iſland, called "Orange-key, or Cay."—Alſo, a bay on the E. coaſt of Newfoundland. N. lat. 50° 32′. W. long. 56° 10′.—Alſo, a cape, the E. point of Oyapok river, S.E. of Cayenne iſland. N. lat. 4° 20′. W. long. 50° 50′.

ORANGE, a county of Vermont in America, containing 20 townſhips and 18,238 inhabitants. The county-town is Newbury, and the townſhips S. of it are Bradford, Fairlee, and Thetford. The land is high and furniſhes numerous ſtreams in oppoſite directions, both to Connecticut river and to lake Champlain.—Alſo, a townſhip on the N. line of the above county, in the N.E. corner of which is Knox's mountain, containing 338 inhabitants.—Alſo, a townſhip, formerly "Cardigan," in Grafton county, New Hampſhire, which gives riſe to an E. branch of Maſcomy river; incorporated in 1789 and containing 203 inhabitants; 20 miles E. of Dartmouth college.—Alſo, a townſhip of Maſſachuſetts, on the E. line of Hampſhire county, on Miller's river, 75 miles N.W. by W. of Boſton; incorporated in 1783, and containing 766 inhabitants.—Alſo, a mountainous and hilly county of New York, divided into 9 townſhips, the chief of which is Goſhen; containing 29,355 inhabitants, of whom 1145 are ſlaves. The excellent butter of this county is collected at Newburgh and New Windſor, and thence tranſported to New York. On the N. ſide of the mountains in this county is a very valuable tract called the "Drowned Lands," and containing about 40 or 50,000 acres.—Alſo, a town called "Orangedale," in Eſſex county, New Jerſey, containing about 80 houſes, a Preſbyterian church, and a flouriſhing academy, and lying N.W. of Newark, which adjoins to it.—Alſo, a county of Hillſborough diſtrict, North Carolina; containing 15,657 inhabitants, of whom 3327 are ſlaves. The chief town is Hillſborough.—Alſo, a county of South Carolina, in Orangeburg diſtrict.—Alſo, a county of Virginia, containing 6207 free inhabitants, and 5242 ſlaves: this county is 55 miles long and 10 broad, and comprehends 320,000 acres. It has been ſo long under culture with tobacco and Indian corn, that the ſoil is greatly impoveriſhed. It has three epiſcopal churches, five or ſix Baptiſt churches, and one belonging to the Preſbyterians; 127 miles from Waſhington.—Alſo, a town of France, and principal place of a diſtrict, in the department of Vaucluſe; before the revolution the capital of a principality and the ſee of a biſhop. The town contains 7270, and its two cantons 18,493 inhabitants, on a territory of 287½ kiliometres, in 10 communes. Among other remains of Roman antiquities in this place are a fine triumphal arch, and an amphitheatre. The principality extends about 10 miles in length and 7 in breadth; and the annual revenue was about 50,000 livres. In the 11th century it had courts of its own, and ſoon acquired the title of a principality. The ſovereignty was in the year 1598 conferred to the houſe of Naſſau by the treaty of Vervins, in 1678 by that of Nimeguen, and in 1697 by that of Ryſwick. William Henry, prince of Orange, was ſtadtholder of Holland in 1672, and in 1689 king of England. After his death, the moſt powerful of the kings who laid claim to it was the king of Pruſſia; but in 1712, king Frederick William, by the treaty of Utrecht, ceded it to the houſe of Bourbon. At the cloſe of the year 1714, it was annexed to the government of Dauphiny, the generality and intendancy of Grenoble and Montelimart. In 1722, Louis XV. gave it to the prince of Conti. It contained one city, two ſmall towns, and about nine villages, and was exempted from all the uſual taxes in France. N. lat. 44° 8′. E. long. 4° 53′.

ORANGE *River*, a river of Jamaica, which runs into the ſea, 4 miles E. of Montego bay.—Alſo, a river of Africa, which riſes in a mountain in the eaſtern part of the ſettlement of the Cape of Good Hope, about 150 miles from the Indian ſea, and after a weſterly courſe of about 600 miles runs into the Atlantic, S. lat 28° 30′.

ORANGE-*Town*, or *Greenland*, a plantation in Cumberland county, and ſtate of Maine in America, N.W. of Waterford. This is a mountainous country; ſome of its mountains having precipices 200 feet perpendicular. The ſides

of

of the mountains and the vallies are fertile, producing good crops, and, in ſome inſtances, affording wild onions, which reſemble thoſe that are cultivated. Winter rye, which is the chief produce, has amounted to twenty buſhels on an acre. The neighbouring country formerly abounded with variety of game, ſuch as mooſe deer, bears, beavers, racoons, ſables, &c. but ſince it has been inhabited game is become ſcarce.

ORANGE-*Town*, or *Tappan*, a townſhip in Orange county, New York, ſituated on the W. ſide of the Tappan ſea, oppoſite to Philipſburg, and about 27 miles N. of New York city. This townſhip is bounded E. by Hudſon river, and S. by the ſtate of New Jerſey. It contained, in 1790, 1175 free inhabitants, and 203 ſlaves.

ORANGE-*Town*, a town of Waſhington county, in the ſtate of Maine; 19 miles from Machias.

ORANGEADE, a drink made of orange-juice, water, and ſugar.

Lemery ſays it may be given to people in the height of a fever.

ORANGEBURG, in *Geography*, a diſtrict of South Carolina, bounded S.W. by Ediſto river: it is divided into three counties, *viz.* Lewiſburg, Orange, and Lexington. In its interior are extenſive foreſts of pine. It is watered by the N. and S. branches of Ediſto river, and contains 13,766 inhabitants, of whom 5356 are ſlaves.—Alſo, a poſt-town of South Carolina, and capital of the above diſtrict, on the E. ſide of the N. branch of Ediſto river: containing a court-houſe, gaol, and about 20 houſes; 77 miles N.N.W. of Charleſton.

ORANGERY, a gallery in a garden, or parterre, expoſed to the ſouth, but well cloſed with a glaſs window, to preſerve oranges in during the winter ſeaſon.

The orangery of Verſailles is the moſt magnificent that ever was built: it has wings, and is decorated with a Tuſcan order.

ORANGERY is alſo uſed for the parterre, where the oranges are expoſed in kindly weather.

ORANG-OUTANG, in *Zoology*, the *Homo ſylveſtris* of Edwards, *Simia ſatyrus* of Linnæus. (See SIMIA. See alſo MAN.) Theſe animals will attack and kill the negroes who wander in the woods; drive away the elephants, beating them with their fiſts or with clubs; and throw ſtones at people who offend them; they ſleep in trees, and ſhelter themſelves from the inclemency of the weather; their appearance is grave, and their diſpoſition melancholy; they are very ſwift, walk erect, and can only be taken alive, and tamed when they are young; in which caſe they are very docile. M. Buffon relates, that he had ſeen this animal offer his hand to thoſe who came to ſee him, and walk with them, as if he had been one of the company; that he has ſeen him ſit at table, unfold his napkin, wipe his lips, make uſe of his knife and fork, pour out his drink into a glaſs, take his cup and ſaucer, put in ſugar, pour out the tea, and ſtir it, in order to let it cool; and that he has done this not only at the command of his maſter, but often without bidding. He did no kind of miſchief, and offered himſelf to be careſſed by ſtrangers. The food which he preferred to every other was dried ripe fruit. A traveller relates, that he has ſeen a female of this ſpecies at Java, who every morning regularly made its own bed; at night lay down with the head on the bolſter, and covered itſelf with the quilt. When its head ached, it wrapped a handkerchief round it. Hoppius, in his Anthropomorpha, 1760, takes great pains to prove, that the orang-outang is incapable, from the extreme dilatation of the pupil, of ſeeing in the day time. Dr. Camper, late profeſſor of aſtronomy, &c. in the univerſity of Groningen, having diſſected the whole organ of voice in the orang, in apes, and ſeveral monkies, concludes, that orangs and apes are not made to modulate the voice like men; for the air paſſing by the *rima glottidis* is immediately loſt in the ventricles or ventricle of the neck, as in apes and monkies, and muſt, conſequently, return from thence without any force and melody within the throat and mouth of theſe creatures; and this ſeems to be the moſt evident proof of the incapacity of orangs, apes, and monkies, to utter any modulated voice, as indeed they have never been obſerved to do. Phil. Tranſ. vol. lxix. part i. art. 14. where the reader may find an account of the diſſection of the organs of ſpeech of the orang-outang, illuſtrated by figures. See *Anatomy of* MAMMALIA.

This animal, ſome have ſuppoſed, is the prototype of all the fauns, ſatyrs, pans, and ſileni, deſcribed by the ancient poets, and whoſe forms are come down to us in the works of the painters, and ſculptors of antiquity; varied and embelliſhed according to the fancy of the authors. They ſeem to have been more numerous formerly than at preſent, if we credit the account of the large troop, to whom Alexander, when in India, prepared to give battle; and the attack made by Hanno on another large body, in an iſland on the coaſt of Africa, where he took three of the females, whoſe ſkins were depoſited in the temple of Juno, and found there by the Romans at the taking of Carthage. Vide Strab. lib. xv. and Hannonis Periplum, p. 77. ed. Hagæ, 1674.

Mr. Pennant apprehends, that the ſatyrs of the ancients were a ſpecies of monkey, and not the ſame with this animal; becauſe Ælian and Ptolemy affirm, that they had tails. See SIMIA aud CHIMPANZEE.

ORANIENBAUM, in *Geography*, a town of Germany, in the duchy of Anhault-Deſſau; 6 miles S.E. of Deſſau. N. lat. 51° 48′. E. long. 12° 28′.—Alſo, a town of Ruſſia, in the gulf of Finland, where is a royal palace, built by prince Menzikoff, afterwards converted into an hoſpital; but much uſed as a reſidence by the emperor Peter III.; 20 miles W. of Peterſburg. N. lat. 59° 52′. E. long. 29° 26′.

ORANIENBURG, a town of Brandenburg, in the Middle Mark, anciently called "Boetzow," ſituated on the Havel, and containing two churches. In 1699, a colony of the Vaudois, driven by perſecution on account of religion from their own country, was eſtabliſhed here. In 1671 the place was deſtroyed by fire; 18 miles N. of Berlin. N. lat. 52° 45′. E. long. 13° 19′.

ORANMORE, a poſt-town of Ireland, in the county of Galway; 98 miles W. by S. from Dublin, and 5 miles E. from Galway.

ORANSAY. See COLONSAY, and ORONSAY.

ORARIUM, in *Eccleſiaſtical Writers*, the ſame with *brandeum*.

ORARNE, in *Geography*, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 60° 42′. E. long. 17° 7′.

ORATAVA, a ſea-port town on the W. ſide of the iſland of Teneriffe, and the chief place of trade; the harbour of which is rendered unſafe by a N.W. wind: it contains one church and ſeveral convents; 5 miles N. of Laguna.

ORATION, a ſpeech or harangue, framed according to the rules of oratory, and ſpoken in public.

All the kinds of orations may be reduced to three heads; *viz.* *demonſtrative*, *deliberative*, and *judicial*. Ariſtotle is ſaid to be the author of this diviſion, which ſeems to be very juſt; ſince, perhaps, there is no ſubject of oratory, whether ſacred or civil, that may not be referred to one or other of theſe heads. It is a diviſion which runs through all the ancient

cient treatiſes on rhetoric, and is followed by the moderns who copy them. Dr. Blair, however, though upon the whole he approves and commends this diviſion, ſomewhat deviates from it; and prefers following that diviſion which the train of modern ſpeaking naturally points out to us, taken from the three great ſcenes of eloquence, popular aſſemblies, the bar, and the pulpit, each of which has a diſtinct character that particularly ſuits it. This diviſion coincides in part with the ancient one. The eloquence of the bar is preciſely the ſame with what the ancients called the judicial. The eloquence of popular aſſemblies, (for which ſee PUBLIC SPEAKING,) conſiſts moſtly of what the ancients term the deliberative ſpecies, and yet admits alſo of the demonſtrative. The eloquence of the pulpit (for which ſee PULPIT and ELOCUTION) is altogether of a diſtinct nature, and cannot be properly comprehended under any of the heads of the ancient rhetoricians. Adhering, however, to the ancient diſtribution, we obſerve that to the demonſtrative kind belong all ſuch diſcourſes as relate to the praiſe or diſpraiſe of perſons or things, as *panegyrics*, *invectives*, *genethliaca*, *epithalamia*, *epicedia*, *euchariſtiæ*, *epinicia*, *congratulations*, and *funeral orations*. See DEMONSTRATIVE.

To the deliberative kind belong whatever may become a ſubject of debate, conſultation, or advice, by means of *perſuaſion*, *diſſuaſion*, *exhortation*, and *commendation*. See DELIBERATIVE.

To the judicial kind belong all ſubjects which pertain to the ſecurity of property, the protection of innocence, the maintenance of juſtice, and puniſhment of crimes, by *accuſation*, *confirmation*, *confutation*, &c. See each under its proper article, CONFIRMATION, &c.

The judicial is the ſame with the eloquence of the bar employed in addreſſing judges, who have power to abſolve or condemn. In judicial affairs, both the Grecian and Roman youth who were deſirous to gain a reputation for eloquence, uſed commonly to give the firſt proofs of their genius and ability. The firſt of Cicero's orations now extant is his defence of Publius Quintius, which he ſpoke in the 26th year of his age. It was, indeed, at the bar that young orators uſed firſt to exerciſe and try their genius in public; and they took care to prepare themſelves for this, by declaiming beforehand, either in the ſchools, or under the inſtruction of ſome ſkilful perſon in private. In judicial controverſies there are two parties, the plaintiff or proſecutor, and the defendant or perſon charged. The ſubject is ſomething paſt; and the end propoſed by them Cicero calls "equity," or "right and equity;" the former of which ariſes from the laws of the country, and the latter from reaſon and the nature of things. As cauſes may ariſe from a great variety of things, writers have reduced them to three heads, which they call "States," to one of which all judicial proceedings may be referred. See an account of theſe ſtates, under the article CONTROVERSY.

All judicial cauſes are either *private* or *public*: that is, they relate to the right of particular perſons, and theſe are alſo called *civil* cauſes, as they are converſant about matters of property; or they are thoſe which relate to public juſtice and the government of the ſtate, and theſe are alſo called *criminal*, becauſe by them crimes are proſecuted, whether they be capital or of a leſs heinous nature. The "conjectural" ſtate (ſee CONTROVERSY) comes firſt in the order of inquiry; and when a perſon accuſed denies the fact, three things offer themſelves to the conſideration of the proſecutor: *viz.* Whether he *would* have done it, whether he *could*, and whether he *did* it. Hence ariſe three topics; from the *will*, the *power*, and the *ſigns*, or circumſtances which attended the action. The affections of the mind diſcover the *will*, ſuch as paſſion, an old grudge, a deſire of revenge, a reſentment of an injury, and the like. Under the ſecond head, or the *power* of doing a thing, are comprehended three things, *viz.* the place, the time, and the opportunity. The third head relates to the *ſigns* and circumſtances, which either preceded, accompanied, or followed the commiſſion of the fact. All theſe arguments, taken from conjectures, are called "preſumptions," which, though they do not directly prove that the accuſed perſon committed the fact with which he is charged; yet, when being laid together they appeared very ſtrong, ſentence might ſometimes be given by the Roman law upon them to convict him. Theſe are the topics from which the proſecutor deduces his arguments; and it is the buſineſs of the defendant to invalidate them. Sometimes the defendant not only denies that he did the fact, but charges it upon another. Thus Cicero in his oration for Roſcius, not only defends him from each of theſe three heads, but likewiſe charges the fact upon his accuſers. With regard to the *definitive* ſtate (ſee CONTROVERSY), the heads of argument are much the ſame to both parties. For each of them defines the fact in his own way, and endeavours to refute the other's definition. The third ſtate is that of *quality* (ſee CONTROVERSY), in which the diſpute turns upon the juſtice of an action. And here the defendant does not deny he did the thing with which he is charged, but aſſerts it to be right and equitable, from the circumſtances of the caſes, and the motives which induced him to do it. Sometimes a fact is rather excuſed than defended; by pleading that it was not done deſignedly, or with any ill intent: and this is called *conceſſion*, and includes *apology* and *intreaty*. The former repreſents the matter as the effect of inadvertency, chance, or neceſſity: and the latter is a ſubmiſſive addreſs to the equity and clemency of the court, or party offended, for pardon; as Cicero has done in his oration to Cæſar, in favour of Ligurius.

In the eloquence of the bar, or that which is employed in judicial caſes, the great object is conviction. Here it is not the ſpeaker's buſineſs to perſuade the judges to what is good or uſeful, but to ſhew them what is juſt and true; and of courſe it is chiefly, or ſolely to the underſtanding, that his eloquence is addreſſed. Beſides, ſpeakers at the bar addreſs themſelves to one, or to a few judges, who are perſons generally of age, gravity, and authority of character. And, moreover, the nature and management of the ſubjects which belong to the bar require a very different ſpecies of oratory from that of popular aſſemblies, for an account of which ſee PUBLIC SPEAKING. From the conſiderations here ſuggeſted it appears, that the eloquence of the bar is of a much more limited, more ſober, and chaſtened kind, than that of popular aſſemblies; and for ſimilar reaſons, the judicial orations of Cicero or Demoſthenes are not to be regarded as exact models of the manner of ſpeaking which is adapted to the preſent ſtate of the bar. The nature of the bar anciently, both in Greece and Rome, attained a much nearer approach to popular eloquence than what it now does. Strict law was much leſs an object of attention in ancient judicial orations than it is become among us. Eloquence, much more than juriſprudence, was the ſtudy of thoſe who were to plead cauſes: and, accordingly, Cicero ſays, that three months ſtudy was ſufficient to make any man a complete civilian; nay it was thought, that a perſon might be a good pleader at the bar, who had never ſtudied law at all. Beſides, the civil and criminal judges, both in Greece and Rome, were commonly much more numerous than they are with us, and formed a ſort of popular aſſembly.

ſembly. Thus the renowned tribunal of Areopagus at Athens conſiſted of at leaſt fifty judges. In Rome, the Prætor, who was the proper judge both in civil and criminal cauſes, named for every cauſe of moment, the "Judices ſelecti," as they were called, who were always numerous, and had the office and power of both judge and jury.

It ſhould be duly conſidered, that among us the foundation of a lawyer's reputation and ſucceſs muſt always be laid in a profound knowledge of his own profeſſion. Having laid this foundation by being well acquainted not only with the law in general, but by a knowledge of the cauſe which he is to plead in particular, he ſhould be appriſed, that eloquence in pleading is of the higheſt moment for giving ſupport to a cauſe. There is perhaps no ſcene of public ſpeaking where eloquence is more neceſſary; and the effect of good ſpeaking is always very great. Conſequently, of all the liberal profeſſions, there is not any one that gives fairer play to genius and abilities than that of the advocate. For his encouragement to application and exertion he may conſider, that he is ſure of coming forward according to his merit; for though intereſt and friends may ſet forward a young pleader with advantage at the beginning, they can merely open the field to him. A reputation reſting merely on theſe aſſiſtances will ſoon fall. Spectators obſerve, Judges decide, Parties watch; and to him will the multitude of clients never fail to reſort, who gives the moſt approved ſpecimens of his knowledge, eloquence, and induſtry. It is therefore of peculiar importance, that the eloquence adapted to the bar ſhould be properly underſtood. It is a firſt principle in this kind of eloquence, that both in ſpeaking or in writing law papers, it ſhould be of the calm and temperate kind, and connected with cloſe reaſoning. To thoſe who are beginning to practiſe at the bar, it ſhould be recommended, that they be careful to avoid verboſity, and that they form themſelves to the habit of a ſtrong and a correct ſtyle; which expreſſes the ſame thing better in a few words, than by the accumulation of intricate and endleſs periods. Diſtinctneſs is alſo a capital property in ſpeaking at the bar, and this ſhould be manifeſted, both in ſtating the queſtion, and in the order and arrangement of all the parts of the pleading. The narration of facts at the bar ſhould always be as conciſe as the nature of them will admit. When the pleader comes to refute the arguments employed by his adverſary, he ſhould be upon his guard not to do them injuſtice, by diſguiſing them, or placing them in a falſe light. The deceit is ſoon diſcovered, and will not fail of being expoſed. Whereas accuracy and candour in ſtating the arguments that have been uſed againſt him, before he proceeds to combat them, will create a ſtrong prepoſſeſſion in his favour. Wit may ſometimes be of ſervice at the bar, eſpecially in a lively reply, but a young pleader, who is too apt to be dazzled by it, ſhould take heed, that he does not reſt his ſtrength upon this talent. A proper degree of ardour and vehemence is always of uſe: it will have a good effect upon the cauſe, and induce the confidence of clients, for few of them will be fond of truſting their intereſts in the hands of a cold and unanimated ſpeaker. Nevertheleſs, his earneſtneſs and ſenſibility muſt not betray him into indecorum, and ſink him below that dignity of character, which it is of importance for every one in this profeſſion to ſupport. Above all, it ſhould never be forgotten, that there is no inſtrument of perſuaſion more powerful than an opinion of probity and honour in the perſon who undertakes to perſuade. This opinion of probity and honour muſt therefore be carefully preſerved, both by ſome degree of delicacy in the choice of cauſes, and by the manner of conducting them. Dr. Blair has given an analyſis of Cicero's oration "Pro Cluentio," which he recommends as an excellent example of managing at the bar a complex and intricate cauſe, with order, elegance, and force. Ward's Orat. vol. i. Blair's Lect. vol. ii. See ELOCUTION *of the Bar*.

A regular formal oration, or diſcourſe, for both theſe terms are ſynonimous, conſiſts of the following parts, *viz.* the exordium or introduction, the ſtate and the diviſion of the ſubject, or the propoſition, and enunciation of the ſubject, narration or explication, the reaſoning or arguments, the pathetic part, and the concluſion or peroration. See each under its proper head.

ORATION, *Funeral*. See FUNERAL and DEMONSTRATIVE.

ORATOR, a public ſpeaker, or a perſon who underſtands and practiſes the art of *oratory*; which ſee.

The diſpoſition and character and qualifications of the ſpeaker comprehend that part of oratory, or rather of invention, which Quintilian calls a "propriety of manners." They more eſpecially reſpect the proper means, by which he may conciliate the minds of his hearers, engage their affection, and recommend both himſelf and what he ſays to their good opinion and eſteem. There are four qualities, ſays Dr. Ward, more eſpecially ſuited to the character of an orator, which ſhould always appear in his diſcourſes, in order to render what he ſays acceptable to his hearers; and theſe are *wiſdom*, *integrity*, *benevolence*, and *modeſty*. An orator ſhould likewiſe well conſider the circumſtances of time and place, with the ſentiments and diſpoſitions of thoſe to whom he ſpeaks; which, according to Ariſtotle, may be diſtinguiſhed four ways, as they diſcover themſelves by the ſeveral *affections*, *habits*, *ages*, and *fortunes* of mankind. It is the orator's buſineſs to conſider theſe ſeveral characters and circumſtances of life, with the different bias and mode of thinking, which they give to the mind, that he may ſo conduct himſelf in his behaviour and manner of ſpeaking, as will render him moſt acceptable, and gain him the good eſteem of thoſe to whom he addreſſes his diſcourſe.

A true orator, ſays Dr. Blair, ſhould be a perſon of generous ſentiments, of warm feelings, and of a mind turned towards the admiration of all thoſe great and high objects, which mankind are naturally formed to admire. Joined with the manly virtues, he ſhould, at the ſame time, poſſeſs ſtrong and tender ſenſibility to all the injuries, diſtreſſes, and ſorrows of his fellow-creatures; a heart that can eaſily relent; that can readily enter into the circumſtances of others, and can make their caſe his own. A proper mixture of courage, and of modeſty, muſt alſo be ſtudied by every public ſpeaker. Modeſty is eſſential; it is always, and juſtly, ſuppoſed to be a concomitant of merit; and every appearance of it is winning and poſſeſſing. But modeſty ought not to run into exceſſive timidity. Every public ſpeaker ſhould be able to reſt ſomewhat on himſelf; and to aſſume that air, not of ſelf-complacency, but of firmneſs, which beſpeaks a conſciouſneſs of his being thoroughly perſuaded of the truth, or juſtice, of what he delivers; a circumſtance of no ſmall conſequence for making impreſſions on thoſe who hear. Next to moral qualifications, a fund of knowledge is moſt neceſſary to an orator. This is much inculcated both by Cicero and Quinctilian; "Quod omnibus diſciplinis et artibus debet eſſe inſtructus orator:" thus intimating that he ſhould have a liberal education, and be formed for his office by a regular ſtudy of philoſophy and the polite arts. Good ſenſe and knowledge are, indeed, the foundation of good ſpeaking. He who is to plead at the bar muſt make himſelf thoroughly maſter of the know-

ledge of the law; of all the learning and experience that can be uſeful in his profeſſion, for ſupporting a cauſe or convincing a judge. He, who is to ſpeak from the pulpit, muſt apply himſelf cloſely to the ſtudy of divinity, of practical religion, of morals, of human nature; that he may be rich in all the topics, both of inſtruction and perſuaſion. He who would fit himſelf for being a member of the ſupreme council of the nation, or of any public aſſembly, muſt be thoroughly acquainted with the buſineſs that belongs to ſuch aſſembly; he muſt ſtudy the forms of court, the courſe of procedure; and muſt attend minutely to all the facts that may be the ſubjects of queſtion or deliberation. But, beſides the knowledge immediately belonging to his profeſſion, a public ſpeaker ſhould extend his acquaintance with the general circle of polite literature. Moreover, without a habit of application and induſtry, it is impoſſible to excel in any thing; and much leſs to be a diſtinguiſhed pleader, or preacher, or ſpeaker in any aſſembly. Nothing can conduce ſo much to excite this kind of application as the honourable enthuſiaſm, or ardent attachment to the art in which excellence is ſought for, which characteriſed the great men of antiquity. Another circumſtance, that will greatly contribute to improvement, is attention to the beſt models; an attention very different from that ſlaviſh imitation, which depreſſes genius, or betrays the want of it; an attention, which will ſerve to correct and enlarge our own ſtock of ideas, and which will excite a laudable emulation to be diſtinguiſhed in ſtyle, compoſition, and delivery. It ſhould be remembered, while we are endeavouring to profit by models of eloquence, that the ſtyle of writing and that of ſpeaking are different, and that the ſtyle of approved authors in writing diſcourſes ſhould not be transferred to popular orations. Among authors, whoſe manner of writing approaches nearer to the ſtyle of ſpeaking than others, Dr. Blair mentions dean Swift, and lord Bolingbroke. Beſides attention to the beſt models, thoſe, who aſpire to be diſtinguiſhed orators, muſt accuſtom themſelves to the exerciſe both of compoſing and ſpeaking, as a neceſſary means of improvement. To all that has been already ſaid on the beſt method of forming an accompliſhed orator, Dr. Blair directs the candidate for fame in this way to the ſtudy of critical and rhetorical writers, which will ſerve to aid his improvement in the practice of eloquence. He particularly recommends the original ancient writers. Ariſtotle, he ſays, by his comprehenſive genius laid a foundation for all that was afterwards written on the ſubject; and he was the firſt who took rhetoric out of the hands of the Sophiſts, and introduced reaſoning and good ſenſe into the art. His "Treatiſe on Rhetoric" deſerves attentive peruſal. Two ſucceeding Greek rhetoricians ſtill remain, though moſt of them are loſt: theſe are Demetrius Phalereus and Dionyſius of Halicarnaſſus; both have written on the conſtruction of ſentences and merit attention; eſpecially Dionyſius, who is a very accurate and judicious critic. It is needleſs, in this connection, to recommend the rhetorical writings of Cicero, and particularly his three books "De Oratore." But of all the ancient writers on the ſubject of oratory the moſt inſtructive and moſt uſeful is Quintilian; whoſe "Inſtitutions" abound with good ſenſe, and diſcover a very high degree of juſt and accurate taſte; whilſt they comprehend almoſt all the principles of good criticiſm. Ward and Blair, ubi ſupra.

ORATORIO, Ital. *Oratoire*, Fr. *Oratorium*, Lat. a ſacred drama in Latin, or any national language, divided into ſcenes, and uſually in three acts or parts, in imitation of theatrical pieces, but always written on ſacred ſubjects, taken from ſcripture, or church hiſtory, and ſet to a grave and ſolemn muſic, in order to be performed vocally, and inſtrumentally, in a church, or elſewhere, during Lent. This cuſtom, ſays Rouſſeau, is inadmiſſible in France. French muſic is ſo undramatical, that it is enough to be allowed to expoſe itſelf in the theatres, without exhibiting its defects in the church. Riſe and Progreſs of the ſacred muſical Drama, or Oratorio.

The firſt rappreſentatione, or exhibition truly dramatic, that was performed in Italy, according to Apoſtolo Zeno, was a ſpiritual comedy, at Padua, 1243, 1244. (Bibl. Ital. p. 487.) Another Repreſentation of the Myſteries of the Paſſion of Chriſt, &c. according to Muratori, was performed at Friuli, 1298. (Script. Rer. Ital. vol. xxiv. p. 1205.) In 1264, was inſtituted at Rome the Compagnia del Gonfalone, the ſtatutes of which were printed in that city 1554, and of which the principal employment was to act or repreſent the ſufferings of our Lord, in Paſſion-week, an inſtitution which was long continued there. See Riccoboni's Reflex. hiſt. et crit. ſur les differens Theatres d'Europe; et Trattato dell' Opera in Muſica del Cavalier Planelli, § i. cap. 1.

According to Villani, Vaſari, Cionacci, and Creſcimbeni, *la rappreſentatione ſacra teatrale* had its beginning in Tuſcany. (See Signorelli's Storia crit. de' Teatri, p. 189.) Tiraboſchi, Storia della Letterat. Ital. tom. v. l. iii. cap. 3. claims the origin and invention of every ſpecies of drama for the Italians. However, the ingenious and agreeable author of the Biog. Dramatica, or Companion to the Playhouſe, (Introd. p. 9.) obſerves, that "thoſe who imagine the Engliſh to have been later in the cultivation of the drama than their neighbours, will, perhaps, wonder to hear of theatrical entertainments almoſt as early as the Conqueſt; and yet nothing is more certain, if we may believe an honeſt monk, one William Stephanides, or Fitz-Stephen, in his Deſcriptio Nobiliſſimæ Civitatis Londinæ, who writes thus: London, inſtead of common interludes belonging to the theatre, has plays of a more holy ſubject: repreſentations of thoſe miracles which the confeſſors wrought, or of the ſufferings, wherein the glorious conſtancy of the martyrs appeared. This author was a monk of Canterbury, who wrote in the reign of Henry II. and died in that of Richard I. 1191; and as he does not mention theſe repreſentations as novelties to the people, for he is deſcribing all the common diverſions in uſe at that time, we can hardly fix them lower than the Conqueſt; and this, we believe, is an earlier date than any other nation of Europe can produce, for their theatrical repreſentations."

Le Chant Royal was invented in France about 1380; it conſiſted of verſes to the virgins and ſaints, ſung in chorus by troops or companies of pilgrims returning from the holy ſepulchre. Meneſtrier, des Repreſentations en Muſ.

There were myſteries repreſented in Germany 1322. And in the ſame century, 1378, the eccleſiaſtics and ſcholars of St. Paul's ſchool exhibited ſimilar interludes in England.

But though every nation in Europe ſeems, in the firſt attempts at dramatic exhibitions, to have had recourſe to religious ſubjects, and an oratorio, or ſacred drama, is but a myſtery or morality in muſic, yet thoſe that were written before the ſeventeenth century ſeem never to have been entirely ſung; but chiefly declaimed, with incidental airs and choruſes. The late Rev. and learned Mr. Crofts, and the honourable Topham Beauclerc, in their curious libraries had collected a great number of theſe religious poems or myſteries, in Italian, of which we procured many of the moſt ancient, at the ſale of their books, in order to trace the origin of the ſacred muſical drama. Some of them, by the groſs manner in which the ſubjects are treated, the coarſeneſs

of

of the dialogue, and ridiculous ſituation into which the moſt ſacred perſons and things are thrown, ſeem, though printed ſoon after the invention of the preſs, to be much more ancient than that diſcovery.

Gio Battiſta Doni (Trattato della Muſica Scenica, c. vi. p. 15. Op. omn. tom. ii. S. Giovanni e Paolo, one of the Collect. was written by Lorenzo il Magnifico: Santa Domitilla, and Santa Guglielma, by Antonia, wife of the poet Pulci, in the fifteenth century); ſpeaking of oratorios, ſays that by a *ſpiritual repreſentation* he does not mean that groſs, vulgar, and legendary kind of drama uſed by the nuns and monks in convents, which deſerve not the name of poetry; but ſuch elegant and well conſtructed poetical fables as that of St. Alexis, by the ingenious Giulio Roſpiglioſi, many times repreſented, and always received with great applauſe. This oratorio, which is omitted in the Drammaturgia, though printed in ſcore, in folio, 1634, was ſet to muſic by Stefano Landi, of the Papal chapel, and performed at the Barberini palace in Rome, on a ſtage, and in action, with dances, machinery, and every kind of dramatic decoration, of which a ſplendid account is given in a preface and letter prefixed to the work.

This deſcription ſeems to comprehend the poetical virtues and vices of all ancient and modern religious dramas. The abbé Arnaud, in his Eſſai ſur le Theatre Anglois, (Varietées Litt. tom. i. p. 29.), ſays that the fathers of the church in the firſt ages of Chriſtianity, indulging the paſſion of the people for public ſpectacles, oppoſed religious dramas, built on the ſacred writings, to the profane, which had been long uſed by the Pagans.

At the revival of theatrical amuſements, when the reformers began to diſſeminate their doctrines throughout Europe, religious plays were made the vehicles of opinion, both by the Catholics and Proteſtants; and there are Latin dramas of this kind, as well as others in modern languages, extant, which might with propriety be called oratorios. At the beginning of the Reformation in England, it was ſo common for the defenders of the old and new doctrines to avail themſelves of plays compoſed on ſubjects of ſcripture, in which they mutually cenſured and anathematiſed each other, that an act of parliament paſſed in the twenty-fourth year of Henry VIII. to prohibit the acting or ſinging any thing in theſe interludes contrary to the eſtabliſhed religion. It appears, however, in Collyer's Hiſtory of the Reformation, that after this period, the myſteries of the Roman Catholic religion were ridiculed by the Proteſtants, on a ſtage, in churches. It is related by Cardan, in his eloge of our young king, Edward VI., that he had written a moſt elegant comedy, called The Whore of Babylon. The number of comedies, and tragi-comedies, written about this time, is incredible; they are, however, ſaid to have been even more extravagant and groſs, than numerous. One is entitled, Jeſus the true Meſſiah, a comedy; another, The new German Aſs of Balaam; the Calviniſtical Poſtilion; the Chriſtian Cavalier of Eiſlebn, a delectable, ſpiritual comedy, including the hiſtory of Luther and his two greateſt enemies, the pope and Calvin; A pleaſant comedy of the true old Catholic and Apoſtolic church, &c. Storia Crit. de' Teatri, p. 248.

The Converſion of St. Paul, performed at Rome, 1440, as deſcribed by Sulpicius, has been, erroneouſly, called the *firſt* opera, or muſical drama. (Hiſt. de la Muſ. tom. i. p. 241. and Meneſtrier, ſur les Repreſ. en Muſ.) Abram et Iſaac ſuo Figliuolo, a ſacred drama (*azione ſacra*) "ſhewing how Abraham was commanded by God to ſacrifice his ſon Iſaac on the mountain," was performed in the church of St. Mary Magdalen in Florence, 1449. Another on the ſame ſubject, called Abraham and Sarah, "containing the good life of their ſon Iſaac, and the bad conduct of Iſhmael, the ſon of his hand-maid, and how they were turned out of the houſe," was printed in 1556. Abele Caino, and Sampſon, 1554; The Prodigal Son, 1565; and La Commedia Spirituale dell' Anima, "The Spiritual Comedy of the Soul," printed at Siena, but without date; in which there are near thirty perſonifications, beſides St. Paul, St. John Chryſoſtom, two little boys who repeat a kind of prelude, and the announcing angel who always ſpeaks the prologue in theſe old myſteries. He is called *l'angelo che nunzia*, and his figure is almoſt always given in a wooden cut on the title-page of printed copies. Here, among the interlocutors, we have God the Father, Michael the archangel, a Chorus of Angels, the human Soul with her guardian Angel, Memory, Intellect, Free-will, Faith, Hope, Charity, Reaſon, Prudence, Temperance, Fortitude, Juſtice, Mercy, Poverty, Patience, and Humility: with Hatred, Infidelity, Deſpair, Senſuality, a Chorus of Dæmons, and the Devil.

None of theſe myſteries are totally without muſic, as there are choruſes and *laudi*, or hymns, that are ſung in them all, and ſometimes there was playing on inſtruments between the acts. In a play written by Damiano and printed at Siena, 1519, according to Creſcimbeni, tom. i. p. 107, at the beginning of every act there was an octave ſtanza, which was ſung to the ſound of the lyra viol, by a perſonage called Orpheus, who was ſolely retained for that purpoſe; at other times a madrigal was ſung between the acts, after the manner of a chorus.

It was, however, by ſmall degrees that entire muſical myſteries had admiſſion into the church, or were improved into oratorios. All the Italian writers on the ſubject agree, that theſe ſacred muſical dramas had their beginning in the time of San Filippo Neri, who was born 1515, and founded the congregation of the Prieſts of the Oratory at Rome, in 1540. This ſaint, who died 1595, is numbered among Italian improviſatori, by Quadrio, tom. i. p. 163. He was originally intended for a merchant, but was drawn from commercial purſuits by Vocation. *Oratorio*, Ital. *Oratorium*, Lat. implies a ſmall chapel, or particular part of a houſe or church, where there is an altar. The ſpaces between the arches of Romiſh churches, are called *Oratorii*, Ital. *Oratoires*, Fr. Anglicè chapels. The Congregation of the Oratory, eſtabliſhed at Rome, and in ſome other cities of Italy by S. Phil. Neri, about 1558, originated from the conferences which this pious eccleſiaſtic held in his own chamber at Rome. The great number of perſons who attended theſe meetings obliged St. Phil. to requeſt the adminiſtrators of the church of San Girolamo della Carità to grant permiſſion to hold theſe aſſemblies there, which was granted. In 1574, they were transferred to the church of the Florentines; and in 1583 to Santa Maria della Vallicella. By degrees this eſtabliſhment ſpread itſelf all over Italy, where it has ſtill many houſes. The members are bound by no vow. Dict. des Cultes Relig.

It appears that theſe fathers, in whatever city of Italy they had an eſtabliſhment, entertained their congregations with good muſic. During the ſervice, and after ſermon, it was uſual for them, among other pious exerciſes, in order to draw youth to church, and keep them from ſecular amuſements, to have hymns, pſalms, and other ſpiritual *laudi*, or ſongs, ſung either in chorus, or by a ſingle favourite voice, divided into two parts, the one performed before the ſermon, and the other after it.

But though this devout practice was begun in ſo ſimple a manner, with only ſpiritual cantatas, or ſongs, on moral ſubjects; in order to render the ſervice ſtill more attractive,

ſome ſacred ſtory or event from ſcripture was written in verſe, and ſet by the beſt poets or muſicians of the times. Theſe being compoſed in dialogue, and rendered intereſting to the congregation, ſuch curioſity was excited by the performance of the firſt part, that there was no danger during the ſermon that any of the hearers would retire, before they had heard the ſecond.

The ſubjects of theſe pieces were ſometimes the good Samaritan; ſometimes Job and his friends; the prodigal ſon; Tobit with the angel, his father and his wife, &c. All theſe, by the excellence of the compoſition, the band of inſtruments, and the performance, brought this oratory into ſuch repute, that the congregations became daily more and more numerous. And hence this ſpecies of ſacred muſical drama, wherever performed, in proceſs of time, obtained the general appellation of oratorio. In the church of San Girolamo della Carita at Rome, oratorios are ſtill conſtantly performed on Sundays and feſtivals from All Saints Day till Palm Sunday; as well as in the church of La Vallicella, or la Chieſa Nuova, where they are likewiſe performed from the firſt of November till Eaſter; Oratorj in Muſica, e ſermoni, every evening on all feſtivals. (See Roma moderna by Venuti, 1766, p. 207.) Theſe are the two churches in which ſuch ſpiritual ſpectacles had their beginning; but the practice has ſince been ſo much extended to the other churches of Rome, that there is not a day in the year on which one or more of theſe performances may not be heard. And as liſts of oratorios and other *Funzioni* to be performed in the ſeveral churches in the courſe of the year are publiſhed, like our liſts of Lent preachers, great emulation is excited in the directors and performers, as well as curioſity in the public. The firſt collection of the words of hymns and pſalms, ſung in the chapel of San Filippo Neri, was publiſhed at Rome 1585, under the title of Laudi ſpirituali ſtampate ad iſtanza de' R R. P. P. della Congregatione dell' Oratorio. The ſecond in 1603: Laudi Spirituali di diverſi, ſolite cantarſi dopo Sermoni da' P P. della Cong. dell' Oratorio; among theſe were dialogues, in a dramatic form. (Creſcimbeni, Introd. all' Iſtor. della Volg. Poeſia. vol. i. lib. iv. p. 256.) See MYSTERIES and MORALITIES, which were often dramatized and formed into oratorios for convents and churches, and performed on feſtivals.

ORATORY is the art of ſpeaking well, upon any ſubject, in order to perſuade; and to ſpeak well, as Cicero explains it, is to ſpeak juſtly, methodically, floridly, and copiouſly. In which ſenſe the word imports the ſame with *rhetoric*; the difference between the two only conſiſting in this, that one is taken from the Greek language, and the other from the Latin. However, the caſe is not preciſely the ſame with the words *rhetorician* and *orator*. For although the Grecians uſed the former to expreſs both thoſe who taught the art, and ſuch as practiſed it; yet the Romans afterwards, when they adopted that word into their language, confined it to the teachers of the art, and called the reſt *orators*.

Lord Bacon defines rhetoric, or oratory, to be the art of applying and addreſſing the dictates of reaſon to the fancy, and of ſo recommending them as to affect the will and deſires. The end of rhetoric, he obſerves, is to fill the imagination with ideas and images, which may aſſiſt nature, without oppreſſing it.

Voſſius defines rhetoric, the faculty of diſcovering what every ſubject affords of uſe for perſuaſion. Hence, as every author muſt invent arguments to make his ſubjects prevail; diſpoſe thoſe arguments, thus found out, in their proper places; give them the embelliſhments of language proper to the ſubject; and, if this diſcourſe be for public delivery, utter them with that decency and force which may ſtrike the hearer; *rhetoric*, or *oratory*, becomes divided into four parts, *viz. invention*, *diſpoſition*, *elocution*, and *pronunciation*; which ſee reſpectively.

As to the hiſtory of oratory, the firſt invention of it is aſcribed by the Egyptians, and fables of the poets, to Mercury. Quinctilian obſerves, with reſpect to the origin of this art, that we derive the faculty of ſpeech from nature; but the art from obſervation; and that men, perceiving that ſome things in diſcourſe are ſaid to advantage, and others not, accordingly marked thoſe things, in order to avoid the one, and imitate the other: and that they alſo added ſome things from their own reaſon and judgment, which being confirmed by uſe, they began to teach others what they knew themſelves. But it is not known when this method of obſervation firſt took place. It is reaſonable to believe, that the Greeks had the principles of this art ſo early as the time of Pittheus, whoſe nephew Theſeus lived not long before the taking of Troy. And at this time Cicero thought it was in much eſteem among them. After this period, there is a great chaſm in the hiſtory of oratory: for Quinctilian ſays, that afterwards Empedocles, who flouriſhed about five hundred years after Troy was taken, is the firſt upon record who attempted any thing concerning it. About this time there aroſe ſeveral maſters of this art, the chief of whom Quinctilian has enumerated; as Corax and Tiſias, of Sicily; Gorgias, of Leontium, in the ſame iſland, the ſcholar of Empedocles; Thraſymachus, of Calcedon; Prodicus, of Cea; Protagoras, of Abdera; Hippias, of Elis; Alcidamus, of Elea; Antiphon, who firſt wrote orations; Polycrates, and Theodore of Byzantium. Nor ſhould we omit Plato, whoſe elegant dialogue, entitled Gorgias, is ſtill extant. To theſe ſucceeded Iſocrates, the moſt renowned of the ſcholars of Gorgias, extolled by Cicero as the greateſt maſter and teacher of oratory; Ariſtotle, whoſe ſyſtem of oratory is eſteemed the beſt and moſt complete of any in the Greek language; Demoſthenes, who was an auditor of Iſocrates, Plato, and Iſæus, and who has been eſteemed by the beſt judges the prince of Grecian orators; Æſchines, who taught rhetoric at Rhodes; Theodectes and Theophraſtus, diſciples of Ariſtotle; Demetrius Phalereus, ſcholar of Theophraſtus; Hermagoras; Athenæus; Apollonius Molon; Areus Cæcilius; Dionyſius, of Halicarnaſſus; Apollonius, of Pergamus; and Theodore of Gadara. Of theſe there now remains nothing upon the ſubject of oratory, except ſome tracts of Dionyſius, who flouriſhed in the reign of Auguſtus Cæſar. After the time of Quinctilian we may mention Hermogenes, and Longinus, the author of the excellent treatiſe "Of the Sublime."

This art was introduced late, and with difficulty among the Romans. In the year of their city 592, when, by the induſtry of ſome Grecians, the liberal arts began to flouriſh in Italy, a decree paſſed the ſenate, by which all philoſophers and rhetoricians were ordered to depart out of Rome: but in a few years after, on the arrival of certain ambaſſadors, *viz.* Carreades, Critolaus, and Diogenes, who were orators as well as philoſophers, from Athens to Rome, the Romans were ſo charmed with the eloquence of their harangues, that they could no longer be reſtrained from purſuing the ſtudy of oratory. According to Seneca, Lucius Plotius, a Gaul, was the firſt who taught the art of oratory, at Rome, in Latin, and the firſt Roman who engaged in it was Blandus, of the equeſtrian order; and he was ſoon ſucceeded by others; ſome of whoſe lives are yet extant, written by Suetonius, as many of the Grecians are by Philoſtratus and Eunapius. The writers on this art, enumerated by Quinctilian, were M. Cato, the cenſor, and after him Anthony, the orator; but he who carried eloquence to its higheſt pitch

was Cicero, who has likewiſe, by his rules, given the beſt plan, both to practiſe and teach the art. He alſo mentions Cornificius, Stertinius, Gallio the father, Celſus, Lenas, Virginius, Pliny, and Rutilius.

Quinctilian himſelf deſerves the higheſt commendation for diligence and accuracy as a writer; of whom St. Jerom ſays, that he was the firſt who taught publicly at Rome, and received a ſalary from the treaſury. This he places in the eighth year of Domitian; whereas Suetonius informs us, that Veſpaſian was the firſt who granted out of the treaſury a yearly ſalary of near 800*l.* ſterling, to the Latin and Greek rhetoricians. Since the revival of learning, there has been a great number of writers, who have treated on the ſubject of oratory, and contributed to the perfection of it, both in theory and practice.

Having rapidly enumerated the principal orators of antiquity, both in Greece and Rome, we ſhall now mention ſome peculiar circumſtances which contributed at different periods and in different countries to call forth into exerciſe their powers of eloquence, and to give them their celebrity. Eloquence, or oratory, being the art of ſpeaking in ſuch a manner as to attain the end for which we ſpeak, its power will chiefly appear when it is employed to influence conduct, and to perſuade to action; and in this view it may be conciſely defined, "the art of perſuaſion." A popular writer has diſtinguiſhed three kinds, or degrees, of eloquence; for an account of which, ſee ELOQUENCE. It has been obſerved by ſeveral authors, that eloquence is to be looked for only in free ſtates. This obſervation is appropriately and beautifully illuſtrated by Longinus. Liberty, he ſays, is the nurſe of true genius; it animates the ſpirit, and invigorates the hopes of men; excites honourable emulation, and a deſire of excelling in every art. All other qualifications you may find among thoſe who are deprived of liberty; but never did a ſlave become an orator; he can only be a pompous flatterer. Theſe obſervations, under certain limitations, are juſtified by hiſtory and obſervation. For although under arbitrary governments, that are civilized, and that encourage the arts, ornamental eloquence may flouriſh, that eloquence which is calculated more to ſoothe and pleaſe, than to convince and perſuade; yet high, manly, forcible eloquence is to be looked for only, or chiefly, in the regions of freedom. Eloquence, or the art of perſuaſion, took its riſe with that of the Grecian republics. The flouriſhing period of the Grecian ſtates laſted from the battle of Marathon till the time of Alexander the Great, who ſubdued the liberties of Greece. This period comprehends about 150 years, and within it are to be found moſt of their poets and philoſophers, but chiefly their orators. Of theſe Grecian republics the moſt noted for eloquence, as well as for arts of every kind, was that of Athens. The genius of the government of the Athenians was democratical, and affairs were conducted among them by reaſoning and ſpeaking, and by a ſkilful application to the paſſions and intereſts of a popular aſſembly.

In ſuch a ſtate, and among ſuch a people, eloquence, that kind of eloquence which was moſt effectual for convincing, intereſting, and perſuading the hearers, would be much ſtudied, as the ſureſt means of riſing to influence and power. Piſiſtratus, who was contemporary with Solon, and ſubverted his plan of government, is mentioned by Plutarch as the firſt who diſtinguiſhed himſelf among the Athenians by application to the arts of ſpeech; and in this way he roſe to the ſovereign power. Of ſucceeding orators we have no particular account till the commencement of the Peloponneſian war, when Pericles appeared, and carried eloquence to a great height; to ſuch a height that he was never afterwards ſurpaſſed. His eloquence was ſo forcible and vehement, that it triumphed over the paſſions and affections of the people; and he was therefore called Olympius, and is ſaid, like Jupiter, to have thundered when he ſpoke. Suidas mentions one remarkable circumſtance relating to Pericles, that he was the firſt Athenian who compoſed, and put into writing, a diſcourſe deſigned for the public. After Pericles, in the courſe of the Peloponneſian war, aroſe Cleon, Alcibiades, Critias, and Theramenes, eminent citizens of Athens, who, though not orators by profeſſion, were all diſtinguiſhed for their eloquence. The ſtyle of oratory which then prevailed, appears from the orations in the hiſtory of Thucydides, who flouriſhed in the ſame age; it was manly, vehement, and conciſe, approaching even to ſome degree of obſcurity. After the days of Pericles, the reputation and influence which the powers of eloquence acquired, gave birth to a ſet of men, called Rhetoricians, or Sophiſts, who appeared in great number during the Peloponneſian war; ſuch were Protagoras, Prodicus, Thraſymus, and Gorgias. Theſe men profeſſed the art of giving receipts for making all ſorts of orations, for or againſt any cauſe whatever. They were the firſt who, with this view, treated of common places, and the artificial invention of arguments and topics for every ſubject. Accordingly they may be juſtly deemed the firſt corruptors of true eloquence; and they were oppoſed by Socrates, who endeavoured to explode their ſophiſtry. In the ſame age with the philoſopher juſt mentioned, flouriſhed Iſocrates, whoſe writings are ſtill extant. As a profeſſed rhetorician he acquired a great fortune and higher favour than any of his competitors, by teaching eloquence. His orations abound with morality and good ſentiments; they are flowing and ſmooth; but too deſtitute of vigour. For a further account of him, ſee his biographical article. To this period belong alſo Iſæus and Lyſias. (See their articles.) The former is diſtinguiſhed for being the maſter of Demoſthenes, who raiſed eloquence to a higher degree of ſplendour than any other perſon who ever bore the name of an orator. For the circumſtances of his life, and the character of his eloquence, particularly compared with that of Cicero, and contraſted againſt that of Æſchines, ſee his biographical article. After the days of Demoſthenes, Greece loſt her liberty, and eloquence of courſe languiſhed and relapſed again into the feeble manner introduced by the rhetoricians and ſophiſts. Demetrius Phalereus, who lived in the next age to Demoſthenes, attained ſome character, but he is repreſented as a flowery rather than a perſuaſive ſpeaker, who aimed at grace rather than ſubſtance. "He amuſed the Athenians," ſays Cicero, "rather than warmed them." After his time we hear of no more Grecian orators of any note.

If we advert to the riſe and progreſs of eloquence among the Romans, we ſhall find that they were long a martial nation, altogether rude, and unſkilled in arts of any kind. The Romans always acknowledged the Grecians as their maſters in every part of learning. To this purpoſe Horace ſpeaks of them in his Epiſt. ad Aug.

> "When conquer'd Greece brought in her captive arts,
> She triumph'd o'er her ſavage conquerors' hearts;
> Taught our rough verſe its numbers to refine,
> And our rude ſtyle with elegance to ſhine."
>
> Francis.

As the Roman government, during the republic, was of the popular kind, public ſpeaking became at an early period an engine of government, and was employed for gaining diſtinction and power. But in the rude unpoliſhed times of the ſtate, their ſpeaking could hardly be deemed eloquence.

quence. It was not till a ſhort time preceding the age of Cicero, that the Roman orators roſe into any note. Craſſus and Antonius, to whom we may add Hortenſius, appear to have been the moſt eminent. Cicero has deſcribed the character of their eloquence. Cicero himſelf is at this period the object moſt worthy of our attention; and his name alone ſuggeſts every thing that is ſplendid in oratory. For his character as an orator, we refer to his biographical article. The reign of eloquence, among the Romans, was very ſhort. After the age of Cicero, it not only long languiſhed but expired: nor need we wonder that this ſhould be the caſe. For not only was liberty entirely extinguiſhed, but arbitrary power was felt in its heavieſt and moſt oppreſſive weight: Providence having in its wrath delivered over the Roman empire to a ſucceſſion of ſome of the moſt execrable tyrants that ever diſgraced and ſcourged the human race. The change which was produced in eloquence by the nature of the government and the ſtate of the public manners, is beautifully deſcribed in the dialogue "De Cauſis corruptæ Eloquentiæ," attributed by ſome to Tacitus, by others to Quinctilian. In the ſchools of the declaimers, the corruption of eloquence was completed. Thus, with the Greek rhetoricians, the manly and ſenſible eloquence of their firſt noted ſpeakers degenerated into ſubtility and ſophiſtry; and among the Roman declaimers, it paſſed into the quaint and affected; into point and antitheſis. This corrupt manner begins to appear in the writings of Seneca; and ſhews itſelf alſo in the famous panegyric of Pliny the Younger on Trajan, which may be conſidered as the laſt effort of Roman oratory. In the decline of the Roman empire, the introduction of Chriſtianity gave riſe to a new ſpecies of eloquence, in the apologies, ſermons, and paſtoral writings of the fathers of the church. Among the Latin fathers, Lactantius and Minutius Felix are the moſt remarkable for purity of ſtyle; and in a later age, the famous St. Auguſtine poſſeſſes a conſiderable ſhare of ſprightlineſs and ſtrength. But none of the fathers afford any juſt models of eloquence. Among the Greek fathers, the moſt diſtinguiſhed, in a high degree, for his oratorical merit, is St. Chryſoſtom. See his biographical article.

In modern times, and even in Great Britain, we are unqueſtionably inferior, in a variety of reſpects, to the Greeks and Romans. They aſpired to a more ſublime ſpecies of eloquence than the moderns. Theirs was of the vehement and paſſionate kind; that of the moderns is much more cool and temperate; and in our country eſpecially, it has confined itſelf almoſt wholly to the argumentative and rational. The reaſons of this change are detailed by Dr. Blair in his Lectures, &c. vol. ii.

We ſhall cloſe this article with obſerving, in the words of a very good judge, that the method of forming the beſt ſyſtem of oratory is to collect it from the fineſt precepts of Ariſtotle, Cicero, Quinctilian, Longinus, and other celebrated authors; with proper examples taken from the choiceſt parts of the pureſt antiquity. On this plan, the learned Dr. Ward has formed his ſyſtem, to which we refer the reader, and on the ſubject of this article to his firſt lecture, vol. i. Concerning the diſtribution of the ſubject of oratory, and different kinds of orations, ſee ORATION.

ORATORY is alſo uſed, among the Romans, for a cloſet, or little private apartment, in a large houſe, near a bedchamber, furniſhed with a little altar, and a book-ſtand for private devotion.

The ancient oratories were little chapels, adjoining to monaſteries, wherein the monks ſaid prayers, before they had any churches. Several councils and ſynods have condemned the uſe of private oratories.

In the ſixth and ſeventh centuries, oratories were little churches, frequently built in burial-grounds, without either baptiſtery, cardinal prieſt, or any public office; the biſhop ſending a prieſt to officiate occaſionally.

ORATORY is alſo uſed for a ſociety or congregation of devout perſons, who form a kind of monaſtery, and live in community; but without being obliged to make any vows. Hence,

ORATORY, *Prieſts of the*, a community of ſecular prieſts, who live together in a monaſtic manner, but without vows. They were firſt eſtabliſhed at Rome, about the year 1540, by St. Philip Neri, a Florentine, under the title of "Oratory of Sancta Maria in the Valicella."

The name of this religious ſociety was derived from an apartment, accommodated in the form of an oratory, or cabinet for devotion, which S. Philip Neri built at Florence for himſelf, and in which for many years he held ſpiritual conferences with his more intimate companions.

On the model of this the cardinal Berulle eſtabliſhed a congregation of the Oratory of Jeſus, in 1613, in France, which has ſince increaſed: ſo that there aroſe ſixty houſes of Prieſts of the Oratory, in that kingdom.

The fathers, or Prieſts of the Oratory, are not, properly ſpeaking, religious or monks, being bound by no vows, and their inſtitute being purely eccleſiaſtical or ſacerdotal.

There is ſome difference, however, between the Italian and French inſtitutions. S. Philip Neri, to prevent the confuſion which the great number of houſes uſually occaſioned in congregations, would have his to be a ſingle houſe: and though others were at liberty to form the like congregations, yet they were to have no dependence on one another.

For this reaſon, the houſes of the Oratory, in Italy and Flanders, are all independent; whereas, thoſe in France have a relation to each other, and all depend on the ſame chief, who has the quality of ſuperior-general; and, with three aſſiſtants, governs all the congregations.

ORAVAIS, in *Geography*, a town of Sweden, in Eaſt Bothnia; 22 miles N. of Waſa.

ORAWITZA, a river of Hungary, which runs into the Waag; 9 miles N. of Arva.

ORAYOI, a town of New Mexico; 150 miles W. of Santa Fé.

ORB, ORBIS, in *Aſtronomy*, a ſpherical body or ſpace, contained under two ſuperficies; the one concave the other convex.

The ancient aſtronomers conceived the heavens as conſiſting of ſeveral vaſt azure tranſparent orbs or ſpheres, incloſed in one another; or vaſt circles, which in their areas included the bodies of the planets; the radii of which were compriſed between the centre of the earth, and the higheſt point to which the planets riſe, ſuppoſing the earth to be in the centre.

There are orbs *concentric*, i. e. having the ſame centre; and orbs *eccentric*.

The *magnus orbis*, or great orb, is that in which the ſun is ſuppoſed to revolve; or, rather, it is that in which the earth makes its annual circuit.

ORB, in *Aſtrology*. An orb of light is a certain ſphere, or extent of light, which the aſtrologers allow a planet beyond its centre.

They ſay, that, provided the aſpects do but fall within this orb, they have almoſt the ſame effect as if they pointed directly againſt the centre of the planet. See ASPECT.

The orb of Saturn's light they make to be 10 degrees; that of Jupiter 12 degrees; that of Mars 7 degrees 30 minutes; that of the Sun 17 degrees; that of Venus 8 de-

grees; that of Mercury 7 degrees; that of the Moon 12 degrees 30 minutes.

Orb, in *Pointed Architecture*, the ſame as knot or boſs. See Knot.

Orb, in *Tactics*. See *Round* Battalion.

Orb, in *Geography*, a river of France, which riſes in the N. part of the department of the Allier; 8 miles N.W. of Lodeve, and runs into the Mediterranean, 8 miles below Beziers.

ORBE, a river of Switzerland, which riſes in mount Jura, paſſes the lake of Neufchatel and Bienne, and runs into the Aar; 3 miles W. of Buren, in the canton of Berne.—Alſo, a town of Switzerland, in the canton of Berne, ſituated on the above river. According to antiquaries, this was the moſt ancient town, and once the moſt powerful of all Helvetia: it was called "Urba," and was the capital of the "Pagus Urbigenus;" but it has no remains of its ancient ſplendour. Some antique fortifications, an old caſtle, and a round tower, are probably works of later times, when this country was divided into a number of feudal ſovereignties. The ſituation of the town is romantic; its ſingle-arched bridge projecting over the Orbe, the wild ſcenery on the banks of this river, the frequent cataracts, and the pictureſque view in the environs, are all intereſting objects. Orbe, which is governed by its own magiſtrates, is compriſed within the bailliage of Echalons, belonging to Berne and Friburgh. In this town is an infirmary, formed by M. Venel, an eminent ſurgeon, for the reception of perſons with diſtorted limbs. Venel has contrived a machine to embrace the patient's limbs when in bed, and which is conſtructed ſo as to act without diſturbing their reſt. This contrivance, it is ſaid, has performed many cures; 5 miles S.W. of Yverdun.—Alſo, a town of Germany, celebrated for its ſalt-works; 26 miles E. of Frankfort on the Maine.

ORBEC, a town of France, in the department of the Calvados, and chief place of a canton, in the diſtrict of Liſieux; 10 miles S.E. of Liſieux. The place contains 3600, and the canton 15,047 inhabitants, on a territory of 180 kiliometres, in 27 communes.

ORBICULAR Leaf, in *Botany*. See Leaf.

ORBICULARIS, in *Anatomy*, an epithet applied to the muſcles which ſurround the openings of ſome organs; as the orbicularis oris or labiorum at the mouth. See Deglutition, and Eye.

Orbicularis, in *Botany*, a name given by ſome authors to the artanita, or cyclamen, called in Engliſh ſow-bread. See Cyclamen.

ORBICULUS Ciliaris, in *Anatomy*, a circular adheſion between the choroid coat and ſclerotica of the eye. See Eye.

ORBIEU, in *Geography*, a river of France, which riſes in the department of the Eaſtern Pyrenées, and runs into the Aude, 5 miles N.W. of Narbonne.

ORBIGA, a river of Spain, which runs into the Duero, near Zamora, anciently called "Urbicus."

ORBION, a lake of the iſland of Corſica, near the ſea, on the E. coaſt; 27 miles S.E. of Corte.

ORBIS, in *Ichthyology*, a ſpecies of *Chætodon*; which ſee.—Alſo, a name given to ſeveral ſpecies of *Diodon*; which ſee.

ORBIT, Orbita, in *Aſtronomy*, the path of a planet or comet; or, the line deſcribed by its centre in its proper motion in the heavens.

The ſun's, or rather the earth's orbit, is the curve which it paſſes along in its annual revolution; called the *ecliptic*.

The orbit of the earth, and that of all the primary planets, is an ellipſis, in one of whoſe foci the ſun is placed; in which ellipſis they move according to this law, that a radius drawn from the centre of the ſun to the centre of the planet, always deſcribes areas proportional to the times.

The ancient aſtronomers made the planets deſcribe circular orbits with an uniform velocity; Copernicus himſelf could not believe they ſhould do otherwiſe. "Fieri nequit," ſays he, "ut cœleſte corpus ſimplex uno orbe inæqualiter moveatur." So that, to account for their inequalities, they were obliged to have recourſe to eccentrics and epicycles; from the embarraſſment of which Copernicus could not entirely diſentangle himſelf.

But after him came aſtronomers, who, with a little more phyſics, have made no difficulty of changing theſe circular orbits into elliptical ones: and of making them move with different velocities in different parts of theſe orbits.

Of theſe elliptic orbits, there have been two kinds aſſigned; the firſt that of Kepler, which is the common ellipſis; to which Seth Ward, though he himſelf keeps to it, thinks one might venture to ſubſtitute circular orbits, by uſing two points, taken at equal diſtances from the centre, on one of the diameters, as they do in the foci of the ellipſis. The ſecond is that of M. Caſſini, whoſe character is this; that the products of the right lines, drawn from each point of its circumference, are every where equal; whereas, in the common ellipſis, it is the ſum of thoſe right lines that is always the ſame. M. Varignon ſhews how inconſiſtent Copernicus's ſentiment is with the mechaniſm of the heavens: ſince the forces which planets have, to retain them in their orbits, muſt almoſt always conſpire to make them move with really different velocities: and that, among an infinity of caſes, there is but one in which they can move uniformly.

The ſemidiameter of the earth's orbit is now ſtated to be 94,696,969 miles Engliſh, and the ſemidiameter of Saturn's orbit about ten times as great.

The orbits of the planets are not all in the ſame plane as the ecliptic, or the earth's orbit round the ſun; but are variouſly inclined to it, and to one another: but ſtill the plane of the ecliptic interſects the plane of the orbit of every planet in a right line, which paſſes through the ſun. See Planet.

The orbits of comets Caſſini takes to be rectilinear; but they are now known to be very eccentric ellipſes. See Comet.

ORBITARIA Foramina, in *Anatomy*, two ſmall holes on the inner ſide of the orbit. See Cranium.

ORBITELLO, in *Geography*, a town of the Sienneſe, but belonging to Naples; ſituated on the E. ſide of a lake, near the coaſt of the Mediterranean, with a good harbour, and well fortified; 65 miles N.W. of Rome. N. lat. 42° 31′. E. long. 11° 6′.

ORBONA, in *Mythology*, a goddeſs worſhipped at Rome, who was invoked in behalf of orphans, or to comfort fathers and mothers for the loſs of their children.

ORBOZ, in *Geography*, a town of Great Bucharia, on the Bamian; 15 miles S. of Balk.

ORBY, a town of Sweden, in Weſt Gothland; 28 miles E.S.E. of Gotheborg.

ORCHAMPS, a town of France, in the department of the Jura; 9 miles W. of Quingey.

Orchamps *en Vennes*, a town of France, in the department of the Doubs; 15 miles E. of Ornans.

ORCHAN, in *Biography*, ſon of Othman, the founder of the Ottoman dynaſty, diſtinguiſhed for his valour, reduced,

duced, during the reign of his father, the important city of Pruſa, or Burſa, the capital of Bithynia. On the death of Othman, in 1326, Orchan was declared his ſucceſſor on the Turkiſh throne. "From the conqueſt of Pruſa," ſays the hiſtorian, "we may date the true era of the Ottoman empire. The lives and poſſeſſions of the Chriſtian ſubjects were redeemed by a ranſom of thirty thouſand crowns of gold; and the city, by the labours of Orchan, aſſumed the aſpect of a Mahometan capital. Pruſa was decorated by a moſque, a college, and an hoſpital of royal foundation; the Seljukian coin was changed for the name and impreſſion of the new dynaſty; and the moſt ſkilful profeſſors of human and divine knowledge, attracted the Perſian and Arabian ſtudents from the ancient ſchools of Oriental learning. Orchan nominated his brother Aladin for his vizier, and he next introduced great improvement into his army. In the ſecond year of his reign he took the city of Nicomedia, by means of a newly invented train of battering engines: and ſoon after made himſelf, by the ſame means, maſter of Nice. Orchan granted a ſafe-conduct to all who were deſirous of departing with their families and effects, but the widows of thoſe who were ſlain in defending their cities, were given in marriage to the conquerors, and the ſacrilegious plunder was ſold and ranſomed at Conſtantinople. Orchan ſubdued the whole province or kingdom of Bithynia, as far as the ſhores of the Boſphorus and Helleſpont; and the Chriſtians confeſſed the juſtice and clemency of a reign which claimed the voluntary attachment of the Turks of Aſia. Yet Orchan was content with the modeſt title of emir, and in the liſt of his compeers, the princes of Roum or Anatolia: his military forces were ſurpaſſed by the emirs of Ghermian and Caramania, each of whom could bring into the field an army of 40,000 men." Orchan having formed an alliance with John Cantacuzenus, great domeſtic of the Conſtantinopolitan court, and afterwards emperor, he adopted his intereſt in the civil diſſentions of that capital, and at length demanded one of his daughters in marriage. Notwithſtanding the difference of religion and manners, the circumſtances of the empire did not permit a refuſal, and Theodora was given to Orchan with great ſolemnity. After the reſignation of Cantacuzenus, the bands of alliance between the Greek and Turkiſh emperors being diſſolved, Solyman, ſon of Orchan, openly invaded Thrace, and made himſelf maſter of Gallipoli, the key of the Helleſpont. The young man was ſoon after killed by accident, while exerciſing his troops, and Orchan was ſo much affected by the loſs of his ſon, that he ſoon followed him to the grave. This event happened in the year 1360, when he was about ſeventy years of age. The piety and juſtice of this prince are greatly extolled by Turkiſh hiſtorians. They ſay that he daily converſed with the learned, and would undertake nothing of moment without their advice and ſanction: and he was the firſt of their monarchs who founded ſchools and hoſpitals. He certainly deſerves to be regarded as one of the principal founders of the Ottoman greatneſs. Univer. Hiſt. Gibbon, vol. xi.

ORCHARD, in *Gardening*, a portion of garden ground ſet apart for the growth of the different ſorts of the more common kinds of fruit, but chiefly that of the apple kind. The trees in this caſe are moſtly of the ſtandard kind, eſpecially when large ſupplies of fruit are wanted, and generally conſiſt of apple-trees, pear-trees, plum-trees, and cherry-trees; and, to render the orchard more complete, it ſhould contain quinces, medlars, mulberries, ſervice-trees, filberts, Spaniſh nuts, and barberries, as well as walnuts and cheſnuts. As the two laſt ſorts are well adapted for ſheltering the others from high winds, they ſhould, Mr. Forſyth thinks, be planted in the boundaries of the orchard, a little cloſer than ordinary for that purpoſe.

In providing trees, eſpecially of the apple kind, for this purpoſe, too much care cannot be taken to admit of none but ſuch as have good roots, fair clean ſtems, and proper heads; and at the ſame time attention ſhould be paid that a proper aſſortment of the different ſorts be procured for the ſupply of the table during the whole year. A few of the ſummer ſorts are ſufficient, but more of the autumn, and ſtill a larger quantity of the winter kind will be neceſſary; as upon this laſt ſort the chief dependence muſt be placed, from the beginning of the year till nearly the period of the fruit being ready again.

In diſtricts where the proceſs of cider-making is conducted upon a large ſcale, large orchards of apples only are often met with; and in ſome counties, as Kent, there are orchards wholly of cherries, or of theſe and filberts. In general, however, there ought to be a much larger proportion of apples than of any other fruit in orchards, as in proper ſituations they are very profitable; and, in addition, the trees have a delightful appearance when in bloſſom, as well as when the fruit is ripe.

Situation and Soil.—In reſpect to ſituation, an orchard ſhould rather be elevated than low, as on a gentle declivity, open to the ſouth and ſouth-eaſt, to give free admiſſion to the air and rays of the ſun, as well as dry up the damps and diſperſe the fogs, in order to render the trees healthy, and give a fine flavour to the fruit. It ſhould likewiſe be well ſheltered from the eaſt, north, and weſterly winds, by ſuitable plantations, where not naturally ſheltered by hills or riſing grounds. Such plantations, when they conſiſt of foreſt-trees, ſhould neither be too large nor too near the orchard; as where that is the caſe, they prevent a free circulation of air, which is injurious to the trees. Where the ground does not admit of ſuch plantations, Mr. Forſyth adviſes planting croſs rows of fruit-trees, in the manner directed in gardens, as well as ſome of the largeſt growing trees, neareſt the outſides expoſed to thoſe winds, two or three rows of which ſhould be planted cloſer than ordinary, which would greatly ſhelter thoſe in the interior parts of the orchard, and be of great ſervice, in addition to the walnut and cheſnut trees, as mentioned above.

Orchards are planted on many different ſorts of ſoil, and ſucceed well; but a dry, friable loam is probably the moſt ſuitable, as trees of this ſort are impatient of moiſture. Such as have been mentioned for gardens will anſwer perfectly well, and ſuch as produce good crops of corn, graſs, or other vegetables, are moſtly proper for an orchard; and though the above ſort is to be preferred, that of a good quality, not too light or dry, nor wet, heavy, or ſtubborn, but of a moderately ſoft and pliant quality, will be found to anſwer the end perfectly. The ſhingly and gravelly ſoils diſagree very much with fruit-trees, unleſs there be loam intermixed with them. They ſucceed much better on a chalk bottom, or ſubſoil. On ſuch a ſoil Mr. Forſyth has ſeen roots twelve feet deep, and the trees thrive well. Where the bottom is clay, the roots ſhould be cut-in once in four years, to prevent them from penetrating the clay, which would greatly injure the trees. Whatever the nature of the ſoil may be, it ſhould have a good depth, as two or three feet. Where the ſoils are wet, they ſhould be well drained, in the ſame manner as directed for gardens; or by forming the land in ridges, with furrows between the rows to convey off the moiſture, the turf being re-laid in caſe of the ground being in the ſtate of ſward.

Form and Size.—In regard to the ſize of an orchard, it may vary from one to ten and fifteen or more acres, according

ing to the quantity of fruit wanted, or the proportion of ground that is fit for the purpoſe. The beſt form is that of the ſquare where it can be had, but other forms anſwer very well.

Preparation.—This is effected in different ways; but the beſt method is, probably, before planting the trees, to trench it two ſpits deep, and ten feet broad, where the rows are to be planted, and to looſen a ſpit below, unleſs it be clay, which ſhould, Mr. Forſyth ſays, be trodden down. Where the ground is in paſture, it ſhould be ploughed, and well ſummer-fallowed, till the graſs be killed, otherwiſe when it is laid in the bottom in trenching, which it generally is, it will be very apt to breed grubs, which do much miſchief. In bad ſhingly or gravelly ſoils, he recommends that holes ſhould be dug at leaſt three feet deep, and filled up with good mould: if mixed up with rotten dung, rotten leaves, or other manure, the trees will in time amply repay the expence: the dung uſed for this purpoſe ſhould be that from the melon and cucumber beds, mixed with the mould from the ſame, when the beds are broken up in autumn, or winter; and be laid up in heaps, and continued ſo for one year at leaſt; but be frequently turned, and have ſome good freſh mould mixed with it. It is the practice with ſome to only dig holes large enough to receive the roots, eſpecially in graſs-ground, which is to be continued ſo. Others prepare the ground by deep ploughing, if the orchard is to be of great extent. The ſward, if paſture, ſhould be ploughed in ſome time in ſpring; a good ſummer-fallow ſhould be given it, ploughing it two or three times, which will rot the turf. A fortnight or three weeks before planting, it ſhould have a good deep ploughing, to prepare it for the reception of the trees. In Kent, and ſome other hop diſtricts, they prepare their orchard-ground, by the growth of hops upon it with the fruit-trees, by which they are much protected and brought forward.

Seaſon of Planting.—In relation to the period of planting, it may be performed with ſucceſs at different ſeaſons, according to the nature of the land. The beſt time for planting on a dry ſoil is, Mr. Forſyth ſays, in October; but, if wet, the latter end of February, or the month of March, will be a more fit ſeaſon. The chief circumſtances in this buſineſs is to ſuit the trees as much as poſſible to the ſoil, and to plant them at proper diſtances from each other; which may be from forty to eighty feet, according to the ſize of the trees when full grown. He obſerves that fruit-trees, when planted too thick, are very liable to blights, and to be covered with moſs, which robs them of a great part of their nouriſhment, beſides ſpoiling the flavour of the fruit. The diſtance ſhould be regulated by the nature of the orchard in a great degree.

Procuring the Trees.—In providing the trees, it is a good practice to procure them from a ſoil nearly ſimilar to, or rather worſe than, that where they are intended to be planted; as trees tranſplanted from a rich ſoil to a poorer one never thrive ſo well; but if from a poor to a richer ſoil, they generally ſucceed in a perfect manner. Good trees, which have been properly pruned, which are quite free from bruiſes and diſeaſe, ſhould always be carefully ſelected; and their roots be preſerved as much as poſſible when taken up.

The moſt proper ſorts of trees for ſmall orchards may be thoſe of the janeting, golden pippin, noneſuch, Ribſton pippin, nonpareil, queen, ſky-houſe, golden rennet, aromatic pippin, grey Leadington, ſcarlet pearmain, lemon pippin, pommegriſe, French crab, ruſſeting, and codling kinds. But various other ſorts may be employed where the orchards are extenſive, and a great variety of fruit neceſſary.

Planting the Trees.—With regard to the proper diſtance of planting the trees, it ſhould be regulated by the natural growth or ſpreading of them when fully grown, as well as the nature and goodneſs of the ſoil. It was formerly the practice to have them put in at narrow diſtances; but at preſent ten, twelve, or fifteen yards are more common, and in the cider diſtricts from twenty to twenty-five yards are in uſe. The uſual mode of arranging the trees is, in open grounds in lines or rows; but in cloſe plantations the quincunx method is more in uſe. In the row method, when it can be done, they ſhould be in the direction of north and ſouth, or one point more to the eaſt, as by this means they will have the advantage of the ſun from the early part of the morning, in the ſpring ſeaſon, which will in a great meaſure prevent the damp fogs from hanging upon them, and hindering the due increaſe of the fruit.

In the act of planting or putting them into the ground, great care ſhould be taken that they are not put in to too great a depth, as where that is the caſe they are in great danger of being deſtroyed. It is alſo neceſſary that a bed of fine good mould be provided for them, and that it be carefully put in with them, ſo as to be properly inſinuated among the fibres of the roots, and afford them due ſupport; the whole being carefully trodden round the plants in finiſhing the buſineſs. Upon this being performed in a proper and perfect manner, and the young trees afterwards kept perfectly ſteady by ſuitable ſupports, the ſucceſs of the planter in a great meaſure depends.

Where the trees are planted in the quincunx order, and at the diſtance of eighty feet, Mr. Forſyth ſays, the ground between the rows may be ploughed and ſown with wheat, turnips, &c. or planted with potatoes: the ploughing or digging the ground, provided it be not done ſo deep as to hurt the roots, by admitting the ſun and rain to meliorate the ground, will keep the trees in a healthy flouriſhing ſtate. It will be neceſſary to ſupport the young trees by tying them to ſtakes until they are well rooted, to prevent their being looſened or blown down by the wind.

In the ſpring, after planting, if it prove dry, ſome turf ſhould be dug and laid round the ſtems of the young trees, with the graſſy ſide downwards; which will keep the ground moiſt, and ſave a deal of watering: if the trees have taken well, this need not be repeated, as they will be out of danger the firſt year. The turf ſhould be laid as far as the roots of the trees are ſuppoſed to extend; and when it is rotted, it ſhould be dug in, which will be of great ſervice to their roots.

Such trees as are of very different ſizes when full grown, ſhould not be planted promiſcuouſly; but, if the ſoil be properly adapted, the larger planted in the back parts or higher grounds, or at the north end of the rows, if they run nearly north and ſouth, and the others in ſucceſſion, according to their ſize. The trees, when planted in this manner, will have a fine effect when grown up; but if they are planted promiſcuouſly, they will not appear ſo agreeable to the eye; and, beſides, the ſmaller trees will be ſhaded by the larger, which injures them, and ſpoils the flavour of the fruit.

It is adviſed that orchards ſhould be dunged once in two or three years with ſome ſort of good manure, as this is of much advantage in rendering them fruitful and productive.

The ſtems of the trees in thoſe where cattle feed, ſhould be high enough to prevent their eating the lower branches; and fenced in ſuch a manner as to prevent their being barked, or injured by the cattle rubbing againſt them, particularly when young; which may be done by triangles of wood, or the trees may be buſhed with thorns.

But in orchards where cattle are not permitted to go, Mr.

Forſyth prefers dwarf-trees to ſtandards, taking care to proportion the diſtance of the rows to the ſize of the trees.

Management afterwards.—This chiefly conſiſts in keeping the trees properly pruned and cut in; as where this is judiciouſly done, the trees will come into bearing ſooner, and continue in vigour for nearly double the common time. But with theſe ſtandard-trees leſs culture is neceſſary than in other caſes. No branch ſhould ever be ſhortened unleſs for the figure of the tree, and then it ſhould be taken off cloſe at the ſeparation. The more the range of branches ſhoot circularly, a little inclining upwards, the more equally will the ſap be diſtributed, and the better the tree bear. The ranges of branches ſhould not be too near each other, that the fruit and leaves may not be deprived of their full ſhare of ſun; and where it ſuits, the middle of the tree ſhould be ſo free from wood, that no branch may croſs another, but all their extremities point outwards.

About October or November, or as ſoon as the fruit is removed, is the moſt proper ſeaſon for this work. It is the beſt practice to take off ſuperfluous branches with a ſaw, and afterwards to ſmooth the place with a knife; for it is eſſential that every branch that is to come off ſhould be cut perfectly cloſe and ſmooth. The wounded part may then be ſmeared over with a proper compoſition. Such branches ſhould always be taken off as come near to the ground, that have received any material injury, where the leaves are much curled, or that have a tendency to croſs the tree, or run inwards. And a little attention may be given to the beauty of the head, leaving all the branches as nearly equidiſtant as poſſible. Where there are any remaining blotches, they ſhould be opened or ſcored with a knife; and where the bark is ragged from any laceration, it ſhould be pared gently down to the live wood: touching over each with a proper compoſition. This being done, the moſs ſhould be rubbed clean off, and the trees ſcored. In this laſt operation, care ſhould be taken not to cut through the inner or white rind, which joins the bark to the wood. When trees are much thinned, they are ſubject to throw out a great quantity of young ſhoots in the ſpring, which ſhould be rubbed off, and not cut, as cutting is apt to increaſe the number.

The great enemy to orchards where apples is grown, is miſletoe, and it is often permitted to become very injurious to them. The uſual method of clearing trees from it, is to pull it out with hooks in froſty weather, when brittle, and readily broken off from the branches. A labourer is capable of clearing fifty or ſixty trees in a day.

Moſs, moiſt ſpring froſts, blights, and ſeveral other ſimilar cauſes, are highly injurious to this ſort of tree, as is ſhewn under theſe particular heads.

ORCHARDS, in *Huſbandry*, ſuch as are formed in fields for the purpoſe of affording the liquor called cider. Theſe orchards are very extenſive in many diſtricts, and form the chief part of the produce of the countries where they exiſt. The manner of forming them is ſtated above. There are a great many varieties of apples and pears made uſe of in theſe orchards.

It is remarked in the Herefordſhire Report on Agriculture, that the apple and pear-trees which form the orchards of that diſtrict, are well known not to be the natural production of any ſoil or climate, the one being a variety of the *pyrus malus*, or crab, and the other derived from the *pyrus communis*, or common wild pear; as ſuch, neither of them are noticed by Linnæus. The native wild crab is ſubject to conſiderable diverſity in the appearance of its leaves, and in the colour, ſhape, and flavour of its fruit.

By ſelecting and cultivating the beſt of theſe, all our valuable varieties have been produced, and by repeated propagation have been preſerved for the time. This principle was, it is ſaid, clearly known by the ancients, whether they applied it to the apple or not; as is evident from Virgil. And it is added that Normandy, and other parts of the continent, have occaſionally furniſhed this country with ſeveral of theſe artificial varieties. It is likewiſe ſtated, that the apple-trees are divided into *old* and *new* ſorts; each claſs compriſes ſome called *kernel* fruits, namely, the fruit growing on its native root, as a diſtinction from thoſe produced by the operation of grafting.

The old ſorts are the more valuable, and are thoſe which have been long introduced, ſuch as the ſtire, golden pippin, hagloe crab, ſeveral varieties of the harvey, the brandy apple, red ſtreak, woodcock, moyle, gennet moyle, red, white, and yellow muſks, pauſon, fox-whelp, loan and old pearmains, Dymock red, ten commandments, and others. Some of theſe names are deſcriptive of the fruit, and others are derived from the places where they have been firſt found, or found in moſt abundance. The modern varieties derive their appellations from ſuch various and capricious cauſes, that a correct liſt cannot be compoſed; in ſeveral inſtances, the ſame fruit bears a different name, even in the ſame pariſh. A regular and ſcientific claſſification of the whole would be, it is ſuppoſed, a valuable acquiſition to our rural economy, and there are at this time perſons of opulence and public ſpirit fully adequate to ſuch an undertaking.

The pears held in moſt eſtimation, are the ſquaſh, ſo called from the tenderneſs of its pulp; the old-field, from having grown as a ſeedling in a field of that name: the huff-cap, from the quantity of fixed air contained in its liquor; the bar-land, from fields in the pariſh of Boſbury, called the Barlands, which were anciently held under the tenure of conveying the proviſion of the lord, or Barelands, from their deficiency of produce at ſome particular period; the ſack pear, from its richneſs; and the red pear, from its colour.

Of the more common ſorts, the long-land is the moſt valuable, and, for the general uſe of the farmer, perhaps the beſt of any. See APPLE, APPLE-*tree*, and CIDER.

In regard to the cider fruits, it has been remarked, that as the decay of the old and moſt valuable fruits in Herefordſhire is ſo generally acknowledged and lamented, their renovation, or the introduction of others equally good, cannot be too ſtrongly urged; and that the public ſpirit of the preſent age has not been indifferent on the occaſion, as more endeavours have perhaps been directed towards this object within the laſt twenty years, than during a century preceding. Grafting, as moſt expeditious, has been moſt frequently attempted; but it is preſumed that no mode of grafting hitherto practiſed has been found adequate to the purpoſe. The ſhoots, being unavoidably taken from old trees, flouriſh during a few years from the vigour of the crab ſtock, and relapſe into all the infirmities of the parent tree. On this principle, the renovation of the old fruits appears impracticable. By the general laws of nature, each animated being lives to propagate its ſpecies, and after a time reſigns its place to a ſucceſſor. Mr. Knight obſerves, that the branch, from which a graft is taken, evidently partakes of the life of the tree to which it belongs; and that it is equally evident, that when part of a tree is detached, no new life is communicated, whether it be uſed as a graft, or placed to emit roots as a cutting: thus a tree, raiſed from a cutting, ſoon produces fruit in every reſpect ſimilar to that of the tree from which it was taken. He

alſo

alſo remarks, that the habits of ſeedling trees are very eſſentially different, that their leaves are ſmall and thin, and that the general habit changes gradually, aſſuming annually a more cultivated character: thus, if a graft be taken from a ſeedling tree of one or two years old, it will retain the character, and undergo the ſame annual change as the ſeedling tree, whatever be the age of the ſtock into which it is inſerted; and that it will remain unproductive of fruit or bloſſom, until the ſeedling tree has acquired its proper age and maturity.

Hence he infers, as before mentioned, that the cutting muſt partake of the life, and conſequently of all the habits of the original tree. In ſupport of this theory, he ſtates that a ſeedling walnut, grafted with a part of the bearing branch of an old tree, produced bloſſom at three years old; that the Spaniſh cheſnut, under a ſimilar proceſs, bloſſomed in the year after it was grafted; and that an annual ſcion of a mulberry-tree, thus grafted, bore a plentiful crop of fruit (conſidering its ſize) in the third year after, and has continued to bear every year ſince. The grafts in theſe caſes, Mr. Knight remarks, muſt have carried the nature and habits of the parent tree with them; and if they retain the habits, it may fairly be inferred that they retain alſo the ſame progreſſive tendency to decay. In ſhort, a tree, like an animal, has "its infancy, its flowering ſpring, its ſummer's ardent ſtrength, its ſober autumn fading into age, and its pale concluding winter."

The opinion of the beſt informed planters is, that the ſeeds of the old fruits ſhould be ſown, and the moſt ſtrong and healthy plants ſelected for cultivation, and a ſupply of grafts. This experiment has been adopted on a large ſcale by ſeveral planters, has hitherto promiſed the fulleſt ſucceſs, and has, further, the ſanction of that period in which orcharding received particular attention. And it is added, that a treatiſe on this ſubject was publiſhed by W. Lawſon, a north countryman, in the year 1626; and he ſtates, that the very beſt way to plant an orchard is to turn the ground with a ſpade in February, and to ſet, from February to May, ſome kernels of the beſt and ſoundeſt apples and pears a finger deep, and a foot diſtance; and to leave the likelieſt plants only in the natural place, removing the others as time and occaſion ſhall require. And that lord Scudamore alſo fully underſtood the nature and value of this practice; who, on retiring to Horn Lacy, amidſt other uſeful and honourable employments of a country life, paid great attention to the culture of fruit-trees, and particularly to that of the red ſtreak, which he ſeems to have introduced into general notice and eſteem. As late alſo as the year 1654, a treatiſe, called "The Countryman's Recreation, or the Art of Planting, Grafting, &c." remarks, that "although the pippins be ſown of the pomes of pears and good apples, yet we ſhall find that ſome of them do love the tree whereof they came, and thoſe be right which have a ſmooth bark, and are as fair as thoſe which be grafted." Theſe inſtances, it is preſumed, are ſufficient to ſhew that, at the period alluded to, it was well known, that good fruits might be raiſed by ſowing the kernels of good apples, and ſelecting thoſe plants, which, in the abſence of thorns, and in the general appearance of their leaves and bark, bore the greateſt reſemblance to the cultivated variety of the parent tree; whilſt thoſe which approach the native crab were carefully rejected.

Yet Evelyn, in the Appendix to his Sylva, publiſhed ſeveral years afterwards, proves that the practice was hardly known there in his time. He writes, nothing is more facile than to raiſe new kinds of apples *in infinitum* from kernels; yet in that apple county (Hereford), ſo much addicted to orchards, we could never encounter more than two or three perſons that did believe it. This method, however, is now becoming more and more general. The writer ſays, ſeveral thouſand grafts, thus raiſed, are yearly diſtributed by the Agricultural Society, and are ſought for with the utmoſt avidity. The moſt experienced planters conſider it as the beſt, if not the only, expedient to preſerve their provincial celebrity; and nothing ſurely can be more unphiloſophical than to ſuppoſe that a piece of old dying tree can ever form a healthy and vigorous one.

It is added, that Mr. Knight has now many ſeedling apple-trees, produced between the Siberian crab and our richeſt apples. The vigour of moſt of them is aſtoniſhing. And as they bloſſom as early as the pear-trees, he is convinced that they will be found of great value, particularly in high ſituations, where the Siberian very rarely fails to produce a good crop of fruit.

In reſpect to the management afterwards, it chiefly conſiſts in keeping the trees properly pruned, thinned, and cut in as above. In Herefordſhire, large branches are rarely or never amputated. The inſtrument generally uſed for the purpoſe of pruning is a ſtrong flat chiſſel, fixed to a handle ſix feet or more in length, having a ſharp edge on one of its ſides, and a hook upon the other.

It has been ſtated by the author of the Treatiſe on Fruit-trees, that when young trees are planted out from the nurſery, as ſoon as they begin to break in the ſpring, they are to be cut down to three or four eyes, according to their ſtrength, to furniſh them with bearing wood. If this were not done, they would run up in long naked branches, and would not produce one quarter of the fruit which they do when this operation is properly performed. The ſame holds good in healing all kinds of old trees.

An opinion prevails, particularly in thoſe parts where apple-trees are cultivated to any conſiderable extent, that trees never will bear after being headed down, and that it kills them. This may no doubt happen when they are improperly headed down all at once, by giving a ſudden check to the ſap, the few weak ſhoots not having ſtrength to draw up what is ſupplied by the roots; and, moreover, not being capable of ſheltering one another, they are chilled by the cold, and ſo rendered at leaſt unproductive, if they are not totally killed. But if heading were done gradually, that is, if every other branch all over the tree were headed at a proper length, cutting as near to thoſe parts where the ſhoots appear as poſſible, in the months of February or March, or even as late as May, in the courſe of the ſummer they would throw out fine long ſhoots. Theſe ſhould not be ſhortened the firſt year, unleſs it be neceſſary to ſhorten a few, to fill up the head of the tree with bearing wood; and that ſhould be done in the following ſpring, cutting them to ſix or eight inches long, according to their ſtrength. In the next ſpring, after the firſt branches are headed, the remaining old branches may be cut out, and theſe will ſoon fill the head of the tree with fine bearing wood. In three years, if properly managed, trees ſo headed will produce a much greater quantity of fruit, and of a better quality, than they did before the operation was performed. It has been remarked, that the management of orchards is capable of being reduced to a ſyſtem under a few general heads, concentered in the principle of making all trees in orchards healthy, round, large, and beautiful.

Due pruning would greatly prevent the ſpeckled and ſtunted fruit, occaſioned by the trees being overloaded with wood, which obſtructs the rays of the ſun, and cauſes a vapour, the cold whereof ſtunts the fruit in its firſt growth. When branches of any great ſize are to be cut off, Mr. Bucknall found it impoſſible to take them off by a bill,

without leaving a ſtump, or improper wound: and as it is eſſential that every branch be cut perfectly cloſe and ſmooth, he uſed ſaws, and afterwards ſmoothed over the ſaw-cut with a knife, immediately applying his medicated tar to the wound. The medicated tar is compoſed of half an ounce of corroſive ſublimate, reduced to a fine powder, and put into a three-pint pipkin, with a glaſsful of ſpirits of hartſhorn, and ſtirred well together till the ſublimate is diſſolved. The pipkin is then filled by degrees with common tar, and conſtantly ſtirred till the mixture is blended as intimately as poſſible. This compoſition has been found by Mr. Bucknall to anſwer the purpoſes of excluding the air, keeping off inſects and vermin of every deſcription, and of aſſiſting the wound to heal. But the compoſition directed by Mr. Forſyth is probably much better.

In heading down old decayed apple-trees, for the ſake of ſymmetry, the author of the Treatiſe on Fruit-trees ſays, it will be neceſſary to cut at the forked branches, as near as can be to the upper ſide of the fork, cutting them in a ſloping manner, to carry off the wet, at the ſame time rounding the edges. The orchardiſt may begin at the lower branches, cutting juſt above the lower bark, and proceeding upwards, cut the reſt of the branches to ſix joints or forks, according to their ſtrength, till he have finiſhed cutting in the whole head. If any of theſe branches ſhould have the canker, all the infected part muſt be cut out. When the tree is all prepared, the compoſition muſt be immediately applied, beginning at the top of the tree, and finiſhing with the powder of wood-aſhes and burnt bones in deſcending, which will ſave its being rubbed off during the operation, and the compoſition will prevent the ſun and air from injuring the naked inner bark. A tree thus prepared will, in the courſe of three or four years, produce more and finer fruit than a maiden tree that has been planted upwards of twenty years.

Mr. Marſhall remarks, in his 'Rural Economy of Glouceſterſhire and Herefordſhire,' that ſpring froſts are an enemy, againſt which, perhaps, it is moſt difficult to guard orchard trees. Dry froſts are obſerved to have no other effects than keeping the bloſſoms back; conſequently, are frequently ſerviceable to fruit-trees. But wet froſts, namely, froſts after rain or a foggy air, and before the trees have had time to dry, are very injurious even to the buds. An inſtance is mentioned, in which a flying hazy ſhower in the evening was ſucceeded by a ſmart froſt: that ſide of the trees againſt which the haze drove was entirely cut off; while the oppoſite ſide, which had eſcaped the moiſture, likewiſe eſcaped the effect of the froſt.

Much, however, may depend on the ſtrength of the bloſſoms. The ſpring of the year (1788) had its froſts, and all hope of fruit was more than once given up; yet for quantity and quality, taken jointly, there has ſeldom perhaps been ſo favourable a fruit year. But this year, the buds formed, and the bloſſoms broke forth with unuſual vigour; and were enabled, by their own ſtrength, to ſet common enemies at defiance. On the contrary, the preceding ſpring, many of the bloſſoms ſickened in the bud, and thoſe which opened were weak and languid: the conſequence was, in the inſtances he obſerved, ſcarcely an apple ſucceeded.

The aſſiſtance, therefore, required from art in this caſe, is, by keeping the trees in a healthful vigorous ſtate, to enable them to throw out a ſtrength of bud and bloſſom; and by keeping them thin of wood, to give them an opportunity of drying quickly before the froſt ſets in. See BLIGHT.

The author of the Report for the county of Hereford ſays, that the pear, although, in general, producing an inferior liquor, poſſeſſes many advantages for general culture, when compared with the apple. It will flouriſh in a greater variety of ſoils, is more productive, and being incapable (in thoſe ſorts which are proper for perry) to be eaten or applied to any common culinary purpoſe, it is little ſubject to be ſtolen, even in ſituations where fruit does not abound. As an ornamental tree, it poſſeſſes ſufficient merit to entitle it to a place where ornament is the principal object; its form is often picturеſque, and it bloſſoms in the ſpring, and its fruit in autumn is always beautitul. Every tree, when nearly full grown, will afford, in moderately good ground, an annual produce of twenty gallons of liquor, (taking many years together,) even at the loweſt calculation. Many ſingle trees in Herefordſhire have produced a hogſhead in one ſeaſon, and an extraordinary tree growing on the glebe land of the pariſh of Hom Lacy has more than once filled fifteen hogſheads in the ſame year; when the branches of this tree, in its original ſtate, became long and heavy, their extreme ends ſucceſſively fell to the ground, and taking freſh root at the ſeveral points where they touched it, each branch became a new tree, and in its turn produced others in the ſame way. Nearly half an acre of land remains thus covered at the preſent time. Some of the branches have fallen over the hedge into an adjacent meadow, and little difficulty would be found in extending its progreſs. An acre of land is capable of containing thirty pear-trees of uſual dimenſions, which, taken from new varieties of fruit, would probably continue in a productive ſtate beyond the concluſion of a ſecond century. The produce of an acre planted with apple-trees, will generally be found nearly one-third leſs than the ſame quantity of ground planted with pear-trees would afford, with the exception of the halmer pear, and the old-field; but the apple-tree begins to bear at an earlier age, and cider will ever be juſtly preferred to the juice of the pear. As an object of ſight, the pear-tree has every advantage over its rival; but Mr. A. Knight is of opinion that under the ſyſtem now practiſing, to procure new varieties, the apple-tree may, in ſome degree at leaſt, acquire the recommendation of ornament, as well as uſe; thoſe croſſed with the Siberian crab promiſe to be of this deſcription. The value of the ground as a paſture in cloſely planted orchards will neceſſarily be much reduced, but the loſs of herbage will in a few inſtances amount to more than one-tenth of the value of the fruit.

The graſs produced in an orchard comes very early in the ſpring, when it is peculiarly valuable to the farmer. Under judicious management it is never ſuffered to grow long or coarſe, and an orchard in this condition will be found to ſupport a very conſiderable quantity of ſtock.

It is further obſerved in the ſame report, that if the apple and pear-trees were thinly diſperſed over the meadows and paſtures of every diſtrict in which they would ſucceed, the injury done to the herbage would be extremely ſmall; and the trees might perhaps be made to ſupply the whole population of the country employed in agriculture, with as wholeſome and palatable a beverage as they now poſſeſs, and in fruitful years a large quantity would be afforded for the uſe of the towns. The number of acres now employed in raiſing hops and poles to ſupport them, might be greatly reduced, and this alone would prove an immenſe advantage to agriculture. Hops at preſent occupy the beſt ground the farmer has to give them, they take his beſt manure, they are too often the principal objects of his attention, and whilſt their culture injures the crops of corn in every diſtrict where they abound, it may be queſtioned whether the produce of a thouſand acres annually afford nutriment ſufficient to ſupport a human

a human being. By an extended culture of the apple and pear, many millions of buſhels of barley, now converted into malt, might be annually ſaved and applied to better purpoſes.

The ground now employed in its culture might be made to produce wheat, or other articles immediately neceſſary to ſociety; and that the juice of the apple and pear will afford a liquor as wholeſome as any which can be obtained from malt, is ſufficiently evinced by the general appearance of the natives of this and other cider counties.

In the diſtrict of Kent, according to Mr. Marſhall, in ſome inſtances the interſpaces of young orchards are occupied by hops, in others by filberts, and in grown orchards the latter are ſometimes ſeen. Some old orchards are likewiſe in permanent ſward, others under arable or garden crops, and ſome in ſainfoin, while others are in lucern. See PLANTING, FRUIT-*Trees*, and APPLE-*Tree*.

It has been obſerved by the author of the Rural Economy of Glouceſterſhire and Herefordſhire, that the cultivation of fruit-trees, for the ſole purpoſe of liquor, is peculiar to the weſtern provinces. The ſouthern counties, when the London markets are overſtocked with fruit, make a ſort of liquor from the ſurplus; but the eaſtern, the northern, and the midland counties, may be ſaid to be as much unacquainted with the buſineſs of a liquor-orchard, as they are with that of a vineyard. Even Staffordſhire, which is divided from the cider country by a narrow ridge of hill only, has not, generally ſpeaking, a barrel of cider made within it.

Herefordſhire has ever borne the name of the firſt cider county; Glouceſterſhire, however, claims a preference in the two moſt celebrated fruit-liquors the diſtrict affords. Worceſterſhire and Monmouthſhire have their claims of excellency. May Hill may be conſidered as the centre of this diviſion of the cider country.

Devonſhire, and its environing counties, form another diviſion; which, though upon the whole much inferior to this, produces one ſpecies of liquor (the coccagee cider,) which is in high eſtimation. See CIDER.

Perſons robbing orchards are to make ſuch recompence of damage as a juſtice ſhall award, and forfeit not exceeding 10*s*. or be ſent to the houſe of correction, &c. Stat. 43 Eliz. cap. 7. See LARCENY.

ORCHARD, *Cherry*, in *Agriculture*, that ſort of orchard which is principally deſtined to the raiſing of cherries. Theſe ſorts of orchards are common in the county of Kent, in which the common black cherry is moſtly cultivated, though, according to Mr. Marſhall, it is now on the decline. In Hertfordſhire, about King's Langley and Watford, they employ the caroon and ſmall black, as the Kentiſh will not thrive there at all. In Kent they are planted in lines at the diſtance of twenty feet aſunder, but in Hertfordſhire they allow each tree nine ſquare perches of land. In about two years after planting, cherry-trees begin to bear, and a full-grown tree will produce fifty dozen pounds in a good year, and from ten to twenty years ſix dozen. The prices vary from ten-pence to three ſhillings the dozen. They are very beneficial to the poor in the quantity of employment which they afford in gathering the crop, in which they are paid from 4*d*. to 8*d*. *per* dozen pounds.

ORCHARD-*Fruit*, that ſort of fruit which is grown in orchards. In ſome diſtricts, and particularly that of Kent, beſides apples and pears, they have other ſorts of orchard-fruits, ſuch as plums, cherries, filberts, &c.

ORCHARD-*Graſs*, a ſmall, fine, very ſweet graſs, riſing under the trees in orchards. This ſort of graſs is of a very purgative quality. It ſhould be kept eaten down well, in order to render it the moſt productive.

ORCHESIS, in the *Ancient Pantomime*, was a term given by the Greeks to what the Romans termed *Saltatio*. It conſiſted in imitating all the geſtures, and all the movements practiſed by mankind. Varro tells us that the word *Saltatio* comes from Salus, who firſt taught the art to the Romans. We muſt not, as is generally done, confound the dance with the leap; but remember that the true dance of the ancients was an imitation of the actions, attitudes of the body, geſtures, in ſhort, of all the demonſtrations with which men commonly accompany their ſpeech, or which they ſometimes uſe to explain their ſentiments without the aſſiſtance of words.

The art was divided into many ſpecies, and had produced among the ancients ſuch a number of different dances, that Meurſius compoſed an entire dictionary with their names. According to Athenæus, Theloſtes was the inventor of this kind of dance, which we call the *acting art*.

This was, of all the muſical arts, that of which the ancients were moſt paſſionately fond, and which was of the greateſt utility in every ſtate of life, from the ſtrolling player to the orator.

Apuleius has left us a deſcription of a repreſentation of the Judgment of Paris, executed in pantomime. He only uſes the word *to march*, and ſays, that Venus *declaimed with her eyes*. So that the ancients ſeldom boaſted of feats of activity with the legs and feet of their dancers; but often with their arms and hands. The muſe Polhymnia was the patroneſs of Mimes, with her finger on her mouth in token of ſilence. Some etymologiſts, among whom are Plutarch and Nonnus, derive her name from Μνημη, *tradition*, alluding to the tales and fables of antiquity. Nonnus, Dionyſ. v. v. 104, et ſeq. ſays,

> "Sweet Polhymnia ſee advance,
> Mother of the graceful dance.
> She who taught the ingenious art
> Silent language to impart:
> Signs for ſentiment ſhe found,
> Eloquence without a ſound:
> Hands loquacious ſave her lungs,
> All her limbs are ſpeaking tongues."

See MIME and PANTOMIME.

ORCHESOGRAPHY, the art of noting all the ſteps and motions uſed in dancing. See DANCE.

ORCHESTRA, in the *Drama*, the lower part of the ancient theatre; made in form of a ſemicircle, and ſurrounded by the ſeats.

It was ſo called, becauſe, in the Grecian theatres, it was a place where they held their balls; from ορχεομαι, *I dance*.

The orcheſtra, among the Greeks, made a part of the ſcena; but, on the Roman theatres, none of the actors went down to the orcheſtra, which was taken up with ſeats for the ſenators, magiſtrates, veſtals, and other perſons of diſtinction; anſwering, nearly, to the pit in our theatre.

The orcheſtra of the ancient Greeks had its name from being that part of the theatre where the *dances* were performed. At preſent the word is more particularly applied to the ſtation where a band of muſic is placed in a theatre, or great concert room. The leader of a band, or orcheſtra, ſhould not only be a great and experienced performer, but of a firm and determined character, that commands reſpect for his orders; given without inſolence or tyranny, but in a manner not to be diſputed or diſregarded. All the perfections or defects of an orcheſtra are aſcribed by the public to want of diſcipline or weight in the leader. The numerous

imitative

imitative and pictureſque effects dependant on the orcheſtra of an opera, excite as much attention in the audience, as the poetry and ſinging. The orcheſtra is a compoſer's palette, and each ſolo inſtrument a colour and a pencil. The tone of theſe, whether alone, or in the aggregate, ſhould have their peculiar and general effect, occaſionally, and contribute to the colouring of the piece.

The material of which an orcheſtra is conſtructed, is not a matter of indifference; it ſhould be formed of ſoft and ſonorous wood, ſuch as picked deal or fir; the ſpectators ſhould not be allowed a place ſo near as to lean upon it, and check its vibration. It ſhould be regarded as a grand inſtrument, which accords with all the others, and augments their effects. The arrangement of an opera band ſhould be in ſuch a manner, as that the ſeveral inſtruments may not be too near or too remote from each other. The number of each ſpecies of inſtruments ſhould be proportioned to the effect which they ought to produce when employed together. The baſes, for example, ſhould not ſuffocate the trebles, nor the trebles be overpowered by them. The hautbois ſhould not domineer over the violins, nor the ſeconds over the firſt. The wind-inſtruments and drums, above all, ſhould be kept under, and not fancy that muſic and noiſe are ſynonimous terms. With regard to the diſtribution of the interior, care muſt be taken, firſt, that the violins are ranged in two lines, facing each other, one fronting the ſtage, and the other facing the audience; 2dly, that the baſes ſhould be diſpoſed round the two harpſichords, and in every part of the orcheſtra; as the baſe, which regulates and ſuſtains the harmony of the ſeveral parts, ſhould be equally heard by all; 3dly, that all the performers ſhould have an eye on the maſter at the firſt harpſichord, and the maſter be enabled to ſee them; in the ſame manner each violin ſhould be in ſight of the leader, and each reciprocally ſee and be ſeen by each other.

In 1754, the firſt orcheſtra in Europe for number and intelligence, was that of Naples; but that which was the beſt diſtributed, and formed the moſt complete whole, was the orcheſtra of the king of Poland, at Dreſden, under the direction of the illuſtrious Haſſe; a plate of which is inſerted G fig. 1. in Rouſſeau's Hiſt. de Muſ. The repreſentation of this orcheſtra ſhews how, by a ſingle glance of the eye, an idea may be formed of the diſtribution of the performers, better than by a long verbal deſcription. We aſked ſignor Haſſe at Vienna if this repreſentation of the Dreſden orcheſtra was accurate, and he ſaid it was ſo correct, that he ſhould have imagined that M. Rouſſeau had been an able painter, and made the drawing himſelf.

Rouſſeau finiſhes the article orcheſtra by a contraſted deſcription of that at Paris of the ſame period, which we ſuppoſe has been reformed with the ſtate. It will, however, be hiſtorical, and enable our readers to form ſome idea of what kind that muſic was, and how performed, with which the natives of France were ſo pleaſed and excluſively vain.

"It has been obſerved," ſays the citizen of Geneva, "that of all the orcheſtras in Europe, that of the opera at Paris, though one of the moſt numerous, produced the leaſt effect. The reaſons are very obvious; firſt, the bad conſtruction of the orcheſtra, buried in the earth, and ſurrounded with rails of heavy and maſſy wood, cramped with iron, which impedes all reſonance. 2. The bad choice of the performers, for the moſt part forced on the manager by recommendation, with ſcarce any knowledge of muſic, or the leaſt intelligence or attention to the effect of the enſemble. 3. Their ſtunning and invariable noiſe, tuning, and flouriſhing continually with all their force, without ever being in tune. 4. The French propenſity, which is in general to neglect and diſdain all that becomes a daily labour. 5. The bad inſtruments of the performers, which remaining on the ſpot are always out of order and unfit for uſe, deſtined to roar during one half of the year, and to rot the other. 6. The bad ſituation of the maſter, who is in front of the theatre, and occupied by the vocal performers, is not able to attend ſufficiently to the orcheſtra, which is behind him inſtead of being in full view. 7. The inſupportable noiſe the truncheon of him who beats the time makes, which covers and deſtroys all the effects of the ſymphoniſts. 8. The bad harmony of the compoſitions, which being never pure and ſelect, lets nothing be heard but noiſe and confuſion. 9. The ſcarcity of double baſes and violoncellos, of which the drawling ſounds ſuffocate the melody and deafens the audience. 10. And finally, the total want of meaſure, and indeterminate character of the French muſic, where it is the ſinger who directs the orcheſtra, inſtead of the orcheſtra regulating the ſinger, and where the treble leads the baſe, inſtead of the baſe leading the treble."

Sixteen years after this period, the orcheſtra at Bruſſels was the moſt celebrated in Europe, though its performers were the miniſters of French muſic. It was under the direction of M. Fitzthumb, a very active and intelligent maeſtro di capella, who beat the time (which then could not be diſpenſed with), and was indefatigable in preſerving good diſcipline. The orcheſtra was ſo admirably conducted, and the band, taken as a whole, ſo numerous, powerful, correct, and attentive, that if the horns had not been bad and out of tune, the effect of the whole would have approached perfection ſo near as to have tongue-tied criticiſm itſelf.

ORCHIDEÆ, in *Botany*, a moſt natural and very curious order of plants, which has attracted general notice by its beauty and ſingularity, derives its name from one of the principal genera of which it is compoſed, and makes the ſeventh among the natural orders of Linnæus, the third of the fourth claſs in Juſſieu. For the characters of this fourth claſs, ſee MUSÆ.

Great advances have been made in the knowledge of theſe plants ſince the publications of Linnæus and Juſſieu, whoſe remarks we ſhall therefore paſs over. Swartz, purſuing a path which Haller had in ſome meaſure pointed out, undertook a new arrangement of the *Orchideæ*, chiefly depending on the ſtructure of their anthers. He has publiſhed his ſyſtem in the Upſal and Stockholm Tranſactions, and laſtly, in a more perfect form, in the firſt volume of Schrader's New Journal. Willdenow in his Sp. Pl. v. 4, follows the ſteps of Swartz. We have had frequent occaſion to refer to theſe writers, under genera belonging to the order in queſtion; ſee CYMBIDIUM, DENDROBIUM, DISA, EPIDENDRUM, EPIPACTIS, &c. Mr. Brown, in his Prodr. Fl. Nov. Holl. v. 1. 309, has reviſed the labours of his predeceſſors, corrected ſeveral miſtakes, and thrown much new light on the ſubject, for which the novel productions of New Holland have in this, as in other caſes, afforded him ample opportunity. We ſhall give a ſketch of the characters of the *Orchideæ*, founded chiefly upon his principles, except that we preſume to conſider as a calyx the three outer leaves or ſegments only of the flower, and the two innermoſt, with the lip, or nectary, as corolla. Swartz takes the five leaves for a calyx, the lip only for the corolla.

Cal. Perianth ſuperior, permanent, of three leaves, either diſtinct, or more or leſs united at their baſe; the dorſal or uppermoſt often broadeſt and moſt concave, rarely elongated below into a pouch or ſpur; all frequently coloured. *Cor.* Petals two, equal, between the dorſal and lateral leaves of the calyx, and of a ſmaller ſize; their baſe ſometimes elongated into a pouch with that of the lateral calyx-leaves.

Nectary

Nectary a lip, dependent or prominent in front, between the two petals, and inſerted in the ſame row or circle with them, various in ſhape and colour, undivided or lobed, entire or many-cleft, convex or concave, ſometimes bearing honey on its upper ſurface, often continued at the baſe into a bag or ſpur behind the flower, which ſpur contains the honey, and is in ſome few inſtances double. *Stam.* Filaments, according to Mr. Brown, really three, though united more or leſs completely together by means of the ſtyle, or column (as it is technically called) and directed towards the dorſal leaf of the calyx, in oppoſition to the lip; the two lateral or lowermoſt of theſe filaments are, for the moſt part, abortive, and generally obſolete, being perfect, or bearing anthers, in *Cypripedium* only; the third only in general bearing an anther, and being abortive when the lateral ones are perfect; anther of two cells, its lobes either diſtant, in which caſe they are united with the ſides of the column, whoſe ſummit is frequently elongated beyond them, or they are approximated ſo as to compoſe an anther either parallel to the ſtigma and fixed, or terminating the column in the form of a moveable lid; each cell is very commonly divided internally by a longitudinal partition, which in ſome few inſtances is threefold; the pollen coheres in elaſtic maſſes, one of them in each cell, and each frequently attaching itſelf, by an elongated viſcid baſe, to the ſtigma, or indeed to any thing on which it happens to fall from the anther. *Piſt.* Germen roundiſh, obovate, or elliptical, ribbed, with three principal angles oppoſite to the three calyx-leaves, of one cell, with three linear parallel receptacles attached to its valves oppoſite to the petals and lip; ſtyle columnar, bearing the anther or anthers, ſomewhat oblique, ſometimes very ſhort; ſtigma a glandular moiſt and lucid ſpace, generally in front looking towards the lip, convex or concave, furniſhed at the top or at the ſides with one or two glands, which are either naked, or contained in a pouch or ſack, that is ſometimes common to both, ſometimes double and diſtinctly appropriated to each; ſee Ophrys: to theſe glands the maſſes of pollen naturally attach themſelves when the anther opens. *Peric.* Capſule ovate or inclining to cylindrical, of three valves, often burſting by clefts between the three principal ribs, and cohering at the baſe and ſummit. *Seeds* very numerous and minute, each generally encloſed in a membranous tunic, pointed at both ends; but in *Vanilla* they are naked.

The habit of theſe plants is generally herbaceous, ſometimes rather ſhrubby. *Root* tuberous, often globoſe, or fibrous, thick and fleſhy, perennial. *Stem* ſimple, rarely branched, either leafy or ſheathed. *Leaves* ſimple, entire, ſheathing at the baſe, alternate, in the branched ſpecies, (which are often paraſitical,) peculiarly coriaceous and rigid. *Flowers* either ſpiked, racemoſe, corymboſe, or ſolitary, rarely panicled; each attended by a *bractea*. *Pubeſcence*, if preſent, which is not often the caſe, ſimple and acute, ſometimes compoſed of capitate glands. The propagation of theſe plants by the root is, in fact, like that of the potatoe and other tuberous plants properly ſo called. Each knob, of the globoſe and palmate-rooted kinds, flowers but once, and that either the ſeaſon immediately ſubſequent to its formation, or ſeveral years afterwards; it then withers and decays. Meanwhile a knob for the following year is perfected, juſt as the former is flowering. The ſame proceſs appears to take place in ſome *Orchideæ* with bundles of thick fibres, and perhaps even in the paraſitical creeping kinds.

The genera in Linnæus are eight, *Orchis*, *Satyrium*, *Ophrys*, *Serapias*, *Limodorum*, *Arethuſa*, *Cypripedium* and *Epipendrum*; to which Juſſieu adds *Thelymitra* of Forſter, *Diſa* of Bergius, *Bipinnula* of Commerſon, *Vanilla* of Plumier, and a new genus of his own called *Pogonia*. Swartz does not adopt *Bipinnula* nor *Pogonia*, but he has eſtabliſhed ſeveral new and, for the moſt part, very good genera, *Peristylus*, *Diſperis*, *Corycium*, *Neottia*, *Cranichis*, *Epipactis*, *Malaxis*, *Cymbidium*, *Oncidium*, *Aërides*, *Dendrobium*, *Stelis* and *Lepanthes*. Willdenow adopts theſe, along with *Diuris* of Smith, to which he has added two genera of his own, *Bonatea* and *Habenaria*. Swartz has taken up, from the Flora Peruviana, *Anguloa*, *Gongora* and *Maſdevallia*, which Willdenow omits. Brown has the following new genera from New Holland, *Epiblema*, *Orthoceras*, *Cryptoſtylis*, *Praſophyllum*, *Genopleſium*, *Calochilus*, *Microtis*, *Acianthus*, *Cyrtoſtylis*, *Chiloglottis*, *Eriochilus*, *Caladenia*, *Lyperanthus*, *Gloſſodia*, *Pteroſtylis*, *Coryſanthes*, *Caleana*, *Gaſtrodia*, *Dipodium* and *Sarcochilus*. The laſt-mentioned author alſo conſiders *Epipogium* as a diſtinct genus; ſee that article, and many of the reſt, in their proper places.

ORCHIDION was a name given by Mitchel to an orchideous genus from Virginia, which Linnæus called *Arethuſa*.

ORCHIDOCARPUM, a genus eſtabliſhed by Michaux upon the *Annona triloba* of Linnæus, with *pygmæa* and *grandiflora* of Bartram, to which is added a fourth ſpecies by the name of *O. parviflorum*. The flower is ſaid to be that of an *Unona* or *Uvaria*, but the fruit conſiſts of ſeveral *berries*, by abortion ſometimes nearly ſolitary, ſeſſile, rather large, egg or rather kidney-ſhaped. *Seeds* ſeveral, tunicated, ranged in a ſimple ſeries along the internal future. The name applies to the teſticular form of the fruit. Mich. Boreali-Amer. v. 1. 329.

ORCHIES, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the diſtrict of Douay; 12 miles S.S.E. of Lille. The place contains 2778, and the canton 13,100 inhabitants, on a territory of 105 kiliometres, in eight communes.

ORCHIL. See Archil.

ORCHILLA, or Horchilla, in *Geography*, a ſmall iſland in the Weſt Indies, near the coaſt of South America; or rather a cluſter of iſlands, the largeſt of which is in the form of a creſcent or half moon. Theſe iſles are ſeparated from one another by very ſhallow canals. On the E. and W. capes are ſome hills, which ſupply the goats with paſture. On the S.W. ſide of the main iſland the water is deep, and the ſhore is perpendicular, like a wall. The N.W. has ſcarcely any trees or graſs; but on the E. and W. both abound. The ſoil, from the low land, is ſalt, and produces few plants. The iſland has little freſh water, and the only animals upon it are goats and lizards. N. lat. 12°. W. long. 65° 20′.

ORCHIS, in *Botany*, an ancient name, alluding to the teſticular ſhape ſo frequent and ſo remarkable in the roots of many ſpecies. This reſemblance alone ſeems to have led to the uſe of theſe roots, in various ages and countries, as an aphrodiſiac or reſtorative. Linn. Gen. 461. Schreb. 502. Willd. Sp. Pl. v. 4. 8. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 918. Juſſ. 65. Lamarck Illuſtr. t. 726. Swartz Act. Holm. for 1800. 205. t. 3. f. A. Schrad. New Journ. v. 1. 6. t. 1. f. A. Brown Prodr. Nov. Holl. v. 1. 312, under *Habenaria*. Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. *Cal.* Perianth ſuperior, of three ſpreading leaves; the uppermoſt vaulted. *Cor.* Petals two, often approximated or attached to the upper leaf of the calyx. Nectary a ſpreading lip, with a tubular ſpur behind. *Stam.* Anther large, oblong, erect, attached in a parallel manner to the ſummit of the ſtyle, of two cells, opening in front; the maſſes of pollen club-ſhaped, attaching themſelves, each by

by its taper baſe, to one or two glands by the ſtigma, in one and the ſame pouch; ſtyle columnar, ſhort; ſtigma below the anther, convex, oblique. *Peric.* Capſule oblong, with three ribs, of one cell and three valves, ſplitting by three lateral fiſſures. *Seeds* numerous, minute, each with a chaffy tunic.

Eſſ. Ch. Upper leaf of the calyx vaulted. Lip of the nectary with a poſterior ſpur. Anther terminal, parallel. Maſſes of pollen ſtalked, their baſes approximated within a ſimple pouch.

The vaſt genus of *Orchis*, as it ſtands in Swartz and Willdenow, is now much curtailed by Mr. Brown, who excludes from it all the ſpecies that have not a ſimple pouch containing the baſes of both the maſſes of pollen together. Theſe are ſeparate, each with its own pouch, in *Ophrys*, (which beſides has no ſpur to the flower,) and ſeparate, without any pouch, which, ſo underſtood, becomes a large and very natural genus. The true *Orchis*, thus defined, is ſcarcely found out of Europe, one ſpecies only being known in America, none in the ſouthern hemiſphere, nor between the tropics. What Mr. Brown has found anſwering to this character are *O. morio*, Engl. Bot. t. 2059; *maſcula*, t. 631; *paluſtris*, Jacq. Ic. Rar. t. 181. Willd. n. 41; *uſtulata*, Engl. Bot. t. 18; *militaris*, t. 1873; *fuſca*, Jacq. Auſtr. t. 307, which was firſt publiſhed as *militaris* in Engl. Bot. t. 16; *papilionacea*, Linn. Sp. Pl. 1331, of which *rubra*, Jacq. Ic. Rar. t. 183. ſeems to us a variety; *palleus*, Jacq. Auſtr. t. 45; *coriophora*, Linn. Sp. Pl. 1332. Jacq. Auſtr. t. 122; *odoratiſſima*, Linn. Sp. Pl. 1335. Jacq. Auſtr. t. 264; *ſpectabilis*, Linn. Sp. Pl. 1337, found in North America; *ſambucina*, Linn. Sp. Pl. 1334. Jacq. Auſtr. t. 108; *pyramidalis*, Engl. Bot. t. 110; *hircina* (*Satyrium*) t. 34; *globoſa*, Linn. Sp. Pl. 1332. Jacq. Auſtr. t. 265; *latifolia*, Engl. Bot. t. 2308; and *maculata*, t. 632. We have here referred to Engl. Bot. only for ſuch ſpecies as are Britiſh. Mr. Brown ſuggeſts that there are Orchideous plants of European growth, eſpecially with purple flowers, that unqueſtionably belong to the preſent genus. Of the Britiſh ones beſides referred to it by Swartz, *Orchis bifolia*, Engl. Bot. t. 22; *Satyrium viride*, t. 94; and *albidum*, t. 505; are conſidered by Mr. Brown as *Habenariæ*.—*Orchis conopſea*, Engl. Bot. t. 10, though it has all the habit and general characters of a true *Orchis* as defined above, has no pouch at all for the maſſes of pollen, which are inſerted, as in *Habenaria*, into two naked glands, but they are approximated as in *Orchis*. Hence Mr. Brown, in the new edition of Ait. Hort. Kew. publiſhed under his care, has eſtabliſhed this plant as a new genus, called *Gymnadenia*, in alluſion to theſe naked glands.—The ſpecies of *Orchis* are found, ſome of them copiouſly in meadows or moiſt groves, others more partially and ſparingly on dry chalky hills. They flower in June or July, and are moſtly beautiful, ſome of the kinds very richly ſcented.

Orchis, in *Gardening*, contains plants of the herbaceous, bulbous-rooted, flowery perennial kind, of which the ſpecies cultivated are; the butterfly orchis (O. bifolia); the female or meadow orchis (O. morio); the male or early ſpotted orchis (O. maſcula); the man orchis (O. militaris); the broad-leaved or marſh orchis (O. latifolia); the ſpotted orchis (O. maculata); the long-ſpurred orchis (O. conopſea); and the purple bird's-neſt, or bird's-neſt orchis, (O. abortiva).

The ſecond ſort has varieties with purple flowers, with red flowers, with violet flowers, with fleſh-coloured flowers, and with white flowers.

The fourth ſpecies has alſo ſeveral varieties.

In the fifth there are different varieties.

And the ſixth varies with purple flowers, red flowers, and white flowers.

Method of Culture.—Theſe curious plants may all be introduced and preſerved in the pleaſure-grounds, by proper care in removing them from their native ſituations, which ſhould always be done when their leaves decline, being previouſly marked. When removed at other ſeaſons, they ſeldom ſucceed. They ſhould be taken up with balls of earth about their roots, and be immediately replanted, in a ſoil and ſituation as nearly as poſſible the ſame as that from which they were taken. When thus managed, they continue many years flowering in a ſtrong manner.

They afford much variety where the different kinds are in the borders, and other parts, in a proper manner.

Orchis-*Root*, in the *Materia Medica*, is otherwiſe named *ſalep*, vulgarly called *ſaloop*. See Salep.

ORCHAMENO, in *Geography*, a town of European Turkey, in the Morea, anciently "Orchamenus;" 25 miles W. of Argo.

ORCHOMENE, in *Ancient Geography*, a name by which ſeveral towns are diſtinguiſhed. Homer, in ſpeaking of that of Bœotia, gives it the epithet of Μινυειον, or Minyan; thus diſcriminating between this and another town of the ſame name in Arcadia. According to Pauſanias, Orchomene had been one of the moſt conſiderable towns of Greece. The Orchomenians appear by Homer's account to have been very powerful at the time of the Trojan war. When the ſons of Cadmus emigrated into Ionia, in order to eſtabliſh colonies, the Orchomenians took part in their expedition. Their power excited the jealouſy of the Thebans, who drove them from their town; and though they were re-eſtabliſhed by Philip, the father of Alexander, their condition was always feeble and declining. At Orchomene, among other objects of curioſity, were a temple of Bacchus, a temple conſecrated to the Graces, and a building called the treaſury of Minyas. Here were alſo the tomb of Minyas and that of Heſiod.—Alſo, a town of Arcadia, a little N.W. of Mantinæa. This town contained, among other monuments, two temples, one of Neptune, and another of Venus, and theſe divinities were repreſented in marble.

ORCHOTOMIA, from ορχις, *teſticle*, and τεμνω, *to cut*, in *Surgery*, the operation of removing the teſticle: caſtration.

ORCI Nuovo, in *Geography*, a fortreſs of Italy, in the department of the Mela, on the Oglio, built by the Venetians for the defence of their territories from the Spaniards, who were at that time in poſſeſſion of the Milaneſe; 15 miles S.W. of Breſcia.

Orci *Vecchia*, a town of Italy, in the department of the Mela; 14 miles S.W. of Breſcia.

ORCIANO, a town of Italy, in the duchy of Urbino; 16 miles S.E. of Urbino.—Alſo, a town of Etruria; 7 miles E. of Leghorn.

ORCIATICO, a town of Etruria; 8 miles W. of Volterra.

ORCIE'RES, a town of France, in the department of the Higher Alps, and chief place of a canton, in the diſtrict of Embrun; 9 miles N.W. of it. The place contains 1145, and the canton 2352 inhabitants, on a territory of 362½ kiliometres, in 3 communes.

ORCINO, a town of the department of Liamone, or the iſland of Corſica, and diſtrict of Ajaccio. The number of inhabitants in the canton is 2780.

ORCO, a river of Piedmont, which runs into the Po, near Chivazzo.

ORD *of Caithneſs*, a cape of Scotland, on the S.E. coaſt of the county of Caithneſs. N. lat. 58° 7'. W. long. 3° 28'.

ORDAVAR,

ORDAVAR, a town of Perſian Armenia; 50 miles S.E. of Naeſivan.

ORDEAL, ORDALIUM, a form of trial, that is, of diſcovering innocence or guilt; practiſed in England in the time of Edward the Confeſſor: and ſince, as low as king John and king Henry III.

The word, in the original Saxon, ſignifies *a great judgment*, formed of *or*, *great*, and *deal*, or *dele*, *judgment*.

It was called *purgatio vulgaris*, or *judicium Dei*, in oppoſition to *bellum* or *combat*, the other form of purgation: and alſo to the canonical purgation, which was by the oath of the party.

The ordeal was of various kinds; *viz.* that of fire, that of red-hot iron, that of cold water, that of judicial pottage, that of hallowed cheeſe, that of boiling water, that of a croſs, and that of dice laid on relics, covered with a woollen cloth. There were particular maſſes for each ſpecies of ordeal. See CORSNED, and *Judgment of the* CROSS.

The more popular kinds of ordeal were thoſe of red-hot iron and water: the firſt for freemen and people of faſhion; the ſecond for peaſants.

Fire-ordeal was performed either by taking up in the hand, unhurt, a piece of red-hot iron, of one, two, or three pounds weight; or elſe by walking, barefoot and blindfold, over nine red-hot plough-ſhares, laid lengthwiſe, at unequal diſtances; and if the party eſcaped without injury, he was adjudged innocent; but if it happened otherwiſe, as without colluſion it generally did, he was then condemned as guilty. The former was conducted in this manner: a ball of iron was prepared, of one, two, or three pounds weight, according to the nature of the accuſation. When all the prayers and other religious ceremonies were finiſhed, this ball was put into a fire, and made red-hot; after which it was taken out. The priſoner having ſigned himſelf with the croſs, and ſprinkled his hand with holy water, took the ball of hot iron in his hand, and carried it to the diſtance of nine feet; after which his hand was put into a bag, and ſealed up for three days; at the expiration of which it was examined, in the preſence of twelve perſons of each party. If any marks of burning appeared upon it, the accuſed was found guilty; if none, he was declared innocent. Ducange Gloſs. Voc. *Ferrum Candens*.

It is a popular ſtory in our hiſtories, that Emma, mother of Edward the Confeſſor, being accuſed of too much familiarity with Alwyn, biſhop of Wincheſter, demanded the ordeal of red-hot iron; and paſſed barefooted and hoodwinked over nine red-hot plough-ſhares, without touching any of them.

Water-ordeal was performed either by plunging the bare arm up to the elbow in boiling water, and eſcaping unhurt; or by caſting the perſon ſuſpected into a river or pond of cold water, and if he floated therein, without any action of ſwimming, it was deemed an evidence of his guilt, but if he ſunk he was acquitted.

The preparations by faſtings, prayers, and other religious exerciſes, were the ſame for both theſe ordeals. In the hot-water ordeal, the perſon to be tried was conducted with great ſolemnity to the church, where the prieſt began by ſaying certain prayers ſuitable to the occaſion; after which maſs was celebrated; and before the accuſed was permitted to communicate, he was adjured, in the moſt awful form of words, to confeſs if he was guilty. Fire was then kindled under a pot filled with water; and while the water was heating, the prieſt ſaid many prayers compoſed for that purpoſe. As ſoon as the water began to boil, a ſtone was ſuſpended in it by a ſtring, at the depth of one, two, or three palms, according to the nature of the accuſation. The pot was then taken down and placed by the ſide of the fire; and the priſoner having ſaid the Lord's prayer (not very rapidly we may preſume), and marked himſelf with the ſign of the croſs, plunged his naked hand and arm into the water, and ſnatched out the ſtone. His arm was inſtantly wrapped in linen cloths, and put into a bag, which was ſealed by the judge in the preſence of the ſpectators. The priſoner was then reſtored to the prieſt, who produced him in the ſame church at the end of three days; when the bag was opened, the bandages taken off, and the arm examined by twelve of his own friends, and twelve of the friends of the proſecutor. If any marks of ſcalding then appeared upon the arm, the priſoner was found guilty: if no ſuch marks could be diſcovered, he was acquitted. Ducange Gloſſ. apud. Voc. *Aquæ ferventis judicium*.

The ordeal by cold water was thus conducted: the perſon who was tried was put under the direction of a ghoſtly father, of great reputation for his ſanctity, who obliged him to perform many extraordinary acts of devotion, and to keep a rigorous faſt for three days. When this faſt was ended, and the day appointed for the trial came, the priſoner was publicly conducted to the church, where the prieſt celebrated maſs; and before he permitted the accuſed to communicate, he addreſſed him in the following ſolemn ſtrain: "I adjure thee, O man, by the Father, Son, and Holy Ghoſt, by the true Chriſtianity which you profeſs, by the only begotten Son of God, by the holy Trinity, by the holy Goſpel, and by all the holy relics in this church, that you do not preſume to communicate, or approach this holy altar, if you have committed this crime, conſented to it, or know who committed it." If the priſoner made no confeſſion, the prieſt gave him the communion, ſaying, "Let this body and blood of our Lord Jeſus Chriſt be received by you as a probation this day." After this a quantity of holy water was conſecrated, and then the whole company left the church, and went in proceſſion to the pool where the ordeal was to be performed. When they arrived there, the prieſt gave the priſoner a draught of the holy water, ſaying, "Let this holy water be to thee a probation this day." If the priſoner ſtill continued to deny his guilt, the prieſt then pronounced a long and very fervent prayer over the pool, adjuring it by every thing that was divine and venerable in heaven or on earth, that if the perſon to be thrown into it was guilty, it would reject him, and cauſe him to float upon its ſurface; but if he was innocent, that it would receive him into its boſom. The priſoner was then ſtripped naked, his hands and legs made faſt, and a rope tied about his middle, with a knot upon it, at the diſtance of a yard and half from his body, and thrown into the pool. If he floated, which was hardly to be expected, he was taken out, and declared guilty; if he ſunk ſo deep as to carry the knot of the rope under water, he was inſtantly pulled out, before he could receive any injury. Muratori Antiq. t. 3. Wilkins's Leg. Saxon, p. 61.

This ordeal was evidently a very uncertain teſt of guilt or innocence; but the great ſolemnity with which it was adminiſtered, might ſometimes ſtrike terror into the minds of criminals, and bring them to confeſſion. In this ordeal it is preſumed that God would work a miracle for the detection of guilt: in the ordeals of hot water and hot iron, the preſumption was, that he would work a miracle for the vindication of innocence: but for either of theſe preſumptions there was no ſolid foundation.

It is eaſy to trace out the traditional relics of this water-ordeal, in the ignorant barbarity ſtill practiſed in many countries, to diſcover witches, by caſting them into a pool of water, and drowning them to prove their innocence. This

purgation by ordeal ſeems to have been very ancient, and very univerſal, in the time of ſuperſtitious barbarity. It was known to the ancient Greeks, vide Antigone of Sophocles, v. 270. And Grotius Com. on Numb. v. 17. gives many inſtances of water-ordeal, in Bithynia, Sardinia, and other places.

It was very anciently known in Perſia, and perhaps originated from their ſuperſtitious veneration for fire. Records of trial by ordeal remain above 500 years before the Chriſtian era. It is ſtill in practice, where ſatisfactory evidence cannot be obtained, among the Gentoos, in Hindooſtan, and of very high antiquity. It is mentioned ſeveral times in the code of Gentoo laws, as a common mode of proof. The modes of this ordeal are various in India, according to the choice of the party, or nature of the offence; but the infallibility of the reſult is to this day as implicitly believed, as it could have been in the darkeſt ages of antiquity. See chap. iii. of the Code of Gentoo Laws, by Halhed.

The moſt reſpectable authors, ancient and modern, attribute the invention of water-ordeal, in the Chriſtian church, to pope Eugenius II.; though Le Brun, a prieſt of the Oratory, maintains, that it was more ancient. However this be, the cuſtom was condemned and abrogated, by the authority of Lewis the Meek, about the year 829. It was afterwards revived, and practiſed in the 10th, 11th, and 12th centuries.

The firſt account we have of Chriſtians appealing to the fire-ordeal, as a proof of their innocence, is that of Simplicius, biſhop of Autun, who lived in the 4th century. This prelate, as the ſtory is related, before his promotion to the epiſcopal order, had married a wife, who loved him tenderly, and who, unwilling to quit him after his advancement, continued to ſleep in the ſame chamber with him. The ſanctity of Simplicius ſuffered, at leaſt in the voice of fame, by the conſtancy of his wife's affection: and it was rumoured about, that the holy man, though a biſhop, perſiſted, in oppoſition to the eccleſiaſtical canons, to taſte the ſweets of matrimony; upon which, his wife, in the preſence of a great concourſe of people, took up a conſiderable quantity of burning coals, which ſhe held in her clothes, and applied to her breaſts, without the leaſt hurt to her perſon or her garments, as the legend ſays, and her example being followed by her huſband, with the like ſucceſs, the ſilly multitude admired the miracle, and proclaimed the innocence of the loving pair. A ſimilar trick was played by St. Brice, in the fifth century. Moſh. Eccl. Hiſt. vol. ii. 1768.

The practice of ordeal obtained very generally in more modern times; and even in England ſo late as king John's time, we find grants to the biſhops and clergy to uſe the *judicium ferri, aquæ, et ignis*. And both in England and Sweden, the clergy preſided at this trial, and it was only performed in the churches or in other conſecrated ground. However, the canon law declared very early againſt trial by ordeal, as being the fabric of the devil. Upon this authority, though the canons themſelves were of no validity in England, it was thought proper (as had been done in Denmark, above a century before,) to diſuſe and aboliſh this trial entirely in our courts of juſtice, by an act of parliament of 3 Hen. III. according to ſir Edward Coke, or rather by an order of the king in council. Blackſt. Com. vol. iv.

If we imagine that few or none eſcaped conviction, who expoſed themſelves to theſe ordeals, we ſhall be much miſtaken: for the hiſtories of thoſe times in which they were in uſe contain innumerable examples of perſons plunging their naked arms into boiling water, handling red-hot balls of iron, and walking upon burning plough-ſhares, without receiving the leaſt injury. (Ducange Gloſſ. t. iii. p. 399, &c.) Several learned men have been much puzzled to account for this, and have been diſpoſed to think that Providence graciouſly interpoſed in a miraculous manner for the preſervation of injured innocence. But upon examining every circumſtance of theſe ordeals with due attention, we ſhall perceive reaſon ſufficient to ſuſpect that the whole was a groſs impoſition on the credulity of mankind. The accuſed perſon was committed wholly to the prieſt who was to perform the ceremony, three days before the trial, in which he had time enough to bargain with him for his deliverance, and give him inſtructions how to act his part. On the day of trial, no perſon was permitted to enter the church but the prieſt and the accuſed, till after the iron was heated; when twelve friends of the accuſer and twelve friends of the accuſed, and no more, were admitted, and arranged along the wall on each ſide of the church, at a reſpectful diſtance. After the iron was taken out of the fire, ſeveral prayers were ſaid, the accuſed drank a cup of holy water, and ſprinkled his hand with it, which, if the prieſt was indulgent, might take a conſiderable time. The ſpace of nine feet was meaſured by the accuſed himſelf with his own feet, and he would probably give but ſcanty meaſure. He was obliged only to touch one of the marks with the toe of his right foot, and allowed to ſtretch the other foot as far towards the other mark as he could: ſo that the conveyance was almoſt inſtantaneous. His hand was not immediately examined, but wrapped in cloth, prepared for that purpoſe, three days. From all theſe precautions may we not ſuſpect that theſe prieſts were in poſſeſſion of ſome ſecret that ſecured the hand from the impreſſions of ſuch a momentary touch of hot iron, or removed all appearance of theſe impreſſions in three days; and that they made uſe of this ſecret when they ſaw reaſon? Moreover, we meet with no example of any champion of the church, who ſuffered the leaſt injury from the touch of hot iron in this ordeal; but when any one was ſo fool-hardy as to appeal to this, or to that of hot water, with a view to deprive the church of any of her poſſeſſions, he never failed to burn his fingers, and loſe his cauſe. Ducange Gloſſ. t. iii. Henry's Hiſt. vol. iii.

ORDEFF, or OREDEF, a word frequently uſed, in charters of privileges, for a liberty whereby a man claims the ore found in his own ground.

It properly ſignifies ore lying under ground; as a *delf* or *deff of coal* is coal lying in veins under ground.

ORDER, in *Architecture*. The word order is equivalent to arrangement, and in architecture may be conſidered as a decorated imitation of ſuch a portion of a primitive hut, of a certain conſtruction, as might comprehend the whole deſign by a continuity and repetition of its parts. The hut originally conſiſted of a roof or covering, ſupported by poſts made of the trunks of trees, in four rows, forming a quadrangular encloſure. Beams were laid upon the tops of the poſts, in order to connect them, in their longitudinal direction, in one body. To ſupport the covering, timbers were laid from beam to beam acroſs the breadth; and to throw off the wet, other beams were laid parallel to thoſe reſting upon the poſts, but jutting farther over on each ſide of the edifice: and theſe again ſupported inclined timbers which overhung their ſupports, and formed a ridge in the middle of the roof for throwing off the wet; and thus the part ſupported formed three principal diſtinct portions, which, in proceſs of time, were decorated with certain mouldings, or other ornaments, each part ſtill preſerving its diſtinct maſs, though perhaps not exactly ſimilar

to the original form. The three parts, taken as a whole, were called the entablature: the lower part, conſiſting of the linteling beams, was called the epiſtyle, or architrave; the middle part, which receded from the epiſtyle, was called the zoophorus, or frieze; and the upper part, which projected conſiderably over the epiſtyle, being in imitation of the ends of the roof, was called the cornice.

Therefore the entablature conſiſts of a cornice, frieze, and architrave.

The poſts received the name of columns, which always conſiſt of two principal diviſions at leaſt, and frequently of three. The columns were ornamented at the top in imitation of the ſtones laid upon the poſts in the original wooden hut, for throwing off the rain. Theſe decorations at the top received the name of capital, and each of the wooden poſts, that of ſhaft.

When ornaments were added to the foot of the ſhaft they were termed the baſe.

The order, therefore, conſiſts principally of a column and entablature. The column is ſubdivided into a ſhaft and capital, or, at moſt, into three principal parts, a baſe, ſhaft, and capital; and the entablature, as has been obſerved, into architrave, frieze, and cornice. Theſe parts are again divided into ſmaller portions, termed mouldings, or other ornaments.

There are three orders in architecture, though the modern writers generally enumerate five, but without any authority. Theſe three orders are named Doric, Ionic, and Corinthian, according to the place in which they were invented.

Their hiſtory according to Vitruvius, is detailed under the article CIVIL *Architecture*.

Except in the general forms above ſpecified, there is no ſtandard of proportion common to the three orders, each having its own ſymmetry. The capitals are their diſtinguiſhing features. The Doric entablature is peculiar to the Doric. The Ionic entablature may be applied to the Corinthian with equal propriety, as the remains of Grecian antiquity amply teſtify. The proportions of columns vary in the three orders, from five to ten diameters, the ſtandard being the diameter of a ſection of the ſhaft at the bottom. The ſhafts of the columns are the fruſtums of cones; they are ſometimes of a conoidal form, which however is not ſo agreeable to the archetype as the conic fruſtum, and in the antique they are generally fluted. The fluting of the Doric is peculiar to itſelf. The columns of this order are in height fewer diameters than thoſe of the other two; and ſuppoſing the diameter at the baſe in the three orders to be equal, the altitudes of the columns will increaſe from the Doric to the Corinthian, ſo that the Ionic column is the medium between the other two. The height of the entablature of each order may be generally ſtated at two diameters of its column. The diminution of the ſhafts is not equal in all the orders: that of the Doric varies from one-fourth to one-fifth, the Ionic and Corinthian from one-fifth to one-ſixth. Neither are the cornice, frieze, or architrave in an equal ratio to each other. The height of the Doric cornice is about one-fourth of the height of the entablature; that of the Ionic one-third, and in moſt examples conſiderably more. The height of the architrave and that of the frieze of the Doric entablature are, in general, equal. In the Ionic and Corinthian the architrave is higher than the frieze, but of leſs height than the cornice. Though the moderns have claſſed two other orders with the three Grecian, they have no authority for this addition. Vitruvius mentions Tuſcan temples and various kinds of capitals uſed for the Corinthian, but no where ſpeaks of them as forming a diſtinct order. The peculiarities of each are noticed under its reſpective title; ſee DORIC, IONIC, and CORINTHIAN *Order*. See alſo COMPOSITE and TUSCAN *Order*.

ORDER, *Attic*. See ATTIC.

ORDER, *Caryatic*. See CARYATIDES.

ORDER, *French*, is a new-contrived order, wherein the capital conſiſts of attributes agreeing to that people, as cocks' heads, fleur de lis, &c.

Its proportions are Corinthian. Such is that of M. Le Brun, in the grand gallery at Verſailles; and that of M. Le Clerc.

M. Le Clerc gives a ſecond Tuſcan order, and a Spaniſh order, beſides his French order. The Tuſcan he ranks between the firſt Tuſcan and Doric. Its height he makes 23 ſemidiameters 22 minutes; the column to have 15, the pedeſtal 5, and the entablature 3, and 22 minutes: and he propoſes its frieze to be adorned with turtles, which are the arms of Tuſcany.

The Spaniſh order he places between the Corinthian and Compoſite. The whole order he makes 30 ſemidiameters, 28 minutes; of which the column has 9 and 25 minutes, the pedeſtal 16 and 18 minutes, and the entablature 4 and 15 minutes. The horns of the abacus he ſuſtains with little volutes; the middle, in lieu of a roſe, has a lion's ſnout; that animal being the ſymbol of Spain, and expreſſing the ſtrength, gravity, and prudence of that nation.

There has been alſo an order, where lions and unicorns have been made to iſſue from the volutes, in compliment to the arms of the king of England, and called the *Britannic* order; but all theſe diſtinctions are alterations without improvement, and encumber rather than ornament the original figure of the antique capital.

ORDERS, *Greek*. See GREEK.

ORDER, *Gothic*. See GOTHIC.

ORDER, *Perſian*. See PERSIAN.

In ſome caſes the caryatides, or Perſian order, is introduced as an attic, over columns; as in the front of the Royal Academy, in the Strand.

ORDER, *Ruſtic*. See RUSTIC.

ORDER, in *Aſtronomy*, &c. A planet is ſaid to go according to the order of the ſigns, when it is direct; proceeding from Aries to Taurus, thence to Gemini, &c.—It goes contrary to the order or ſucceſſion of the ſigns, when it is retrograde; *i. e.* when it goes back from Piſces to Aquarius, &c.

ORDERS, in *Syſtematical Botany*, are uſually ſubdiviſions of claſſes. The orders of Tournefort are diſtinguiſhed by the fruit; thoſe of Linnæus moſtly by the number of ſtyles, at leaſt in his firſt thirteen claſſes; thoſe of the 14th and 15th are diſcriminated by the fruit; of the 16th, 17th, and 18th, by the number of the ſtamens, which is likewiſe the caſe in the 20th, 21ſt, and 22d claſſes; the orders of the 19th claſs being characteriſed by the nature of the florets, while the orders of the 24th *Cryptogamia* are natural aſſemblages. See CLASSIFICATION and NATURAL *Orders*.

ORDERS, in *Law*, are of ſeveral ſorts, and by divers courts; as of the chancery, king's bench, &c. Orders of the court of chancery, either of courſe or otherwiſe, are obtained on the petition or motion of one of the parties in a cauſe, or of ſome other intereſted in, or affected by it; and they are ſometimes made upon hearing, and ſometimes by conſent of parties. Pract. Solic. 26.

ORDERS, in a *Military Senſe*, denote all that is lawfully commanded by ſuperior officers. Thus, orders are given out every day, whether in camp, garriſon, or on a march, by the commanding officer; which orders are afterwards

given to every officer in writing by their reſpective ſerjeants.

The orders of the commander-in-chief are thoſe which iſſue directly from his office, for the government of the army at large, or for any ſpecific purpoſe. Theſe orders are ſanctioned by the king, and are irrevocable elſewhere.

General orders are ſuch as are given by the general who commands; who iſſues them in writing to the adjutant-general, and he ſends exact copies of them to the general officers of the day, and diſtributes them at his own quarters to all the brigade-majors, who daily go to head-quarters for that purpoſe, where they write down every thing that is dictated to them; and from thence they go and communicate the orders at an appointed place to the different majors or adjutants of the regiments which compoſe that brigade: they firſt read them to their colonels and lieutenant-colonels, or majors, and they dictate them to the ſerjeants of companies, and this is done by the ſerjeant-major, who writes them correctly down in their orderly books, and brings them to all the officers belonging to the company.

There are alſo *garriſon*, *brigade*, *regimental*, *ſtanding*, &c. orders.

ORDER, in *War*, denotes an arrangement of the parts of an army, either by land or ſea, whether for marching, ſailing, or engaging.

ORDER *of Battle*. See BATTLE and LINE.

An ORDER *of March* is diſpoſed in two or three columns, according to the ground. The orders and evolutions make the ſubject of the ſcience of tactics. See EVOLUTION and MARCH.

ORDER is more particularly uſed for the equal diſtance of one rank or file from another.

The uſual order in files is three feet; in ranks ſix feet. The open or marching order is twice as much. See MARCH.

ORDER, *Cloſe*, *Open*, &c. See BATTALION.

ORDER, in *Rhetoric*, is the placing of each word and member of a ſentence in ſuch a manner, as will moſt contribute to the force, beauty, or evidence of the whole; according to the genius and cuſtom of different languages. With regard to order, we may obſerve in general, that, in Engliſh, the nearer we keep to the natural or grammatical order it is generally the beſt; but in Latin, we are to follow the uſe of the beſt writers; a joint regard being always had to the judgment of the ear, and the perſpicuity of the ſenſe, in both languages. See DISPOSITION.

ORDER is alſo uſed for a claſs or diviſion of the members of the body of a ſtate; with regard to aſſemblies, precedence, &c.

In this ſenſe, order is a kind of dignity, which, under the ſame name, is common to ſeveral perſons; and which, of itſelf, does not give them any particular public authority, but only rank, and a capacity of arriving at honours and employments.

To abridge this definition, order may be ſaid to be a dignity attended with an aptitude for public employ. By which it is diſtinguiſhed from an office, which is the exerciſe of a public truſt.

In this ſenſe, nobility is an order, &c. The clericate is alſo an order, &c.

ORDER is alſo the title of certain ancient books, containing the divine office, with the order and manner of its performance.

Roman order is that in which are laid down the ceremonies which obtain in the Romiſh church. See RITUAL.

ORDERS, by way of eminence, or *holy* orders, denote a character peculiar to eccleſiaſtics, whereby they are ſet apart for the miniſtry.

This the Romaniſts make their ſixth ſacrament.

In the reformed churches there are but three orders; *viz.* biſhops, prieſts, and deacons. In the Romiſh church there are ſeven, excluſive of the epiſcopate: all which the council of Trent enjoins to be received, and believed, on pain of anathema.

They are diſtinguiſhed into *petty*, or *ſecular* orders; and *major*, or *ſacred* orders.

ORDERS, *the petty*, or *minor*, are four; *viz.* thoſe of doorkeeper, exorciſt, reader, and acolyth.

Thoſe in petty orders may marry without any diſpenſation: in effect, the petty orders are looked on as little other than formalities, and as degrees neceſſary to arrive at the higher orders. Yet the council of Trent is very ſerious about them: enjoins that none be admitted into them without underſtanding Latin: and recommends it to the biſhops, to obſerve the intervals of conferring them, that the perſons may have a ſufficient time to exerciſe the function of each order: but it leaves the biſhops a power of diſpenſing with thoſe rules. ſo that the four orders are uſually conferred the ſame day, and only make the firſt part of the ceremony of ordination.

The Greeks diſavow theſe petty orders, and paſs immediately to the ſub-diaconate; and the reformed to the diaconate.

Their firſt riſe Fleury dates in the time of the emperor Juſtinian. There is no call nor benefice required for the four petty orders; and a baſtard may even enjoy them without any diſpenſation; nor does bigamy diſqualify.

ORDERS, *Sacred*, or *Major*, we have already obſerved, are three; *viz.* thoſe of deacon, prieſt, and biſhop.

The council of Trent, retrieving the ancient diſcipline, forbids any perſon being admitted to the major orders, unleſs he be in peaceable poſſeſſion of a benefice ſufficient for a decent ſubſiſtence: allowing no ordinations on patrimonies or penſions: except where the biſhop judges it for the ſervice of the church.

A perſon is ſaid to be promoted to orders *per ſaltum*, when he has not before paſſed the inferior orders. The council of Conſtantinople forbids any biſhop being ordained without paſſing all the degrees; yet church hiſtory furniſhes us with inſtances of biſhops conſecrated, without having paſſed the order of prieſthood; and Panormus ſtill thinks ſuch an ordination valid.

ORDERS, *Military*, are companies of knights, inſtituted by kings and princes; either for defence of the faith, or to confer marks of honour, and make diſtinctions among their ſubjects.

There have been five orders, purely military, in England; *viz.* thoſe of the knights of the Garter, knights Bannerets, knights of the Bath, knights Bachelors, and knights Baronets.

The French have had five military orders; *viz.* that of the Genette, inſtituted by Charles Martel; but which ſoon fell. The order of the Virgin Mary, ſince called the order of the Star, inſtituted by king John, in 1352. The order of St. Michael, inſtituted in 1469, by Lewis IX. The order of the Holy Ghoſt, or the Blue Ribband; the members of which are firſt to be knights of St. Michael. And the order of St. Louis, inſtituted by Louis XIV., in 1693. The princes of the blood, marſhals of France, admirals, and generals, become knights of St. Louis by their offices.

ORDER *of Alcantara*, *of Amaranth*, *of Argonauts*, *of the Band of Calatrava*, *of Chriſt*, *of the Croſs*, *of the Elephant*, *of the Ermine*, *of the Golden Fleece*, *of St. James*, *of the Knot*, *of St. Lazarus*, *of the Roſary*, *of the Star*, *of the*

the Stole, and of the Thiſtle, &c. See the reſpective articles. See the references under KNIGHTS.

ORDER *of Merit*. See MERIT.

ORDER *of St. Alexander Newſki*, or the red ribband, was inſtituted by Peter I., emperor of Ruſſia; but the czarina Catherine I. conferred it in the year 1725. See ALEXANDER NEVSKOI.

ORDERS, *Religious military*, are thoſe inſtituted in defence of the faith, and privileged to ſay maſs; and who are prohibited marriage, &c.

Of this kind are the knights of Malta, or of St. John of Jeruſalem. Such alſo were the knights Templars, the knights of Calatrava, knights of St. Lazarus, Teutonic knights, &c. See MALTA, TEMPLAR, &c.

Father Putignani accounts thoſe military orders where marriage is not allowed, real religious orders. F. Papebroch ſays, it is in vain to ſearch for military orders before the twelfth century.

ORDERS, *Religious*, are congregations, or ſocieties of monaſtics, living under the ſame ſuperior, in the ſame manner, and wearing the ſame habit.

Religious orders may be reduced to five kinds; *viz.* monks, canons, knights, mendicants, and regular clerks. See MONK, CANON, &c.

Father Mabillon ſhews, that till the ninth century, almoſt all the monaſteries in Europe followed the rule of St. Benedict; and that the diſtinction of orders did not commence till upon the re-union of ſeveral monaſteries into one congregation: that St. Odo, abbot of Cluny, firſt began this reunion, bringing ſeveral houſes under the dependence of Cluny: that, a little afterwards, in the eleventh century, the Camaldulians aroſe; then, by degrees, the congregation of Vallombroſa; the Ciſtercians, Carthuſians, Auguſtines: and at laſt, in the thirteenth century, the Mendicants. He adds, that Lupus Servatus, abbot of Ferrieries in the ninth century, is the firſt that ſeems to diſtinguiſh the order of St. Benedict from the reſt, and to ſpeak of it as a particular order.

White order denoted the order of regular canons of St. Auguſtine. See AUGUSTINS.

Black order denoted the order of Benedictines.

Theſe names were firſt given theſe two orders from the colour of their habit; but are diſuſed ſince the inſtitution of ſeveral other orders, who wear the ſame colours.

Grey order was the ancient name of the Ciſtercians; but ſince the change of the habit, the name ſuits them no more.

ORDER *of Charity*. See CHARITY.

ORDER *of St. Saviour*. See SAVIOUR.

ORDER, *Third*. See THIRD.

ORDER, in the *Geometry of Curves*. See GENDER, LINE, and CURVE.

ORDERS, *Book of*. See BOOK.

ORDER, *Interlocutory*. See INTERLOCUTORY.

ORDERIC, VITAL, in *Biography*, an eccleſiaſtical hiſtorian in the twelfth century, of French extraction, but born in England about the year 1075. When he was eleven years old he was ſent to Normandy, where he took the religious habit in the abbey of Ouche, and in 1091, he was ordained ſubdeacon. It was not till 1108, when he was in his thirty-third year, that he received prieſts' orders from the hands of the archbiſhop of Rouen. He paſſed his life wholly occupied in ſtudy and devotion, without filling any of the poſts belonging to his order. He died in 1143. As an author he is known by a work entitled "Hiſtoriæ Eccleſiaſticæ, lib. xiii." containing the hiſtory of the Chriſtian church, from the birth of Chriſt to the year 1142. This work is ſaid to furniſh many intereſting facts, not to be met with elſewhere, which relate to the hiſtories of Normandy, of France, and England. It was firſt edited by Ducheſne, among his "Hiſtoriæ Normannorum Scriptores." Gen. Biog.

ORDERLY SERJEANT, and *Orderly Men*, in *Military Language*, are thoſe who are appointed to attend on general officers, or ſuch other officers as are entitled to ſuch, who walk behind them with their arms.

ORDERLY *Book*, is a book provided for every company, in which the ſerjeants write down both general and regimental orders, that the officers may read them.

ORDIK, in *Geography*, a town of European Turkey, in Beſſarabia; eight miles N. of Iſmael.

ORDINAL, ORDINALE, a book containing the order or manner of performing divine ſervice; and ſeems to be the ſame with that which was called the "pie" or "portuis," and ſometimes "portiforium." See RITUAL.

ORDINAL, in *Grammar*, an epithet given to ſuch numbers as mark the order of things, or in what rank they are placed.

Thus, firſt, ſecond, tenth, hundredth, &c. are ordinal numbers. See CARDINAL.

ORDINANCE, or ORDONNANCE, a law, ſtatute, or command, of a ſovereign or ſuperior.

Ordinance of parliament, is ordinarily uſed in the ſame ſenſe as ſtatute, or act of parliament.

In the parliament-rolls, acts are often called ordinances of parliament. Though in ſome caſes we find a difference made between the two; ordinances being only temporary things, by way of prohibition; and capable of being altered by the commons alone; whereas an act is a perpetual law, and cannot be altered but by king, lords, and commons.

Sir Edward Coke aſſerts, that an ordinance of parliament differs from an act, as the latter can only be made by the king, and the threefold conſent of the eſtates; whereas the former may be made by one or two of them.

Ordinance of the Foreſt, is a ſtatute made in the thirty-fourth year of Henry I. relating to foreſt matters. See FOREST.

In the French juriſprudence, ordonnances are ſuch laws as are eſtabliſhed by the king's authority alone. All ordonnances begin with *à tous preſens & à venir ſalut*. See CAPITULAR.

ORDINANCE, or *Ordnance*, is alſo a general term for all ſorts of great guns, or cannon, mortars, &c. uſed in war. See CANNON and GUN.

The ſtrength and ſerviceableneſs of a piece of ordnance depends much on the thickneſs of the metal, eſpecially about its chamber and breech, which is called its *fortification*.

Of this there were three degrees, both for cannons and culverins. Such were the ordinarily fortified, alſo called *legitimate pieces*. Thoſe whoſe fortification is leſſened, were called the *baſtard pieces*. Thoſe doubly fortified were called *extraordinary pieces*.

The fortification of a gun is reckoned from the thickneſs of the metal at the touch-hole, at the trunnions, and at the muzzle, in proportion to the diameter of the bore. For the dimenſions of pieces of ordnance now in uſe, and of their various parts, ſee CANNON.

ORDINANCE, in *Painting*. See ORDONNANCE.

ORDINANCE, or *Ordnance Office*, is the ſtanding grand magazine of arms, habiliments, inſtruments, and utenſils of war. as well by ſea as land; not only of thoſe lodged in the Tower, but in all the garriſons, caſtles, forts, &c. in Great Britain,

Britain, from whence, as occaſion requires, his majeſty's armies are ſupplied.

The *board* of ordnance directs and regulates every thing that relates to the artillery and garriſons. In 1683, the ſuperintendance of this board was committed to five chief officers, beſides the maſter-general.

The firſt and principal is the *maſter-general*, from whom are derived all orders and diſpatches relating to the ſame, as the ſervice ſhall beſt require, and who has the ſole command of the royal regiment of artillery. This poſt has often been annexed to the office of general and commander-in-chief. The ſame military reſpect is paid to the maſter-general of the ordnance, as to generals of horſe and foot; that is, on all occaſions to have the march beat to him, and to be ſaluted by officers, the colours excepted. The firſt maſter of the ordnance upon record was Rauf Bigod, who was appointed to this office for life 2d of June 1483.

Under him is a *lieutenant-general* of the ordnance, who receives orders from the maſter-general, and the reſt of the prime officers at the board; ſees them duly executed; orders the firing of guns on days of rejoicing; and ſees the train of artillery fitted out when ordered to the field.

Next to him is the *ſurveyor-general*, who has the inſpection of the ordnance, ſtores, and proviſions of war, in the cuſtody of the ſtore keepers; he allows all bills of debts, keeps a check on labourers, &c.

Under theſe is a *clerk* of the ordnance, who records all orders or inſtructions given from the government of the office; with all patents, grants, names of officers, &c. draws all eſtimates for proviſions, and ſupplies all letters, inſtructions, commiſſions, deputations, contracts, &c. and ſerves as a check between the two accomptants of the office, the one for money, the other for ſtores.

This office has alſo a *ſtore-keeper*, who takes into his cuſtody all ordnance, ammunition, ſtores, &c. thereto belonging; and indents and gives in legal ſecurity for the ſafe keeping thereof; and renders an exact account from time to time.

Here is alſo a *clerk of the deliveries*, whoſe duty is to draw up all proviſions, either at the Tower, or any other of his majeſty's magazines, to ſee them duly executed, &c.

To this office alſo belongs a *treaſurer* and *pay-maſter*, through whoſe hands paſſes the money of the whole office, as well for payment of ſalaries, as debentures.

Under theſe ſuperior officers belonging to the civil branch of the ordnance, there are ſecretaries and clerks, &c. The military branch of the ordnance is under the direction of a chief engineer, &c. See ENGINEER.

ORDINANCE, or *Ordnance Bills*, commonly called *ordnance debentures*, are bills iſſued by the board of ordnance on the treaſurer of that office, for the payment of ſtores, &c. Theſe are not payable at any certain time, and do not bear any intereſt, ſo that the diſcount upon them is often very high: but they are ſeldom much above two years in arrear.

ORDINANCE, *Spiking up the*. See SPIKING.

ORDINARII, in *Antiquity*, were a ſort of gladiators; being thoſe appointed to exhibit combats on certain ſtated days, &c.

ORDINARIO, Ital. common, uſual, in *Muſic*, as *tempo ordinario*, the uſual time. Theſe words are uſually prefixed to movements in common time, for "moderately quick."

ORDINARY, ſomething that happens, or paſſes frequently, or uſually.

We ſay, the ordinary courſe of things: whatever is done without miracles, is done by ordinary agents.

ORDINARY *Culverin*. See CULVERIN.

ORDINARY *Minion*, &c. See MINION, &c.

ORDINARY, *Ambaſſador*, or *Envoy in*. See EMBASSADOR, and ENVOY.

ORDINARY is alſo applied to ſeveral officers and ſervants belonging to the king's houſhold, who attend on common occaſions. Thus we ſay, phyſician in ordinary, &c.

ORDINARY is a term applied to ſhips of war *laid-up* in harbours near the royal dock-yards. It is alſo the eſtabliſhment of the perſons employed by the government to take charge of them, which are ſo laid-up. Theſe are principally compoſed of ſuperintendent maſters, warrant-officers, and ſervants of the ſaid ſhips, except the purſer, alſo a certain number of ſeamen in time of peace, according to the ſize of the ſhip. But in war there is a crew of labourers enrolled in the liſt of the ordinary, who paſs from ſhip to ſhip occaſionally to pump, clean, moor, or tranſport them whenever it is required.

The term ordinary is alſo applied to diſtinguiſh the inferior ſailors from the able ſeamen. Thus the latter are rated *able* on the navy books, and have a monthly pay ſuperior to that of thoſe who are rated *ordinary*.

ORDINARY, *Ordinarius*, in the *Civil Law*, is any judge veſted with authority to take cognizance of cauſes, in his own right, as he is a magiſtrate; and not by deputation.

ORDINARY *Court of Chancery*. See PETTY *Bag*.

ORDINARY, in *Common* and *Canon Law*, denotes him who has ordinary or immediate juriſdiction in eccleſiaſtical cauſes, as of courſe and common right; in oppoſition to perſons who are *extraordinarily* appointed.

In which ſenſe archdeacons are ordinaries. Though the appellation be moſt frequently given to the biſhop of the dioceſe, who has the ordinary eccleſiaſtical juriſdiction, and the collation to benefices therein. However, in a more general acceptation, the word *ordinary* ſignifies (as above ſtated) any judge, authoriſed to take cognizance of cauſes in his own proper right, as he is a magiſtrate, and not by way of deputation or delegation.

There are ſeveral chapels, chapters, abbies, &c. exempted from the juriſdiction of the ordinary.

The archbiſhop is ordinary of the whole province, to viſit, and receive appeals from the inferior judicatures.

The Romiſh canoniſts call the pope *ordinary* of *ordinaries*, ſince by the Lateran council he has uſurped the right of collating, by prevention, to all benefices; in excluſion of the ordinary collators.

ORDINARY *of Aſſize and Seſſions*, was a deputy of the biſhop of the dioceſe, anciently appointed to give malefactors their neck-verſes, and judge whether they read or not; alſo to perform divine ſervice for them, and aſſiſt in preparing them for death. So

ORDINARY *of Newgate*, is one who is attendant in ordinary upon the condemned malefactors in that priſon, to prepare them for death; and he records the behaviour of ſuch perſons.

ORDINARY, or *Honourable Ordinary*, in *Heraldry*, a denomination given to certain charges properly belonging to that art.

The honourable ordinaries are by ſome writers reckoned *ten* in number; *viz.* the *chief*, *pale*, *bend*, *feſſe*, *bar*, *croſs*, *ſaltier*, *chevron*, *bordure*, and *orle*. See CHIEF, PALE, &c.

The heralds give ſeveral reaſons for their being called honourable: *viz.* 1. Their great antiquity, as having been uſed ever ſince armory was ſet on foot. And, 2. Becauſe they denote the ornaments moſt neceſſary for noble and generous men: thus the chief repreſents the helmet, wreath, or crown, covering the head; the pale repreſents his lance or ſpear;

ſpear; the bend and bar, his belt; the feſſe, his ſcarf; the croſs and ſaltier, his ſword; the chevron, his boots and ſpurs; and the bordure and orle, his coat of mail.

As to the allotting or diſtributing of theſe ordinaries, ſome authors write, that when a gentleman, having behaved himſelf gallantly in fight, was preſented to the prince, or general, and a ſuitable coat-armour ordered him; if he were wounded in the head, they gave him a chief; if in the legs he had a chevron; and if his ſword and armour were diſcoloured with the blood of the enemies, a croſs or bordure.

Some heralds have attempted to increaſe the number of honourable ordinaries to twenty; adding to thoſe above mentioned, the *plain quarter*, the *giron*, the *eſcutcheon*, *cappe* dexter and ſiniſter, *emmanch* dexter and ſiniſter, *chauſſe* dexter and ſiniſter, and the *point*. But theſe are not yet authoriſed.

Some writers diſtinguiſh ordinaries into *honourable* and *ſubordinate*. *Honourable* ordinaries, which are the principal charges in heraldry, they define as made of lines only; which, according to their diſpoſition and form, receive different names. Of theſe they reckon nine, *viz.* the *chief*, *pale*, *bend*, *bend ſiniſter*, *feſs*, *bar*, *chevron*, *croſs*, and *ſaltier*. The *ſubordinate* ordinaries are ancient heraldic figures, frequently uſed in coats of arms, and diſtinguiſhed by peculiar terms: theſe are the *giron*, *canton*, *fret*, *pile*, *orle*, *ineſcutcheon*, *treſſure*, *flanches*, *flaſques*, *voiders*, *loxenge*, *fuſil*, and *maſcle*.

Mr. Edmondſon reckons nineteen ordinaries; *viz.* *chief*, *pale*, *bend*, *feſs*, *bar*, *border*, *eſcutcheon*, *flaſque*, *flanch*, *voider*, *croſs*, *ſaltier*, *chevron*, *fret*, *pile*, *gyron*, *quarter*, *canton*, and *file* or *label*; which ſee reſpectively.

ORDINATE. See CO-ORDINATE.

ORDINATES, in *Geometry* and *Conics*, are lines drawn from any point of the circumference of an ellipſis, or other conic ſection, perpendicularly acroſs the axis, to the other ſide.

The Latins call them *ordinatim applicatæ*.

The halves of each of theſe are properly only *ſemi-ordinates*, though popularly called *ordinates*.

The ordinates of a curve may more generally be defined to be right lines parallel to one another, terminated by the curve, and biſected by a right line called the *diameter*. In curves of the ſecond order; if any two parallel right lines be drawn ſo as to meet the curve in three points; a right line which cuts theſe parallels ſo, as that the ſum of two parts terminating at the curve on one ſide the ſecant, is equal to the third part terminated at the curve on the other ſide; will cut all other right lines parallel to theſe, and that meet the curve in three points, after the ſame manner, *i. e.* ſo as that the ſum of the two parts on one ſide will always be equal to the third part on the other ſide. And theſe three parts, equal on either ſide, ſir Iſaac Newton calls *ordinatim applicatæ*, or ordinates of curves of the ſecond order. See CURVE.

ORDINATE *in a Parabola*, *Hyperbola*, and *Ellipſis*. See the reſpective articles.

ORDINATE *Ratio*, is that in which the antecedent of the firſt ratio is to its conſequent, as the antecedent of the ſecond is to its conſequent.

ORDINATION, the act of conferring holy orders; or of initiating a candidate into the diaconate, or prieſthood.

As to the qualification of the perſons to be ordained, ſee DEACON and PRIEST.

The form of ordination in the church of England is annexed to the book of Common Prayer, and the authority of it eſtabliſhed by 5 & 6 Edw. VI. c. 1. 8 Eliz. c. 1. by art. 36. of the thirty-nine articles, by the eighth canon, and alſo by the act of Uniformity, 13 & 14 Car II. c. 4. This act directs, that all ſubſcriptions to be made to the thirty-nine articles ſhall be conſtrued to extend (touching the 36th article above-mentioned), to the book containing the form and manner of making, ordaining, and conſecrating of biſhops, prieſts, and deacons in this act mentioned, as the ſame did heretofore extend unto the book ſet forth in the time of king Edward VI.

It is required, previouſly to ordination, by 1 Eliz. c. 1. and 1 W. c. 8. that every perſon taking orders, ſhall take the oaths of allegiance and ſupremacy before the ordinary or commiſſary: and by the 31 Eliz. c. 12. none ſhall be admitted to the order of deacon, or miniſtry, unleſs he ſhall firſt ſubſcribe to all the articles of religion agreed upon in convocation in the year 1562, which only concern the confeſſion of the true Chriſtian faith, and the doctrine of the ſacraments. By can. 36. no perſon ſhall be received into the miniſtry, except he ſhall firſt ſubſcribe to the following articles: 1. That the king's majeſty, under God, is the only ſupreme governor of this realm, and of all other his highneſs's dominions and countries, as well in all ſpiritual or eccleſiaſtical things or cauſes, as temporal; and that no foreign prince, perſon, prelate, ſtate or potentate hath, or ought to have, any juriſdiction, power, ſuperiority, preeminence or authority, eccleſiaſtical or ſpiritual, within his majeſty's ſaid realms, dominions and countries. 2. That the book of Common Prayer, and of ordering of biſhops, prieſts, and deacons, containeth in it nothing contrary to the word of God, and that it may lawfully be uſed, and that he himſelf will uſe the form in the ſaid book preſcribed in public prayer, and adminiſtration of the ſacraments, and none other. 3. That he alloweth the book of articles of religion agreed upon by the archbiſhops and biſhops of both provinces, and the whole clergy, in the convocation holden at London, in the year of our Lord God 1562; and that he acknowledgeth all and every the articles therein contained, being in number thirty-nine, beſides the ratification to be agreeable to the word of God. This ſubſcription is to be made before the biſhop himſelf. And for the avoiding all ambiguities, that perſon ſhall ſubſcribe in this form and order of words, ſetting down both his chriſtian and ſurname, *viz.* I N.N. do willingly and ex animo ſubſcribe to theſe three articles above-mentioned, and to all things that are contained in them. And if any biſhop ſhall ordain any, except he ſhall firſt have ſo ſubſcribed, he ſhall be ſuſpended from giving of orders for the ſpace of twelve months. By can. 31. the ordination, as well of deacons as miniſters, ſhall be performed in the time of divine ſervice, in the preſence not only of the archdeacon, but of the dean and two prebendaries at the leaſt, or (if by any lawful cauſe they ſhall happen to be let or hindered) in the preſence of four other grave perſons, being maſters of the arts at the leaſt, and allowed for public preachers. In practice a leſs number than is required, either by the ſtat. 21 Hen. VIII. c. 13. or by the foreſaid canon, is ſometimes admitted; by virtue, as it is ſaid, of the rubric in the office of ordination, which directeth, "that the biſhops with the prieſts preſent ſhall lay their hands upon the perſons to be ordained;" implying, as is ſuppoſed, that if there are but two prieſts preſent, it ſufficeth by this rubric, which is eſtabliſhed by the act of parliament of the 13 & 14 C. 2. For other particulars, ſee the form of ordination already cited, and the articles DEACON and PRIEST.

The council of Rome, in 744, orders that no ordinations ſhall be held except on the firſt, fourth, ſeventh, and tenth

tenth months. With us, by can. 31, ordination days are the four Sundays immediately following the Ember weeks; being the ſecond Sunday in Lent, Trinity Sunday, and the Sundays following the firſt Wedneſday after September the 14th, and December the 13th.

The ordination of biſhops is more properly called *conſecration*; which ſee.

Ordination has always been eſteemed the principal prerogative of biſhops; and they ſtill retain the function as a kind of mark of ſpiritual ſovereignty in their dioceſes.

In the ancient diſcipline, there was no ſuch thing as a vague, and abſolute ordination; but every one was to have a church, of which he was to be ordained clerk, or prieſt. In the twelfth century they grew more remiſs, and ordained without any title or benefice.

The council of Trent reſtored the ancient diſcipline, and appointed, that none ſhould be ordained but thoſe who were provided of a benefice ſufficient to ſubſiſt them. The ſhadow of which practice ſtill obtains among us.

The reformed hold the call of the people the only thing eſſential to the validity of the miniſtry; and teach, that ordination is only a ceremony, which renders the call more auguſt and authentic.

Accordingly the Proteſtant churches of Scotland, France, Holland, Switzerland, Germany, Poland, Hungary, Denmark, &c. have no epiſcopal ordination. For Lucher, Calvin, Bucer, Melancthon, &c. and all the firſt reformers and founders of theſe churches, who ordained miniſters among them, were themſelves preſbyters, and no other. And though in ſome of theſe churches there are miniſters called ſuperintendants, or biſhops, yet theſe are only *primi inter pares*, the firſt among equals; not pretending to any ſuperiority of orders. Having themſelves no other orders than what either preſbyters gave them, or what was given them as preſbyters, they can convey no other to thoſe they ordain. On this ground the Proteſtant diſſenters plead that their ordination, though not epiſcopal, is the ſame with that of all the illuſtrious Proteſtant churches abroad; and object, that a prieſt ordained by a Popiſh biſhop, ſhould be received into the church of England as a valid miniſter, rightfully ordained; whilſt the orders of another, ordained by the moſt learned, religious preſbyter, which any foreign country can boaſt, are pronounced not valid, and he is required to ſubmit to be ordained afreſh.

In oppoſition to epiſcopal ordination, they urge, that Timothy was ordained by the laying on of the hands of the preſbytery (1 Tim. iv. 14.), that Paul and Barnabas were ordained by certain prophets and teachers in the church of Antioch, and not by any biſhop preſiding in that city (Acts xiii. 1, 2, 3.), and that it is a well known fact, that preſbyters in the church of Alexandria, ordained even their own biſhops for more than two hundred years in the earlieſt ages of Chriſtianity. They farther argue, that biſhops and preſbyters are in ſcripture the ſame; and not denominations of diſtinct orders or offices in the church: referring to Philip. i. 1. Tit. i. 5. 7. Acts, xx. 27, 28. and 1 Pet. v. 1, 2. To the ſame purpoſe they maintain, that the ſuperiority of biſhops to preſbyters is not pretended to be of divine but of human inſtitution, not grounded on ſcripture, but only upon the cuſtom or ordinances of this realm, by the firſt reformers and founders of the church of England, nor by many of its moſt learned and eminent doctors ſince. See Stillingfleet's Irenic. chap. 8. p. 385. in which the learned author affirms and ſhews this to be the ſentiment of Cranmer, and other chief reformers both in Edward VI. and queen Elizabeth's reign, of archbiſhop Whitgift, biſhop Bridges, Loe, Hooker, Sutcliff, Hales, Chillingworth, &c. Moreover, the book intitled the "Inſtitution of a Chriſtian Man," ſubſcribed by the clergy in convocation, and confirmed by parliament, owns biſhops and preſbyters by ſcripture to be the ſame. Beſides, the Proteſtant diſſenters allege, that if epiſcopal ordination be really neceſſary to conſtitute a valid miniſter, it does not ſeem to be enjoined by the conſtitution of the church of England: becauſe the power of ordination which the biſhops exerciſe in this kingdom, is derived entirely and only from the civil magiſtrate; and he authoritatively preſcribes how, and to whom ordination is to be given: that if an ordination ſhould be conducted in other manner and form than that preſcribed by him, ſuch ordination would be illegal, and of no authority in the church. Accordingly the biſhop at the ordination of the candidate aſks, Are you called according to the will of our Lord Jeſus Chriſt, and the due order of this realm? The conſtitution and law of England ſeem to know nothing of uninterrupted lineal deſcent, but conſiders the king, veſted (by act of parliament or the ſuffrage of the people) with a fullneſs of all power eccleſiaſtical in theſe realms, as empowering and authoriſing biſhops to ordain: and this power of ordination was once delegated to Cromwell, a layman, as vicegerent to the king. They farther think it ſtrange, that the validity of orders and miniſtrations ſhould be derived, as ſome have contended, from a ſucceſſion of Popiſh biſhops; biſhops of a church, which, by the definition of the nineteenth article of the church can be no part of the true viſible church of Chriſt, and biſhops, likewiſe, who conſider the Proteſtant clergy, although ordained by Proteſtant biſhops, as mere common unconſecrated laymen. They object alſo to that ſubſcription, which is the term of ordination in the church of England. See Towgood's Diſſent from the Church of England fully juſtified, &c. edit. 5. 1779, p. 196, &c.

Pope Alexander II. condemns ordination *per ſaltum*, as they call it; *i. e.* the leaping to a ſuperior order without paſſing through the inferior.

Ordination is one of the ſacraments of the church of Rome.

ORDINE, order, arrangement; or the combination of many diſtinct things to make a whole. The term is uſed by the Italians in ſpeaking of the muſic of the ancients for ſyſtem: as *ordine di Mercurio, di Terpandro, di Filitao, di Pitagoro*, &c. to mark the order in which each of theſe authors arranged the ſounds, in their ſeveral ſyſtems, their number, and what diſtance and proportion they gave them; and they ſay of a tetrachord, that it is in *ordine di quattro corde:* that is, entirely compoſed of, and diviſible by, four ſtrings or ſounds. See TETRACHORD.

ORDINGEN, in *Geography*. See URDENGEN.

ORDNANCE. See ORDINANCE.

ORDORF, in *Geography*, a town of Saxony, in Thuringia; 10 miles S. of Gotha.

ORDONNANCE, or ORDINANCE, in *Painting*, denotes the diſpoſition of the parts of a picture either with regard to the whole piece, or to the ſeveral parts; as the groups, maſſes, contraſts, aſpects, &c.

In the ordonnance there are three things regarded; *viz.* the place, or ſcene, where; the diſtribution, how; and the contraſt.

In the firſt, regard is to be had to the diſpoſition of things to ſerve as a ground-work; and to the plan, or poſition of bodies: under the former of which come, 1. The *landſcape*; whether an uninhabited place, where there is full liberty of repreſenting all the extravagancies of nature; or inhabited, where the marks of cultivation, &c. muſt be exhibited.

2. The *building*, whether ruſtic; in which the painter's

fancy is at liberty: or regular; in which a nice attention is required to the orders.

3. The mixture of both; in which it is a maxim to compoſe in great pieces, and make the ground-plot big enough, to neglect ſome little places, in order to beſtow more on the whole maſs, and to ſhew the more conſiderable places with the more advantage; and to mark ſome agitation in all the things that move.

As to the *plans* of bodies, they are either ſolid; which, again, are either ſo by nature, and which muſt be proportioned to their places; or artificial, where regard is to be had to the rules of geometry, perſpective, architecture, &c. Or they move: which they do, either by a voluntary motion, in which care muſt be had to proportion them to their ſituation, and to ſtrengthen them by regarding the equilibrium; or by ſome extraordinary power, as machines, &c. where the cauſes of their motions muſt appear. Or they are things at a diſtance. In all which an even plane muſt ſtill be propoſed to find their preciſe ſituation, and ſettle their place by ſudden breaks and diſtances agreeable to perſpective.

In placing the figures, regard muſt be had, 1. To the *group*, which connects the ſubject, and ſtays the ſight. In this are to be conſidered the knot or nodus, which binds the group; and the nearneſs of figures, which we may call the chain, as it holds them together; that the group be ſuſtained by ſomething looſe and diſtinct from it; and by the ſame joined and continued to the other groups: and that the lights and ſhadows be ſo diſpoſed, as that we may at once ſee the effect of all the parts of the compoſition.

2. To the *actions*, in which forced attitudes are to be avoided, and ſimple nature ſhewn in her moſt advantageous poſture. In weak and lean figures, the nudities are not to be ſhewn; but occaſions of covering them are to be ſought. In all human figures, ſpecial care to be taken, the head be well placed between the ſhoulders; the trunk on the haunches; and the whole on the feet.

3. To the *drapery*; which is to be adjuſted, ſo as it may appear real garments, and not ſtuffs looſely thrown on. The folds to be ſo diſpoſed as to leave the great parts, in which the nudity may appear, free; ranging the little folds about the joints, and avoiding them on the relievo of the members. And, laſtly, to diſpoſe the draperies, by raiſing the ſtuff, and letting it fall eaſily and lightly, that the air, ſuſtaining the folds, may let them fall ſoft.

Laſtly, in the *contraſt*, are to be conſidered the actions, which vary infinitely: the aſpects, which in actions of the ſame kind, may, by their difference, make a contraſt: the ſituation, according as they meet above or under the ſight, far or near. And, laſtly, cuſtom; which extends, indeed, to all parts of painting, but is particularly to be regarded in the ordonnance; to be managed diſcreetly, however, and ſtiffneſs and formality avoided.

ORDONNANCE, in *Architecture*, is nearly the ſame as in painting; *viz.* the compoſition of a building, and the diſpoſition of its parts, both with regard to the whole, and to one another.

Vitruvius defines ordonnance to be that which regulates the ſize or magnitude of all the parts of a building with reſpect to their uſe.

This definition is cenſured by M. Perrault, who takes the ordonnance to conſiſt in the diviſion of the plan or ſpot of ground on which the building is to be raiſed; *i. e.* in the apportioning or laying it out, agreeable to the intended dimenſions of the whole fabric; which Mr. Evelyn expreſſes in fewer words, by "determining the meaſure or what is aſſigned to compoſe the ſeveral apartments."

On this foundation, ordonnance is the judicious contrivance of the plan or model; as when the court, hall, lodgings, &c. are neither too large, nor too little: but the court, *v. gr.* affords convenient light to the apartments about it, and is large enough for uſual acceſs. The hall of fit capacity to receive company; the bed-chambers accordingly, &c. When theſe diviſions are either too great or too ſmall, with reſpect to the place, as a large court to a little houſe, or a little chamber, in a magnificent palace; the fault is in the ordonnance.

This the ancients called *taxis*; and diſtinguiſhed it from *diatheſis*, diſpoſition; which is, where all the parts and members of a building are aſſigned their juſt places and ſituation with regard to their quality, office, rank, &c. without any regard to the dimenſions, or quantity: as, that the veſtibule or porch be before the hall, the hall before the parlour, and that before the withdrawing-room, &c. The bed-chambers, again, to look to the ſun-riſing; and libraries, galleries of paintings, and cabinets of curioſities, &c. to the north.

ORDOVICES, in *Ancient Geography*, inhabitants of that country which is now called North Wales, and contains the counties of Montgomery, Merioneth, Carnarvon, Denbigh and Flint. Theſe Ordovices, or as Tacitus calls them, Ordeuices, are ſuppoſed to have been originally of the ſame tribe or nation with the Huicii of Warwickſhire, who were under ſome kind of ſubjection to the Cornavii; but the Huicii of North Wales, being a free and independent people, were called Ordh-Huici, or the free Huici. When they were invaded by the Romans, they ſhewed a ſpirit worthy of their name, and fought with great bravery in defence of their freedom and independence. Though they ſuſtained a great defeat from the Roman general Oſtorius, in conjunction with the Silures, they maintained the war for a conſiderable time, until they were finally ſubdued, with great ſlaughter, by the renowned Agricola. It was partially owing to the nature of the country, and to the vicinity of Diva, now Cheſter, where a whole legion was quartered, that the Romans had ſo few towns or ſtations in the territories of the Ordovices. Mediolanium was the capital of the nation, and was probably ſituated at Maywood or Meifad in Montgomeryſhire. In the time of the Romans this was a place of ſome note, but it was afterwards quite demoliſhed by Edwin, king of Northumberland. Beſides this, the Romans had a ſmall number of other towns in this country; as Segontium now Carnarvon, Conovium now Conway, and Varæ now Bodvary, all mentioned in the 11th journey of Antoninus. The country of the Ordovices was comprehended in the Roman province, which was called Britannia Secunda.

ORDUNA, in *Geography*, a ſmall town of Spain, in the province of Biſcay; ſituated to the S. of Bilbao, in a pleaſant valley, encompaſſed on all ſides by high and ſteep mountains. It has two pariſh churches, a convent of monks, and another of nuns. The interior cuſtom-houſe of Biſcay is eſtabliſhed here; but it only collects the duties upon merchandize imported into Caſtile; 42 miles S.W. of St. Sebaſtian. N. lat. 42° 56′. W. long. 2° 57′.

ORE, a town of Sweden, in Dalecarlia; 60 miles N.N.W. of Fahlun.

ORES, in *Mineralogy* and *Metallurgy*, ſignify thoſe mineral ſubſtances found in the earth, from which metals are procured. The ores of moſt of the metals conſiſt of the metal combined with ſome other ſubſtance, and the proceſs by which the metal is ſeparated from the combined matter, is termed the reduction of the ore. We ſhall not here enumerate the ores of the different metals, as they are amply treated of under the reſpective metals.

Aſſay and Analyſis.—This branch of operative chemiſtry is

is divided into two parts, the one called the humid, and the other the dry analyſis. By the firſt of theſe, the ſubſtance is diſſolved in acids or alkalies, and the different conſtituents ſeparated by different re-agents. The dry proceſs conſiſts in firſt expoſing the ore to a red heat, for the purpoſe of ſeparating its volatile parts. The remainder is then treated with certain fluxes and inflammable matter, to ſeparate the metal which is found in a rounded form, at the bottom of the crucible, and hence is called a button.

A little reflection will make it clear, that the humid analyſis ſhould always precede that of the dry. In order to know the nature of the particular flux to be employed after its ore has been roaſted and its volatile products aſcertained, it may be ſubjected to the action of ſome acid, and firſt the muriatic. If this has no action upon it, try the nitric; ſhould this acid not diſſolve the whole, try the nitro-muriatic, which may conſiſt of equal parts of the two acids. If the whole is not diſſolved by this, it may be preſumed that the ore contains flint, or ſome ſalt not decompoſable by the above acids. Under either of theſe circumſtances it is proper to fuſe the ore with pure potaſh, in a ſilver crucible. The fuſed maſs will be of a dark green if iron be preſent, of a graſs green if the ore contain copper, blue with cobalt, yellow with lead, and purple with manganeſe. This maſs being boiled for ſome time with diſtilled water, till all the ſoluble matter is taken up, muſt now be treated with nitric acid. It is probable that all, except the ſilex, will be diſſolved in the acid. From this acid ſolution, with the different liſts, it muſt be aſcertained what are the conſtituents of the ore, and afterwards the different ſubſtances muſt be ſeparated with a view to determine their proportions. See under the different metals *Aſſay and Analyſis*.

When the nature and proportions of the different ſubſtances combined with the metal conſtituting the ore are made out, the next thing is to expoſe it in a crucible, with ſuch ſubſtances as will combine with the matter to be ſeparated, the compounds either becoming fuſible or being ſeparated in the form of gas. For inſtance, in the ſmelting of iron ores of the argillaceous kind, lime is uſed in order to form a fuſible compound with the alumine, and charcoal or coak in order to form carbonic acid with the oxygen of the oxyd of iron. If the ore contain ſilex, potaſh or ſoda ſhould be uſed in order to form glaſs, which is greatly more fuſible than the earth would have been with the metallic oxyd alone. Borax is frequently employed as a flux from its great facility of combining with the ſilex and other earths. See STONES, *Analyſis of*.

ORES, *Dreſſing*, or *Waſhing of*, is the preparing them as they come rough from the mine, for the working by fire. This is done ſeveral ways in different countries, and in reſpect to the different ores of the metals. In Devonſhire we have a very eaſy method, which is ſo expeditious, and ſo good for all the purpoſes, that it is worthy of imitation in other places. After the ore is dug, it is toſſed up by hand from ſhamble to ſhamble by the ſhovel-men in the mine, and drawn up in buckets by a winch at the top of the ſhaft. As ſoon as the whole quantity for one dreſſing is brought up, the large ſtones are broken, and the whole is then carried to the mills, where one horſe turns a wheel that moves the machines for powdering a great quantity of it: theſe are called the ſtamping or knocking mills. The ore is unloaded at the head of the paſs or entrance into theſe mills: this paſs is made of two or three bottom-boards and two ſide-boards, in form of a hollow trough, and ſtands in a ſlanting direction. The ore by its own weight is carried down this trough, and lodges itſelf in the coffer. The coffer is a long ſquare box, made of the firmeſt timber, and of three feet long, and a foot and half broad. The ore is not ſuffered to fall into this all at once, but is ſtopped over the mouth of the trough by a croſs board, where a cock turns in a quantity of water at the ſame time, which waſhes down juſt as much of the ore with it into the trough, as there ought to be. In this coffer there are three lifters placed between two ſtrong board-leaves, having two braces or thwart-pieces on each ſide to keep them ſteady, as a frame with ſtamp-heads. Theſe heads are of iron, and weigh about thirty or forty pounds a-piece, and ſerve to the breaking of the lumps of ore in the coffer.

The lifters are about eight feet long, and half a foot ſquare. They are always made of heart of oak, and have as many in-timbers or guiders between them: they are lifted up in order, by a double number of tappets, which are faſtened to as many arms paſſing diametrically through the great beam, which is either turned by the wheel and horſe, or, where there is a conveniency of water, by an overſhot water-wheel on two boulſters. The tappets exactly but eaſily meet with the tongues, which are ſo placed in the lifters, as that they eaſily ſlide from each other, and ſuffer the lifters to fall with great force on the ore in the trough. The frequent pounding of theſe ſoon reduces the large maſſes into a ſort of ſand, which is waſhed out of the trough by the continual current of the water from the cock through a braſs-grate, which is placed at one end of the coffer between two iron bars. This operation is called by the miners *bricking*, or brick-working the ore. See BUDDLE.

The powdered ore is conveyed out of the trough into the *launder*, which is a trench cut in the floor of eight feet long, and ten feet over. This is ſtopped at the lower end with turf, ſo that the water is all ſuffered to paſs away, and the powder of the ore is ſtopped. Thus the launder by degrees fills up with the dreſſed ore, and this is removed out with ſhovels, as occaſion requires. The launder is divided into three parts, the forehead, the middle, and the tail: that ore which lies in the forehead, that is, within a foot and a half of the grate, is always the richeſt and beſt, and is laid up in a heap by itſelf; the middle and tail afford a poorer one, and theſe are ſometimes laid up in ſeparate heaps; ſometimes thrown in one heap together.

ORES, *Eſſaying*, or *Aſſaying of*. See ASSAY, ORE ſupra, and the following references. See alſo Cramer's Art of Aſſaying.

ORES *of Antimony*, *Arſenic*, *Biſmuth*, *Cobalt*, *Copper*, *Gold*, *Iron*, *Lead*, *Mercury*, *Platina*, *Silver*, *Tin*, *Zinc*. See the ſeveral articles.

ORES, *Smelting of*. See SMELTING.

ORE-*Weed*, in *Agriculture*, a general name for weeds growing at the bottom of the ſea, and alſo on the muddy and rocky parts of the ſhore. Theſe ſorts of ſea-weeds form ſo beneficial a manure, that farmers ought not to grudge the expence of carrying them a few miles. It is a practice in Devonſhire, Cornwall, and ſome other maritime parts of England, to have theſe weeds laid in heaps till they are rotten, and then ſpread upon the land, about a load to three rods. But this laſts only one year, unleſs ſand, or a ſtiff earth, according to the quality of the ſoil intended to be improved, be laid on or mixed with them; and then they become a laſting manure. In ſome places, theſe weeds are gathered in heaps, and burnt as ſoon as they are dry: after which, about a buſhel of their aſhes is laid upon three rods of ground. But theſe, like all other aſhes, ſhould be mixed with ſand, or ſtiff earth, in order to have the land left good: otherwiſe they are only an improvement for a year. Theſe aſhes are particularly good for graſs-grounds over-run with moſs. Looſe ſandy ſoils are likewiſe peculiarly benefited by

by this weed; but being a ſubmarine plant, the wind and ſoil ſoon exhale its moiſture; ſo that the more ſpeedily it is taken from the ſhore, where ſtorms often throw it up in great quantities, the better it is. When ſpread on the ground, and afterwards covered over, it ſoon diſſolves into a ſaline, mucilaginous, ſlimy matter, proper to fertilize and bind light ſoils. This is the moſt approved way of applying it; though ſome lay it naked and freſh from the ſea, upon their barley land, towards the end of March and beginning of April, and have a good crop of corn: but ſuch quantities of rank weeds are apt to ſhoot up afterwards, that no wholeſome plant is to be expected that year.

It may be noticed, that the value of the lands on ſome of the coaſts of Scotland has been more than doubled by the uſe of this excellent manure. It is chiefly uſed there for barley; and the farmers watch every opportunity, when it is thrown in by the ſea, and lay it on at all ſeaſons, in autumn, winter, and ſpring. But if they could chooſe their time, it would probably do beſt about the month of March; for being then ploughed into the ground, and afterwards ploughed up again to the ſeed, it would be better incorporated and blended with the ſoil: whereas, if it be laid on in autumn, before the fallowing or firſt ploughing, it is too much waſted before the ſpring; and if it be laid on the ſeed furrow, it is apt to burn the ground in a dry ſeaſon, though it will do very well in this method in a wet ſummer. Its effects are but juſt felt the ſecond year; though it is laid on thicker upon ſtrong clay land, which receives no other manure for three crops, *viz.* barley, oats, peaſe and beans; a method which might perhaps be altered for the better, by omitting the oats, and ſowing alternately barley, and peaſe and beans, and laying on the ſea-ware, as theſe weeds are commonly called, for every ſecond crop of peaſe and beans.

It would ſeem clear, from Mr. Scott's account of the manner of uſing the ſea-ware in Scotland, as publiſhed by Mr. Maxwell, that much of this valuable manure muſt neceſſarily be loſt through want of proper management, as they have no reſervoirs to keep it in, when thrown aſhore at a ſeaſon in which they cannot uſe it, or where there is no ground in tilth, as is generally the caſe in winter, and during the buſy part of their hay and corn harveſt. It ſhould be collected on theſe occaſions, and lodged in a place free from any running water; and as it is equally beneficial to ſtrong or light lands, it might be there covered with ſand or clay, according to the nature of the ſoil for which it is intended. This will prevent its being parched by the ſun, or its diſſolving into a putrid maſs, which, if not ſecured in this manner, would either be waſhed away by rains, or fly off into the air: whereas, when thus covered, it would greatly enrich the clay or ſand, and render them good manures for their oppoſite ſoils. If it be thrown aſhore at a time when it can be ploughed in directly, that is ſuppoſed the beſt manner of uſing it.

It is ſtated, that there is a kind of land all along the coaſt, which is gravelly, and covered over ſo thick with ſea-ſtones, that, to look at it, one would not think corn could ſpring through them; and another ſort of land, which is a deadiſh ſand. To both theſe grounds ſea-ware is the only manure; for dung of all kinds has been often tried, but with no ſucceſs; and yet ſea-ware makes them bring excellent crops of barley. This kind of ground is ſeldom ploughed more than twice, and the ſea-weed is generally laid on before the firſt ploughing. Barley is ſowed during two years, and peaſe the third; a freſh manure of ſea-weed being laid on each year that barley is ſown. As little wheat is cultivated in ſome parts, the farmers there might probably improve their practice of raiſing barley and peaſe, by ſowing them alternately, and laying the ſea-ware to the peaſe. In the ſummer it is carried to a diſtance from the ſea, and laid upon ley-ground, (arable land under graſs,) which, though in very ill heart, will bear a good crop of oats with only once ploughing, or of barley, if ploughed again in the ſpring.

But another kind of ſea-ware, of a much ſtronger nature than that which is thrown up by the waves, is cut from the rocks at low water, and will laſt three years. It coſts more labour, but brings greater recompence. The beſt time of laying this on the ground is ſuppoſed to be in autumn, before the land is ploughed rough for a ſpring crop. It is ſaid that the farmers on the coaſts of Scotland prefer this manure to any other, eſpecially for their light grounds; and it has the advantage of being much more eaſily tranſported, becauſe one load of it will go as far as two of dung. It does very well in kitchen gardens, where Mr. Scott has ſeen pot-herbs and roots of an extraordinary ſize produced by its help; and he has known fruit-trees, perfectly barren before, rendered extremely fruitful by laying this manure about the roots. See SEA-*Weed* and MANURE.

OREBRO, in *Geography*, a town of Sweden, the capital of the province of Nericia, or Nerike, ſituated near the weſtern extremity of the lake Hielmar. Upon a ſmall iſland in the centre, formed by two branches of the Swart, ſtands the caſtle, which was formerly a royal reſidence, and is now appropriated to the governor of the province. The inhabitants ſend iron, vitriol, and red paint to Stockholm; and the trade with that capital acroſs the Hielmar and Mæler, by means of the canal of Arboga, is very conſiderable. The town poſſeſſes manufactories of fire-arms, cloth, and tapeſtry; 88 miles W. of Stockholm. N. lat. 59° 15′. E. long. 15° 4′.

OREBY-BUS, a town of Sweden, in Weſtmanland; 20 miles N. of Upſal.

ORECHOVITZ, a town of European Turkey, in Bulgaria; 28 miles W.S.W. of Nicopoli.

OREDESCH, a river of Ruſſia, which runs into the Luga; 16 miles N. of Luga.

OREEHOUA, one of the ſmaller Sandwich iſlands, being a ſingle high hummock, joined by a reef of coral rocks to the northern extremity of Oneeheow. The number of inhabitants is ſtated by captain King, in Cook's third Voyage, vol. iii. at 4000. N. lat. 22° 2′. E. long. 199° 52′.

OREGAN, or *River of the Weſt*, a river of North America, which runs into the Pacific ocean, N. lat. 43° 18′.

OREGIUS, AUGUSTINE, in *Biography*, a learned Italian cardinal and philoſopher, was born of parents in humble circumſtances at Florence, in the year 1577. At a very early age he afforded ſtriking indications of good natural abilities, and a great love of learning, and met with friends who ſent him to purſue his ſtudies at Rome. Here an adventure occurred to him, ſimilar to that which befel the youthful Joſeph, in the houſe of his Egyptian maſter, and he proved equally faithful to his duty. When cardinal Bellarmine was apprized of this fact, he took the young man under his particular patronage, and placed him in a college, where the young men of the principal families in Rome were educated. He improved the advantages of his ſituation with the greateſt diligence and ſucceſs, and became a proficient in the Greek tongue, in philoſophy, and in ſeveral other branches of literature. Little is related with reſpect to the perſonal hiſtory of Oregius; but he appears to have entered into orders, and to have reſided at firſt with cardinal Bellarmine, and afterwards with Barberini, who became pope by the name of Urban VIII. While the cardinal Barberini was

legate at Bologna, he employed Oregius to examine whether Ariſtotle taught the mortality of the ſoul, with the intention, ſhould that be the caſe, of perſuading the pope to prohibit his works as far as regarded that ſubject. On this occaſion he vindicated Ariſtotle in a piece, entitled "Ariſtotelis vera de rationalis Animæ Immortalitate Sententia," which was publiſhed at Rome in 1631. He publiſhed other theological pieces about the ſame time. Upon the acceſſion of Urban VIII. to the papal dignity, he made Oregius his divine, and in 1634 raiſed him to the purple, and preſented him to the archiepiſcopal ſee of Benevento. He died in the following year. He was author of a work "De Angelis," and another "De Operibus ſex Dierum," which were printed at Rome in 1632. His works were collected and printed in a folio volume, in 1637. Bayle. Moreri.

OREGRUND, or OEREGRUND, in *Geography*, a ſea-port town of Sweden, in the province of Upland, ſituated on the ſea-coaſt, and built in 1491 by ſome inhabitants of Oeſthammer, who left that town becauſe of the great decreaſe of water in the harbours, which entirely ruined its trade. Oregrund was a ſtaple town till the year 1630, and has been three times burnt and quite demoliſhed by the Ruſſians. The harbour is defended from the violence of the ſea by a mole; 34 miles N.N.E. of Upſal. N. lat. 60° 20′. E. long. 18° 15′.

OREILLARD, in the *Manege*. See WIDE-*Eared*.

OREILLE, Fr., *Orecchio*, Ital., the ear. This word, ſays Rouſſeau, is uſed figuratively as a muſical term. To have an ear, is ſaid of a perſon fond of muſic, whoſe auricular organ is well conſtructed, ſenſible, nice, and juſt in judging of the perfections and imperfections of muſical tones, whether as to tune or time. With a bad or falſe ear, a ſinger neither ſings in tune, nor can judge accurately of the intonations of others; and when inſenſible to the preciſion of meaſure, the time is broken and changed perpetually, without knowing it.

Thus, the word *ear* is always uſed for a diſcriminating quickneſs and delicacy in the ſenſe of liſtening or hearing muſical tones. See EAR.

OREL, in *Geography*, a town of Ruſſia, and capital of the government of Orlovſkoe, on the Oka; 176 miles S.S.W. of Moſcow. N. lat. 52° 56′. E. long. 36°.

ORELIA, in *Botany*. See ALLAMANDA.

ORELLANA, FRANCIS, in *Biography*, a Spaniſh adventurer, celebrated as the firſt European navigator of the river Maragnon, was a young officer, ſecond in command to Gonzalo Pizarro, in an expedition undertaken in 1540, from Quito in Peru, for the diſcovery of the inland country to the eaſt of the Andes. The party had reached the banks of the Coca, a large river which diſcharges itſelf into the Maragnon, or Maranon, when they built a bark of green wood, for the purpoſe of aſſiſting their progreſs, and manned it with fifty ſoldiers, under the command of Orellana. He embarked in February 1541, and committed himſelf to the current without compaſs or pilot, and actually reached the ocean in about ſeven months. He got ſafe to Cubagua, whence he ſailed to Spain. (See AMAZON, AMAZONIA, and MARANON.) Ten years after this, he was entruſted with the command of three veſſels from Spain, with which he periſhed, without having been able to diſcover the true mouth of the river, which he had before navigated, and which is ſometimes now called by his name, as by the author of the Seaſons:

"Swell'd by a thouſand ſtreams, impetuous hurl'd
From all the roaring Andes, huge deſcends
The mighty Orellana."

ORELLANA, in *Botany*. See BIXA.

ORELLANA, in *Geography*, a town of Spain, in the province of Eſtramadura, on the Guadiana; 24 miles E. of Merida.

ORENBURG, a town of Ruſſia, and capital of a province, to which it gives name, in the government of Upha, on the Ural. This town with its fortreſs was built in 1738, by order of the empreſs Ann, at the conflux of the Or and Ural; but the ſituation being found inconvenient, the inhabitants were removed to a new town built lower down on the Ural in 1749: ſince the eſtabliſhment of a conſiderable commerce here, all Ruſſian and Aſiatic merchants are permitted, on paying a certain duty, to ſell their goods by wholeſale or retail; and all European merchants are allowed to bring their goods from the harbours and frontier towns to Orenburg; 180 miles S. of Upha. N. lat. 51° 42′. E. long. 55° 14′.

ORENSE, AURIA, or *Aquæ Calidæ*, a city of Spain, in Galicia, ſo ranked as the ſee of a biſhop, ſituated at the foot of a mountain, upon the left bank of the Minho. In the time of the Gothic princes, the biſhop was ſuffragan to the archbiſhop of Braga in Portugal; but after the invaſion of the Moors, he became dependent on the archbiſhop of Compoſtella. Its hot ſprings were famous in ancient times; whence it obtained the name of "Aquæ Calidæ;" and it is ſaid that they have an effect on the temperature of part of the town, and the adjacent country. The town is ſmall, but airy and tolerably well built; its ſtreets are ſtraight, and its ſquares regular. It has a cathedral and pariſh church, and a chapter, the members of which are numerous. Here are alſo two convents of monks; one that belonged to the ancient Jeſuits; two chapels; a houſe of inſtruction for girls; an hoſpital for the ſick poor; and an aſylum. The population is calculated at 2300 perſons. Here is a remarkable bridge of one arch, ſo lofty that a ſhip can paſs under it. The plain of Orenſe is beautiful, pleaſant, and fertile, abounding with excellent grapes and good fruits; 37 miles S.E. of Compoſtella. . lat. 42° 25′. W. long. 7° 53′.

OREO, a town of the iſland of Negropont; 44 miles N.N.W. of Negropont. N. lat. 39° 7′. E. long. 23° 18′.

OREOBOLUS, in *Botany*, from ορος, *a mountain*, and βωλος, *a maſs*, *lump*, or *clod*, alluding to its place and form of growth. Brown Prodr. Nov. Holl. v. 1. 235. Claſs and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juſſ. *Cyperaceæ*, Br.

Eſſ. Ch. Glumes two, ſpathaceous, deciduous, including one floret, ſometimes accompanied by an inner ſcale. Corolla (perianth of Brown) in ſix deep ſegments, cartilaginous, remaining after the fall of the fruit. Style deciduous. Stigmas three. Nut cruſtaceous.

1. O. *Pumilio*. Gathered by Mr. Brown in Van Diemen's land. A dwarf plant, forming broad, denſe, convex tufts, on the ſummits of the mountains. *Stems* divided in the lower part, denſely clothed with imbricated, ſtraight, ſheathing, ribbed, ſpreading, linear *leaves*, dilated at their baſe. *Stalks* axillary, ſhort, compreſſed, ſingle-flowered. The *glumes* compoſe a two-valved two-edged ſheath.

OREOCALLIS, ſo named by Mr. Brown, from ορος, *a mountain*, and καλος, *beautiful*. Brown Tr. of Linn. Soc. v. 10. 196. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juſſ.

Eſſ. Ch. Corolla irregular, ſplit on one ſide, four-toothed. Stamens ſunk in the concave tips of the corolla. Nectariferous gland none. Germen ſtalked. Stigma oblique, orbicular, dilated, rather concave. Follicle cylindrical. Seeds numerous, with a terminal wing.

1. O. *grandiflora*. Embothrium grandiflorum; Lamarck Dict. v. 2. 354. Willd. Sp. Pl. v. 1. 538. (E. emarginatum; Ruiz and Pavon Fl. Peruv. v. 1. 62. t. 95.)—Native of the colder mountains of Peru. A perfectly ſmooth *ſhrub*, twelve feet high. *Stem* erect, branched, the branches round, granulated. *Leaves* ſcattered, ſtalked, elliptic-oblong, four inches in length, coriaceous, ſlightly revolute, entire, emarginate, with a minute point, ſingle-ribbed, with many tranſverſe veins. *Cluſters* terminal, ſolitary, erect, denſe, of numerous roſe-coloured *flowers* in pairs, each pair with a minute *bractea* at the baſe of their partial ſtalks, but no general *involucrum*. This ſplendid plant flowers in September and October, when it is uſed to ornament the temples and idols of the Peruvians. Its habit is altogether like that of the *Embothrium coccineum* of Forſter and Linnæus, and of the *E. ſpecioſiſſimum* of Smith, New Holl. Bot. t. 7. Sims in Curt. Mag. t. 1128. We preſume to think there ought to be no generical diſunion of theſe plants, though the preſent wants the nectariferous gland beneath the germen, which the others have. The *ſtigma* indeed, which is vertical and club-ſhaped in *Embothrium*, ſeems a moſt important mark.

OREON, a name given by the ancients to a kind of horſe tail which they found growing on the mountains in wet and damp places. It is to this ſpecies that many authors have attributed the principal virtues of the genus; and this ſeems to have been the ſame with our great water horſe-tail. Neophytus ſays, that it roſe up with a ſingle ſtalk reſembling a young reed, and that this was compoſed of ſeveral joints, which, in the manner of cups, were inſerted one into another; and that from theſe joints the leaves grew, and that they reſembled thoſe of the pine-tree. The branches are what this author calls leaves, and they do pretty well reſemble the leaves of the pine-tree. They are long and ſlender, and of a bright green. Our great horſe-tail loves the heads of ſprings in hilly countries, and is always moſt plentiful in ſuch places.

OREOSELINUM. See ATHAMANTA.

ORES, in *Geography*, a town of the iſland of Sardinia; 16 miles S S.E. of Oreſtagni.

ORESA, a town of Lithuania, in the palatinate of Novgorod; 18 miles E.N.E. of Sluck.

ORESME, NICHOLAS, in *Biography*, an eminent French prelate, and one of the moſt celebrated writers in the 14th century, was born at Caen in Normandy. He purſued his ſtudies at the univerſity of Paris, where he entered himſelf a member of the college of Navarre, and was in due time admitted to the degree of doctor by the faculty of the Sorbonne. In 1355, he was elected grand maſter of the college in which he was educated; and Mr. Launoy ſays that he greatly contributed to the revival of learning in that ſeminary. He roſe ſucceſſively to various high ſtations in the church; and in 1360, king John appointed him preceptor to his ſon Charles, who became the fifth king of France of that name. In 1363, he was ſent to tranſact affairs of importance with pope Urban V., and the college of cardinals at Avignon, and on this occaſion he ſignalized himſelf by a diſcourſe which he delivered before the pope and cardinals, in which he inveighed bitterly againſt the ſcandalous irregularities of the papal court. This diſcourſe was publiſhed by Geſner at Wittemberg in 1604. Oreſme next excited much attention by another "Diſcourſe concerning the Changes in the Value of Money," in which he cenſured the conduct of thoſe princes who coined money below the juſt ſtandard, and maintained that they had no power to increaſe or depreciate the value of money at their arbitrary pleaſure. This diſcourſe is inſerted in the twenty-ſixth volume of the Bibl. Patr. Upon the acceſſion of Charles V. to the throne he loaded his former tutor with favours, and conſulted him on the moſt important affairs of government. In 1377, he nominated him to the biſhopric of Liſieux, over which he preſided till his death, in the year 1382. His acquaintance with divinity, philoſophy, the mathematics, and the belles lettres, was very extenſive, and profound for the age in which he lived. De Launoy, Dupin, Huet, and others contend that he tranſlated the Bible into French by order of Charles V.; but others, among whom is father Simon, in his "Critical Hiſtory of the Verſions of the New Teſtament," maintain that it was the work of Des Moulins, canon of Aire, who lived a hundred years before Oreſme, and ſome ſay it was done by Raoul des Preſles, an eminent contemporary of our author. It is not in our power to give any deciſion on this ſubject. Oreſme tranſlated into French Ariſtotle's "Morals and Politics," by order of Charles V.: he was likewiſe the tranſlator of ſome parts of Cicero's works; and the treatiſe of Petrarch, "De Remediis Utriuſque Fortunæ." He was author of many original pieces, among which were three treatiſes againſt judicial aſtrology. Moreri.

OREXIS, APPETITE. The appetite, when exceſſive, or otherwiſe vitiated, is diſtinguiſhed by medical writers into ſeveral kinds, and deſcribed under ſeveral names, according to its difference in degree, and other particulars.

The firſt kind is the *Addephagia:* this is the name given to that ſpecies in which the food is not only eaten in too large a quantity, but is ſwallowed in a particularly ravenous manner.

The ſecond is the *Orexis Canina:* in this caſe the patient is continually eagerly longing for food; and if it is not ready ſo ſoon as he deſires, he is ſubject to fainting-fits; after the recovery from which he does not feel the ſame craving appetite. See BULIMY.

The third is the *Pica*, or *Sitta:* this is the caſe when the patient has an eager appetite to things not fit for food; ſuch as chalk, cinders, tobacco-pipes, and the like.

The fourth is the *Malacia:* this is diſtinctively made the name of that ſpecies of exceſſive appetite in which the patient has a great deſire for ſome particular things, but thoſe of the nature of common food, and uſually of the nicer and more delicate kind. See APPETITE.

OREYPOUR, in *Geography*, a town of Hindooſtan, in Marawar; 25 miles N. of Ramanadporum.

OREZA, a town of the iſland of Corſica, in the department of Corte. The canton contains 4345 inhabitants.

ORFANEL, HYACINTH, in *Biography*, a Spaniſh Dominican monk, who became a martyr to his zeal for propagating the Catholic faith in Japan, was born in the kingdom of Valencia in the year 1578. He entered, when very young, into the order of St. Dominic; and in the year 1605, was ſent out a miſſionary to the Philippine iſlands. From thence he went to Japan, where he chiefly applied himſelf to the inſtruction of the poor, among whom he made many converts to the Catholic religion. While thus engaged, in what he conſidered a good cauſe, he endured great privations and ſufferings, and was at length arreſted, brought to a mock trial, and condemned to be burnt alive. This was in the year 1622. He contributed very much to the collection of miſſionary travels among the Pagans of the Eaſt, a work that was written in the Spaniſh language, which relates to a country little known to Europeans, and is ſaid to abound in curious and intereſting matter. So careful was the author to render his work perfectly accurate, that while he

was

was in priſon; he read it to his fellow miſſionaries, who aſſiſted him in correcting any miſtakes into which he might have fallen. It was printed at Madrid in 1633, and is entitled "The Eccleſiaſtical Hiſtory of the Succeſs of Chriſtianity in Japan from the Year 1602 to 1621, and continued to the End of the Year 1622 by father Diego Collado." Moreri.

ORFAR, a town of Scotland, on the S. coaſt of the iſland of Pomona; ten miles S.W. of Kirkwall.

ORFFYREUS's WHEEL, in *Mechanics*, is a machine ſo called from its inventor, which he imagined to be a perpetual motion. This machine, according to the account given of it by M. s'Graveſande, in his "Œuvres Philoſophiques," publiſhed by Allamand, Amſt. 1774, conſiſted of a large circular wheel, or rather drum, twelve feet in diameter, and fourteen inches in depth, and very light; as it was formed of an aſſemblage of deals, the intervals between which were covered with waxed cloth, in order to conceal the interior parts of it. The two extremities of an iron axis, on which it turned, reſted on two ſupports. On giving the wheel a ſlight impulſe in either direction, its motion was gradually accelerated; ſo that after two or three revolutions it acquired ſo great a velocity as to make twenty-five or twenty-ſix turns in a minute. This rapid motion it actually preſerved during the ſpace of two months, in the chamber of the landgrave of Heſſe, the door of which was kept locked, and ſealed with the landgrave's own ſeal. At the end of that time it was ſtopped, to prevent the wear of the materials. The profeſſor, who had been an eye-witneſs to theſe circumſtances, examined all the external parts of it, and was convinced that there could not be any communication between it and any neighbouring room. Orffyreus, however, was ſo incenſed, that he broke the machine in pieces, and wrote on the wall, that it was the impertinent curioſity of profeſſor s'Graveſande which made him take this ſtep. The prince of Heſſe, who had ſeen the interior parts of this wheel, being aſked by s'Graveſande, whether, after it had been in motion ſome time, there had been any change obſervable in it, or whether it contained any pieces that indicated fraud or deception, anſwered both queſtions in the negative, and declared that the machine was of a very ſimple conſtruction.

ORFO, in *Geography*, a town of Africa, in the diſtrict of Labadde, on the Gold Coaſt.

ORFORD, or OREFORD, a borough and market town in the hundred of Plomeſgate, and county of Suffolk, England, is ſituated on the north-weſt bank of the river Ore, from which it certainly derived its name. It was formerly a place of much greater conſequence than at preſent, and previous to the year 1500, contained three churches; but of theſe only one remains. In 1359 this town ſent three ſhips and ſixty-two men to aſſiſt Edward III. in the ſiege of Calais. Here, according to the "Suffolk Traveller," was a houſe of Auguſtine friars, an hoſpital of St. Leonard, and a chantry, which was valued at the diſſolution at 6*l.* 13*s.* 11½*d.*; and there are ſeveral lanes within the borough, and in its immediate vicinity, ſtill called ſtreets, though almoſt entirely deſtitute of houſes. The decay of the town is attributed to the loſs of its harbour, as the ſea has retired from this part of the coaſt.

The corporation of Orford conſiſts of a mayor, recorder, town clerk, eighteen portmen, twelve capital burgeſſes, and two ſerjeants at mace. Two members are ſent hence to parliament, in which the town appears to have been firſt repreſented in the reign of Edward I. Neglecting, however, to exerciſe its elective franchiſe during a long ſeries of years, it loſt this privilege, but it was reſtored by Richard III., who granted to Orford a charter of incorporation, and conferred on it many important immunities. Its market is on Monday, weekly, and there is a fair on the 24th of June: that formerly held on Shrove Monday is diſcontinued. This town gave the title of earl to admiral Ruſſell, who was elevated to the peerage by William III. Becoming extinct in that family, the ſame dignity was conferred on the celebrated ſir Robert Walpole, and continued in his family till the year 1797, when it again became extinct, by the demiſe of Horatio, the fourth earl, without iſſue. It has ſince, however, been once more revived, in the perſon of Horatio baron Walpole of Wolterton.

The church of Orford is of great antiquity, and was, when entire, a ſpacious and very handſome ſtructure. At the weſt end riſes a ſquare embattled tower, having under it the principal entrance, which is adorned on the outſide with ſhields, and a croſs over the centre, and in the interior with king's heads, five on one ſide, and ſix on the other. The chancel, now much more ruinous than any other part of the church, and ſeparated from it by a wall, exhibits in its remains a very curious ſpecimen of ancient architecture. In the more entire portions of this edifice the arches are in the pointed ſtyle, and the windows are ornamented with beautiful tracery, in good preſervation.

The other public buildings in Orford, beſides the church, are a town-hall and an aſſembly houſe.

On an eminence on the weſt ſide of the town ſtand the ruins of the caſtle, which was moſt likely founded ſoon after the Norman conqueſt, though neither the exact period, nor the name of the founder, are recorded. This fortreſs is traditionally ſaid to have been the centre of the town in ancient times; a report rendered extremely probable by the fact, that many foundations of buildings are frequently diſcovered in the ſurrounding encloſures, ſome of which likewiſe retain the name of ſtreets annexed to their denomination of field. The preſent remains of the caſtle conſiſt chiefly of the keep. The figure of this building is a polygon of eighteen ſides, deſcribed within a circle, whoſe radius is twenty-ſeven feet, and flanked by three ſquare towers, ſituated at equal diſtances on the weſt, north-eaſt, and ſouth-eaſt ſides. Theſe are embattled, and overlook the reſt of the edifice, which riſes to the height of ninety feet. The outer walls meaſure twenty feet in thickneſs, and are ſolid towards the baſe, but galleries and ſmall apartments are formed in them towards the upper part. Round the whole run two circular ditches, which were formerly ſeparated by a circular wall, now almoſt entirely demoliſhed. From the view of the caſtle, however, publiſhed by Groſe, we learn that this wall was forty feet high, and had a parapet and battlements. The entrance into the fortreſs was, on the ſouth-eaſt part of the polygon, through a building adjoining to one of the towers.

When mention of Orford caſtle firſt occurs in hiſtory, it belonged to the crown. In 1215, Hugh Bigod and John Fitz Robert were appointed governors both of Norwich and Orford caſtles; but were removed the ſame year, and Hubert de Burgh nominated in their ſtead. After the battle of Lewes, at which Henry III. was taken priſoner by his barons, they conferred the command of this poſt on Hugh le Deſpenſer. It next paſſed into the cuſtody of the deſcendants of Peter de Valoines, one of whom, Cecilia, daughter of Robert de Valoines, married Robert de Ufford, who had a grant of the caſtle and manor for life. William de Ufford died ſeiſed of it in the reign of Richard II., and Iſabel, his wife, had it aſſigned among other things for her dowry. Upon her death it reverted to Robert lord Willoughby, a deſcendant, by the female line, from Robert de Ufford, and continued

tinued in that family till the reign of Henry III. It deſcended afterwards to Michael Stanhope, and in his right to viſcount Hereford, whoſe truſtees ſold it to the father of the marquis of Hertford, the preſent owner.

Sudborne Hall, a ſeat of the marquis, ſtands about a mile north-eaſt from the town. It is a plain building, and chiefly uſed as a ſporting reſidence, for which purpoſe it is excellently ſituated, the park and neighbourhood abounding with game. The Suffolk Traveller, by John Kirby, 2d edit. Lond. 1764. Beauties of England and Wales, vol. xiv.

ORFORD, a poſt-town of America, in Grafton county, New Hampſhire, on the E. bank of Connecticut river, about 15 miles N. of Hanover, and oppoſite to Fairlee in Vermont: incorporated in 1761, and containing 988 inhabitants Here are the ſoap-rock, which has the property of fuller's earth in cleaning cloth, alum ore, free-ſtone fit for building, and a grey ſtone, much uſed for mill-ſtones, and reckoned equal in quality to the imported burr-ſtones.—Alſo, a townſhip in Lower Canada, W. of Aſcot, having about 30 inhabitants. In the northern part is a conſiderable lake, and another in the ſouthern part of the townſhip.

ORFORD, *Cape*, the north-weſternmoſt of the large iſlands to the W. of Falkland's ſound in the Falkland iſlands, in the Atlantic ocean, and S.E. of Cape Percival.

ORFORD, *Townſhip of*, lies in Suffolk county, Upper Canada: to the N. and S. is the reſidence of the Moravians: on the S. it is bounded by lake Erie, and towards the N. watered by the Thames.

ORFORDNESS, a cape of England, on the S.E. coaſt of the county of Suffolk, in the German ſea, where a light-houſe is erected for the direction of ſhips. N. lat. 52° 4′. E. long. 1° 6′.—Alſo, a cape on the E. coaſt of New Holland. N. lat. 11° 15′. W. long. 218° 9′.

ORFUS, in *Ichthyology*, a ſpecies of *Cyprinus*; which ſee.

ORGABRA, in *Geography*, a town of Africa, in the kingdom of Magadoxa.

ORGAL, or ARGOL, the lees of wine dried, and uſed by dyers to prepare the cloth for the more readily taking their ſeveral colours. See TARTAR.

ORGAN, Οργανον, is uſed in the general for any thing framed and deſtined for ſome certain action, uſe, or operation.

ORGAN, or *Organical Part*, in *Phyſiology*, is ſuch a part of the body as is capable of the performance of ſome perfect act, or operation.

In which ſenſe all the parts, even the moſt ſimple, may be denominated *organical*.

The organs are divided into *primary* and *ſecondary*. The *primary* are thoſe compoſed of ſimilar parts, and appointed for ſome one ſingle function. Such as conſiſt of ſeveral of theſe, though appropriated to one ſingle action, are eſteemed *ſecondary* organs.

Thus the veins, arteries, nerves, and muſcles, are *primary* organs; and the hands, fingers, &c. are *ſecondary* organs.

ORGAN *of Senſe*, is that part of an animal body, by means of which it perceives external objects.

Theſe, ſome divide into *internal*, which is the brain; and *external*, *viz.* the eye, ear, noſe, &c.

ORGAN, in *Fortification*. See ORGUES.

ORGAN, in *Muſic*, the name of the largeſt, moſt comprehenſive, and harmonious of muſical inſtruments; on which account it is called "the organ," οργανον, "the inſtrument" by way of excellence. The invention of the organ is very ancient, though it is agreed, it was little uſed till the eighth century. It ſeems to have been borrowed from the Greeks. Vitruvius deſcribes one in his tenth book. The emperor Julian has an epigram in its praiſe. St. Jerom mentions one with twelve pair of bellows, which might be heard a thouſand paces, or a mile; and another at Jeruſalem, which might be heard to the mount of Olives.

Ancient annaliſts, ſays Dr. Burney, are unanimous in allowing, that the firſt organ which was ſeen in France was ſent from Conſtantinople, as a preſent from the emperor Conſtantine Copronymus VI. in 757, to king Pepin; which, as well as Julian's epigram, gives the invention to Greece, where the hydraulicon had likewiſe its origin.

It has been a ſubject of debate, when the uſe of organs was introduced into the church. Bellarmine ſays, that they began to be uſed in the ſervice of the church, in the time of pope Vitalian, about the year 660, as Platina relates out of the Pontifical; or, as Aimonius thinks, after the year 820, in the time of Lewis the Pious. A learned writer has ſhewn, that neither of theſe dates can be juſt; alleging that Thomas Aquinas expreſsly ſays, that in his time, *i. e.* about the year 1250, the church did not uſe muſical inſtruments, leſt ſhe ſhould ſeem to judaize. Pierce's Vind. of the Diſſenters, ed. 1718, p. 395.

Bingham, in his Antiq. of the Chriſtian Church, vol. i. p. 314. folio ed. adds, that Marinus Sanutus, who lived about the year 1290, firſt brought the uſe of them into churches. However, it appears from the teſtimony of Gervas, the monk of Canterbury, who flouriſhed about the year 1200, that organs were introduced more than one hundred years before this time: in his deſcription of Lanfranc's church, as it was before the fire in 1174, he has theſe words, "Crux auſtralis ſupra fornicem organa geſtare ſolebat." Decem Scriptores, p. 1293, line 25.

Venerable Bede, who died in 735, ſays nothing of the uſe of organs, or other inſtruments, in our churches or convents, when he is very minutely deſcribing the manner in which the pſalms and hymns were ſung. However, according to Mabillon and Muratori organs became common in Italy and Germany during the tenth century, as well as in England; about which time they had admiſſion in the convents throughout Europe. Burney's Hiſt. Muſic, vol. ii. p. 66. 114.

Our elegant poet, the late Mr. Maſon, a good muſician, intereſted himſelf much in enquiries concerning the progreſs of the art, in his "Eſſays on Engliſh Church Muſic." He there gives ſeveral hiſtorical notices concerning the origin and progreſs of the organ, previous to its general admiſſion into our churches, partly extracted from a very voluminous work, entitled "L'Art da Facteur des Orgues, par D. Bedos de celles," a Benedictine monk, printed in 1766. We have not room to extract from Mr. Maſon's little work, and can only refer to it.

The complicated nature of the mechaniſm of an organ, renders it a very difficult taſk to give a clear deſcription of it. To make it more intelligible, we ſhall ſeparately deſcribe the ſeveral parts; and then, by referring the reader to a plate of the interior of a church organ, ſhew the diſpoſitions and uſes of them when put together.

The modern organ conſiſts of ſeveral parts; *viz.* the bellows, the porte vent, or wind trunk, the wind cheſt and its furniture, the ſound boards, the ſliders, the ſtock and rack boards, the pipes, the key and draw-ſtop movements.

The bellows are of two kinds, ſingle and double; the former are commonly uſed in church organs, the latter in chamber organs. Single bellows conſiſt of two oblong boards, *a b*, *c d*, (*Plate* I. *Organ*, *fig.* 10.), connected at *b* by a joint of leather

leather or web, and at the other three ſides by thin folds of wood joined together with leather. The lower board is fixed, the upper moveable. In the lower board, at *e f*, is an aperture covered with a valve, (called by the organ builders a pallet,) opening inwards. At *g* is another aperture, covered with a hollow box *g d*, communicating with the wind trunk; upon the mouth of which, is another pallet opening outwards. When the upper board, *a b*, is raiſed by preſſing down the handle of the lever *h i*, the air enters the bellows at the aperture *e f*, and upon letting go the lever, is forced into the wind trunk at *d*, by the preſſure of weights placed upon the upper board. The pallet at *d* prevents the return of the wind from the wind trunk, when the upper board is raiſed. It will eaſily be ſeen, that it is neceſſary to have at leaſt two pairs of bellows of this kind, to keep up a conſtant ſupply of wind. Moſt of the Engliſh church organs have three; and many of the large German inſtruments (as Dr. Burney informs us) have twelve and even ſixteen pairs.

Double bellows are made with three boards; *a b*, (*fig.* 11.) the riſer; *c d*, the middle; and *e*, *f*, the feeder boards. At *g*, in the feeder, is an aperture, and pallet to receive the air; at *h*, in the middle board, is the pallet of communication; and at *i*, in the riſer, the waſte pallet, which is contrived to open, when the bellows are ſufficiently full. The riſer empties itſelf into the wind trunk at *c*. In old bellows of this kind, the riſer is connected with the middle board, in a manner ſimilar to the ſingle bellows; but it is now uſual to join them with folds of an equal breadth in all parts, ſo that the upper board, in riſing, is always parallel to the middle board. Theſe are called horizontal bellows; in contradiſtinction to thoſe which riſe diagonally. Their action is very ſuperior to thoſe of the old form. They afford a greater quantity of wind, in proportion to the caſe room they occupy; the preſſure is more equal; and they are not liable to jerk or quiver. Though lately brought into common uſe, they are by no means a modern invention, as Père Merſenne deſcribes them under the name of bellows "à la lanterné." L'Harmonie Univerſelle, folio, Paris, 1636.

The ſound board (*fig.* 12.) is made of an oblong frame, the upper ſide of which is covered by a ſtout board. In the two longeſt ſides of the frame, and in the under ſide of the board, grooves are dug, in which are fixed a number of bars of wood; dividing the box thus formed into parallel channels, completely ſeparated from each other. A number of holes, correſponding with the number of ranks of pipes of which the organ conſiſts, are bored through the upper ſide of the ſound board into each channel. The number of channels is regulated by the compaſs of the organ; there being uſually a channel to each finger-key.

The wind cheſt is attached to the under ſide of the ſound board. It is a box made air-tight in all parts, ſo that the wind, which it receives from the bellows through the wind trunks, cannot eſcape, except through the channels of the ſound board. Each of the channels within the wind cheſt is covered with a pallet, which opens downwards, and is cloſed by the action of a ſpring of braſs wire. The pallet is connected with the key movement by ſmall wire hooks, which paſs through a perforation in a braſs plate, upon the bottom of the wind cheſt. *Plate* I. *fig.* 2. ſhews a pallet with its ſpring, cheſt hook, and pull-down. All the under ſide of the ſound board, which is without the wind cheſt, is cloſely covered with leather, or parchment.

Upon the upper ſide of the ſound board are placed thin bars of wood, called the ſliders; extending the whole length of the ſound board, and pierced with holes, correſponding with thoſe bored through the ſound board, into the channels. Theſe ſliders, being moveable in grooves in a tranſverſe direction to the channels, admit, or exclude, the wind from any rank of pipes placed over them, as the holes correſpond with, or cover, thoſe of the ſound board. Laſtly, upon theſe are ſcrewed the ſtock boards; which are alſo bored with holes correſponding with thoſe in the ſliders and ſound board; in which the pipes are placed. The racks are thin boards mounted on ſmall pillars, pierced to receive the upper part of the feet of the pipes.

The key movement is a combination of rollers and levers, or of quadrants connected by wooden rods; ſo contrived, that each key, when preſſed down, may open its correſponding pallet in the wind cheſt, and ſo admit the wind to the pipes, ſtanding over the channel, which the pallet covers.

The draw-ſtop movement is alſo a combination of levers and rollers, ſo contrived, that each draw-ſtop may open or ſhut its correſponding ſlide; and ſo admit or exclude the wind from that rank of pipes to which it belongs. Thoſe ranks of pipes, which in the conſtruction of the inſtrument are ſo planted as to be ſubſervient to the action of one draw-ſtop, are called ſtops. A ſtop conſiſting of one row of pipes is called ſimple, of more than one compound.

The pipes are of four kinds, ſtopped, half ſtopped, (with a funnel or chimney at the top,) open and reed pipes. Various materials have been uſed for their conſtruction, but the moſt common practice is to make the ſtopped pipes of wood, and the open and reed pipes of a metal compoſed of tin and lead.

Plate I. *figs.* 1. and 2. repreſent the front and ſection of a ſtopped wooden pipe. In *fig.* 2. *a* is a ſquare block of wood, correſponding with the interior diameters of the pipe, upon which the back and two ſides are glued. In this a channel is cut, in the direction of the ſhaded line, for the paſſage of the wind, which entering at the foot *d*, paſſes through the channel in the block, and the cavity of the lip or top piece *b*, and ſtrikes upon the ſharp edge of the front at *e*, the mouth; *c* is a moveable wooden tompion, covered with leather to make it air-tight. When this is drawn outwards, the tone of the pipe is flattened, and when puſhed inwards, ſharpened.

Figs. 3. and 4. repreſent the front and ſection of an open metal pipe. *Fig.* 4. *d* is the foot, which is a hollow cone, and is ſeparated from the cylindrical body of the pipe *c*, by a partition called the langue, or tongue, *a*, which anſwers the purpoſe of the block in the wooden pipe. The wind paſſes through a narrow aperture at *b*, and ſtrikes upon the upper ſide of the mouth at *e*. A ſmall ear is uſually affixed on each ſide of the mouth, for the purpoſes of enriching the tone, and to tune ſuch pipes as ſtand in the ornamental front of the organ. Metal open pipes are tuned by opening the tops with a braſs cone, to ſharpen them; and by cloſing them with the inſide of the cone, to flatten them.

Figs. 5. and 6. are the front and ſection of an half ſtopped pipe, or pipe "à la cheminée." Theſe pipes are tuned by opening or cloſing the ears, which are made very large for this purpoſe.

Fig. 7. is the exterior of a reed pipe, conſiſting of two parts, the foot, *a*, and the tube or body of the pipe, *b*. The tube is ſoldered to a block of metal, *c*, (*figs.* 8. and 9.) which exactly fits into the upper end of the foot. In this is fixed a hollow demi-cylinder, *d*, of braſs, called the reed,

reed, ſtopped at the lower extremity, and communicating at the other with the body of the pipe. The open ſide of the reed, (the edges of which are filed perfectly flat and paralle,) is covered with a thin plate of hard braſs. called the tongue; one end of which is kept in its poſition by a ſmall wooden wed e *f*, and the other left at liberty to vibrate with the action of the wind. The degree of acuteneſs, or gravity of a reed pipe, depends jointly on the length of the tongue, and that of the pipe; meaſured from the extremity of the reed to the extremity of the tube. It is, therefore, neceſſary to have ſome method of altering the length of the reed, in order to tune the pipe. This is effected by pulling up, or puſhing down, the wire-ſpring *g*; which preſſing the tongue cloſely againſt the reed, ſhortens or lengthens the vibrating portion of it. The degree of gravity, or acuteneſs of any pipe, depends upon the length; meaſured in an open pipe, from the edge of the mouth to the extremity of the tube; and in a ſtopped pipe, from the edge of the mouth to the interior ſurface of the tompion. A ſtopped pipe is half the length of an open pipe of the ſame pitch.

The following liſt contains the names of the ſtops which are commonly uſed by Engliſh builders.

Stopped Pipes.—The bourdon, or double-ſtopped diapaſon, the ſtopped diapaſon, and ſtopped flute.

Open Pipes.—The preſtant, or double open diapaſon, the open diapaſon, dulciana, principal, open flute, twelfth, fifteenth, tierce or ſeventeenth, larigot or nineteenth, and twenty-ſecond.

Reed Pipes.—The trumpet, clarion, baſſoon, hautboy, French horn, cremona, and vox humana.

Compound ſtops, uſually conſiſting of open pipes, are the cornet, ſeſquialtera, furniture, mixture and ſupplement.

The organ has from one ſet of keys, in chamber organs, to four or five ſets, in the largeſt church organs. Each of theſe ſets of keys acts upon a ſeparate organ, which has nothing in common with the others, except the caſe and bellows.

The number of keys, or compaſs of the organ in the time of father Schmidt, was commonly confined to four octaves; from double C in the baſs, to *c* in alt. To theſe, two notes, G G and A A, were ſometimes added to the loweſt octave. An organ of this compaſs is ſaid to have ſhort octaves. When the keys are extended to G G in regular ſucceſſion, the organ is ſaid to have long compaſs. The modern builders have extended the keys upwards to *f* in alt^mo.

Beſides the manuals or keys for the hand, there are, in large church organs, pedals, or keys played with the feet; ſaid to be the invention of Bernard, a German, about the year 1400. Theſe command certain pipes, which, to increaſe the harmony, are tuned an octave below the diapaſon. It is much to be lamented, that the Engliſh builders have not followed ſome certain and invariable rule for the poſition of their pedals, as they do for their keys. Scarcely two organs in the kingdom have their pedals alike; either with reſpect to number or poſition; ſo that every performer who comes to an organ, with which he is not previouſly acquainted (be he ever ſo ſkilful in the uſe of pedals), has the whole of his buſineſs to learn again. The diſpoſition of the pedals of the fine organ in St. Paul's cathedral, might ſerve as a model for all other Engliſh organs. Each octave of the pedals occupies the ſpace of two octaves of the finger-keys; and the C's are placed under each other, as repreſented in *Plate* I. *fig.* 13.

Plate II. repreſents the interior of an Engliſh church organ, ſeen in profile. It has three rows of keys. The upper row is appropriated to the ſwell, the middle to the great or chorus organ, and the lower to the choir or ſoft organ. The ſwell is ſaid to be an Engliſh invention, and Dr. Burney, in his Tour through Germany, ſays that he found only one organ in which a ſwell had been attempted, and that in a very imperfect manner. The ſwell has its pipes incloſed in a ſtout wooden box, with a ſliding door; which being gradually opened by the preſſure of the performer's foot, the ſound is increaſed, and is diminiſhed by a contrary motion. The ſwelling organ is commonly placed in the upper part of the caſe, either over the great organ, or over the choir, as repreſented in the plate.

The great organ is commonly placed in the fore part of the caſe, for the convenience of planting the largeſt pipes in the ornamental front; and that it may appear louder.

The choir organ is ſometimes placed in the poſition drawn in the plate; and ſometimes in front of the great organ, in a ſeparate caſe, at the back of the player. Hence it is not unfrequently called the chair organ.

The key movement of the choir organ, as repreſented in the plate, is of that kind called the *long* movement; becauſe it may be extended to an almoſt indefinite length. It was uſed for the organ at the commemoration of Handel in Weſtminſter Abbey; when the keys were 23 feet from the organ; and 19 feet below the level of the common key frames. The conſtruction muſt be obvious to any one who has obſerved the common method of hanging bells. The trackers in the organ are of wood, inſtead of wire.

The organ at Haarlem, the moſt celebrated inſtrument in Europe, has been already deſcribed, from an actual ſurvey. (See HAERLEM.) But the liſt of the ſtops we reſerved for the general article organ.

Catalogue of the Stops in the great Organ at Haarlem, built by Müller, 1738.

Great Manual.

No. Names.	Length of longeſt Pipe.	Engliſh Equivalents.
1. *Preſtant,*	16 feet.	Open double diapaſon.
2. *Bourdon,*	16	Stopt ditto.
3. *Octave,*	8	Open diap.
4. *Viol da Gamba,*	8 A narrow pipe which imitates the whiſtling of the bow.	Uniſon with ditto.
5. *Roer Fluit,*	8 With a funnel, or ſmall pipe, upon the top.	Diap. half ſtopt.
6. *Octave,*	4	Principal.
7. *Gem's Hoorn,*	4 A kind of flute, the pipes narrow at the top.	Uniſon with ditto.
8. *Roer-Quint,*	6	Twelfth half ſtopt.
9. *Quint,*	3	Fifth.
10. *Tertian,*	2 ranks.	Tierce or 17th.
11. *Mixture,*	6, 8, and 10 ranks.	Furniture, or mixture.
12. *Wood Fluit,*	2 feet. Stopt pipe, uniſon with the	Fifteenth, or octave flute.
13. *Trumpet,*	16	Double trumpet.
14. *Trumpet,*	8	Trumpet.
15. *Trumpet,*	4	Clarion.
16. *Hautbois,*	8	Hautbois.

Reed ſtops.

Upper Manual.

No.	Names.	Length.	Engliſh Names.
1.	*Preſtant,*	8 feet.	Open diapaſon.
2.	*Quintadeena,*	16 Breaks into a 5th, which predominates.	Double diap.
3.	*Gem's-Hoorn,*	8	Unif. with ſtopt diap.
4.	*Baar pyp.*	A muffled pipe uſed with the *vox humana.*	Bear pipe.
5.	*Octave,*	4	Principal.
6.	*Flag Fluit,*	4 Reed-flute.	Flute.
7.	*Naſſat,*	3	Stopt twelfth.
8.	*Nagt-Hoorn,*	2 *Night-horn;* but why ſo called, no reaſon can be given.	Flute.
9.	*Flageolet,*	1½	Octave twelfth.
10.	*Seſquialter,*	2 ranks Tuned octave and 12th to the diap.	Seſquialter.
11.	*Cimbaal,*	3 ranks.	Octave to mixture.
12.	*Mixture,* 4 and 6 ranks.	A ſeries of eight notes repeated thro' the inſtrument.	Mixture.
13.	*Schalmay,*	8 Reed ſtop.	Bagpipe.
14.	*Dulcian,*	8 A narrow delicate pipe, uniſon with the diap.	Dulcian.
15.	*Vox humana,*	8 An imitation of the	human voice.

Poſitif, or ſmall Organ.

Loweſt Set of Keys.

No.	Names.	Length.	Engliſh Names.
1.	*Preſtant,*	8 feet.	Open diapaſon.
2.	*Holfluit,*	8	Diap. half ſtopt.
3.	*Quintadeena,*	8	Ditto.
4.	*Octave,*	4	Principal.
5.	*Flute,*	4	Flute.
6.	*Speel Fluit,*	3	Twelfth.
7.	*Seſquialter,*	2, 3, and 4 ranks.	
8.	*Super-Octave,*	2 feet.	Fifteenth.
9.	*Scherp,*	6 and 8 ranks.	High mixture.
10.	*Cornet,*	4 ranks.	
11.	*Cimbaal,*	3 ranks.	Octave mixture.
12.	*Fagotte,*	16 feet.	Double baſſoon.
13.	*Trumpet,*	8	
14.	*Regaal,*	8 Formerly a portable organ uſed in proceſſions, was called a *regal;* the ſtop in this organ is entirely compoſed of reeds.	Regal.

Pedals.

No.	Names.	Length.	Engliſh Names.
1.	*Principal,*	longeſt pipe 32 feet.	Octave below the double diapaſon.
2.	*Preſtant,*	16	Double diap. open.
3.	*Subbas,*	16	Ditto, ſtopt.
4.	*Roer Quint,*	12	Fourth below the diap. ſtopt.
5.	*Holfluit,*	8	Diap. half ſtopt.
6.	*Octave,*	8	Open diap.
7.	*Quint-Preſtant,*	6	Fifth.
8.	*Octave,*	4	Principal.
9.	*Ruſch-Quint,*	3 ruſh *or* reed	Twelfth.
10.	*Holfluit,*	2	Fifteenth.
11.	*Bazuin,*	32 By the Germans called *Poſaune,* a reed ſtop.	Double Sacbut.
12.	*Bazuin,*	16	Sacbut.
13.	*Trumpet,*	8	Trumpet.
14.	*Trumpet,*	4	Clarion.
15.	*Cink,*	2 A cornet, horn, or ſhawm,	Octave Clarion.

This organ has 60 ſtops, two tremulants, two couplings, or ſprings of communication, four ſeparations or valves to cloſe the wind cheſt of a whole ſet of keys, in caſe of a *cipher,* and 12 pair of bellows.

Upon the whole, it is a noble inſtrument, though we think that of the New church at Hamburg is larger, and that of the Old Kerk, in Amſterdam, better toned; but all theſe enormous machines ſeem loaded with uſeleſs ſtops, or ſuch as only contribute to augment noiſe, and to ſtiffen the touch.

As this organ contains many ſtops, which are altogether unknown to Engliſh builders, and not to be found in the organs of this kingdom, we have ſubjoined a liſt of the ſtops of the organ at Great Yarmouth, as this noble inſtrument contains nearly all the variety of ſtops with which our workmen are acquainted.

The organ was built by Jordan, Bridge, and Byfield, in the year 1740, though roughly repaired, and ſome ſtops added, by Mr. G. P. England, in 1812.

Compaſs of the great and choir organs from G G, to *f* in altiſſimo; of the ſwell from C below middle, to *f* in altiſſimo. Pedals from G G G, to C C.

Thoſe who wiſh to be further informed in the hiſtory and practice of organ building, are referred to L'Harmonie Univerſelle, folio, Paris, 1636; Harmonicorum Libri Duodecimi, folio, Paris, 1648; Facteur d'Orgues, Paris, 1766; and Mr. Maſon's Eſſays on Engliſh Church Muſic.

The organs in our churches, that have been well preſerved of father Schmidt's make, ſuch as St. Paul's, the Temple,

St. Mary's, Oxford, Trinity college, Cambridge, &c. are far ſuperior in tone to any of more modern conſtruction; but the mechaniſm has been improved during the laſt century, by Byfield, Snetzler, Green, Gray, &c. The touch is lighter, the compaſs extended, and the reed-work admirable. The dulciana ſtop, brought hither by Snetzler, is a tall, delicate, narrow pipe, of an exquiſite ſweet tone, without a reed; on which account it ſtands in tune equally well with the open diapaſon. Though the beſt keyed-inſtruments in England have been made by Germans, they work here better than in their own country in ſize and number of ſtops; they greatly ſurpaſs us in the ſize of their organs, but the mechaniſm is infinitely inferior; which is accounted for by the workmanſhip being better paid here than in the German dominions, where labour is cheap.

The long keys of our old church organs were made of box or ebony, and the ſhort, or flats and ſharps, of ivory. But at preſent, the long keys, or natural notes, like thoſe in harpſichords and piano-fortes, are of ivory, and the flats and ſharps of ebony, or dyed pear-tree wood.

An organ, when complete for cathedrals, is of three-fold conſtruction, and furniſhed with three ſets of keys; one for what is called the great organ, and which is the middle ſet, a ſecond (or lower ſet) for the choir organ, and a third (or upper ſet) for the ſwell. In the great organ, the principal ſtops are known by the following names; the two diapaſons, the principal, the twelfth, the fifteenth, the ſeſquialtera, the mixture or furniture, the trumpet, the clarion, and the cornet. The choir organ uſually contains the ſtop diapaſon, the dulciana, the principal, the flute, the baſſoon, and the vox humana. The ſwell compriſes the two diapaſons, the principal, the hautboy, trumpet, and cornet. Beſides this complete organ, there are other organs of ſmaller ſizes and more limited powers, adapted to church, chapel, and chamber uſe. There is alſo the barrel, or chamber organ, which has the parts of other organs, with the addition of a cylinder, or barrel, revolving on pivots: on the circumference of this, by means of wires, pins, and ſtaples, are ſet the tunes it is intended to perform. Theſe pins and ſtaples, by the revolution of the barrel, act upon the keys, and give admiſſion to the wind from the bellows to the pipes. The barrel organ is frequently made portable, and ſo contrived, that the ſame action of the hand which turns the barrel ſupplies the wind, by giving motion to the bellows.

Of all muſical inſtruments, the barrel organ is the moſt eaſy of performance, as it merely requires a regular motion given to it by a handle. On this account, it is an inſtrument of very general uſe; and the recent improvements of ſome Engliſh artiſts have rendered the barrel capable of producing an effect equal to the fingers of the firſt-rate performers. Barrels are now very generally added to chamber organs, operating on the ſame pipes as the finger-keys, though by a different ſet of keys; ſo that either barrel or finger-keys may be uſed independently of each other. Many barrel organs are conſtructed on an extremely ſmall ſcale, motion being given to them by clock-work. The whole inſtrument is frequently concealed in ſome piece of furniture, and the clock, being previouſly wound up, is put in motion at pleaſure, by diſcharging a trigger, producing a very agreeable effect to thoſe unacquainted with the concealment.

In order further to explain the mechaniſm of an organ, we have procured ſections of a moſt ſuperb inſtrument of this kind, made by Meſſrs. Flight and Robſon of London, for the earl of Kirkwall. As a finger organ, this inſtrument does not contain any thing new in principle; but the perfection of its workmanſhip is ſuch, as to produce effects which the organ would never have been thought capable of before this inſtrument was completed, and publicly exhibited to immenſe numbers of viſitors, at Mr. Flight's houſe in St. Martin's Lane. The mechaniſm of the barrel part is extremely ingenious, containing many new movements, which are neceſſary to give this method of performance the ſame powers as a good organiſt has upon the finger-keys; in this, however, the inventor has ſucceeded to his wiſhes. *Plate* III. *Organ, figs.* 1 and 2. are two ſections of the whole inſtrument, the firſt being taken acroſs the length, ſhewing one of the finger-keys, with the manner of its communication with the valves and pipes ſituated in the upper part, and alſo a croſs ſection of the barrel in its proper ſituation. *Fig.* 2. is a ſection taken on a plane perpendicular to the other, that is parallel to the front of the inſtrument, and through its centre; ſo that the barrel and all its appurtenances are removed, and only the detents, &c. of the finger-keys exhibited. We ſhall firſt deſcribe thoſe parts which are common to all organs, that the reader may better comprehend the variations and improvements of the preſent inſtrument. The bellows for ſupplying the air are placed beneath the inſtrument, near the floor at A B C in both figures; theſe throw a conſtant ſupply of air into the large chamber D, which ſerves as a regulator to receive it and equalize its preſſure, for which purpoſe it is termed the reſervoir: from this the air is conducted through the wind trunk E, to the wind cheſt F: from the top of this cheſt paſſages are conducted up to the various pipes ſituated at G, H, I, K, L, M. The paſſages are cloſed by valves within the cheſt at *k*, (*fig.* 1.) and a whole row of them may be ſeen in *fig.* 2: from theſe valves ſmall wires, *l*, deſcend, and by levers, N, communicate, by the rods Q, with the finger-keys O, P: the extremity, P, (*fig.* 1.) of one of theſe being preſſed down, elevates the front end of one of the levers N, and pulling the wire, *l*, at the other end, opens the valve *k*, and admitting air from the wind cheſt into the pipe above, it produces the ſound proper for that key.

Having given our readers a general idea of the diſpoſition of the parts, we ſhall proceed to a particular deſcription of the conſtruction of each. The bellows at A B C conſiſt of a moving board *a b*, (*fig.* 1.) having valves in it ſhutting downwards, to take in the air; it is connected by leather, glued all round its edges, with a large board *c c*, which as it extends beneath the whole inſtrument, and is united with its frame, may be called its floor or bottom. The floor has holes through it covered by valves, ſhutting downwards. The chamber formed by the ſpace between the floor and the moving board *a b*, is divided into two ſeparate compartments by a vertical partition above *d*, extending from one board to the other: the board, *a b*, is jointed by hinges and leather to this partition at the point *d*, and when worked, vibrates on this joint as a centre, enlarging one chamber and diminiſhing the other; which operation, by the arrangement of the valves, throws a conſtant ſtream of air into the reſervoir, D, of the bellows. Thus, ſuppoſe the end, *a*, of the board aſcending, and the other, *b*, deſcending, then the valves in *b* will be open to take a ſupply of air into their chamber. The valves in *a* will be ſhut, and the air included in that chamber is forced up through the valves, in the middle board *c*, into the reſervoir D, which is ſituated above it. Though we have only mentioned one pair of theſe double bellows, there are in reality three pair, all made exactly alike: they are denoted by the letters A, B, C, *fig.* 2. The middle bellows B, which are much wider than the other two, are intended to be worked by the foot of the performer, by means of a treadle, which comes out in front of the inſtrument, beneath the key-board, as denoted by the dotted lines *b*, *fig.* 1. The other two pair, A and C, are worked by the

ſame handle as the barrel: when it is uſed, this handle is applied to a ſpindle *w*, (*fig.* 1.) proceeding acroſs the whole inſtrument, and communicating motion to the barrel by means of wheelwork we ſhall deſcribe: on the other extremity of this ſpindle is a fly-wheel *x*, to regulate the movement, and a crank, which by a rod, *z*, communicates motion to one end of the bellows C, at the end *a*, *fig.* 1. There is alſo another crank at *z*, bent at right angles to the former: this crank communicates, by a horizontal rod, with a bent lever behind the inſtrument, which works the other pair of bellows at A, ſo that both pair, A, C, are in conſtant motion.

The reſervoir, D, is the ſize of the whole floor of the organ, and is common to all the three pair of bellows: it conſiſts of a large flat board, joined by folded leathers on all ſides to the floor board, forming a large chamber for the reception of the air from the different bellows. The weight of this board, always reſting upon the included air, cauſes a preſſure of air, and affords a regular and equable ſupply to the pipes during any momentary intermiſſion of the action of the bellows; nor can the preſſure on the air ever exceed what is produced by the weight of the upper board, for if more air is thrown into it than paſſes off to the pipes, the top board riſes; but when it gets to the height which is intended, a ſtring, faſtened to the top board, raiſes up a valve in the floor board, and ſuffers the air to eſcape, by returning into the bellows below. By this means the reſervoir can never be in danger of burſting. A ſtring is faſtened to the top board of the reſervoir, and paſſes over a ſmall pulley *y*, (*fig.* 1.) fixed on the end of a light ſpindle which comes through the front of the inſtrument over the keys, and has a hand or index at *y*, pointing to marks upon a ſmall dial plate, indicating the height to which the top has riſen, and, conſequently, the quantity of air in the reſervoir, ſo that this index ſerves as a guide to the performer, to blow as much as is neceſſary to keep the reſervoir full, but no more.

The wind cheſt, F, is now to be deſcribed: this is a ſhallow box, as the ſection ſhews, the whole ſize of the inſtrument, and ſuſpended in the frame: the air is conveyed from the bellows up to it by the wind trunk E E, at the end of the inſtrument: the wind cheſt contains a number of valves *k*, which at times permit the exit of the air; they are made of ſlips of leather with three pieces of wood glued to them, and are kept ſhut by a ſmall wire ſpring *w*, (*fig.* 1.) applied to each. The valves are opened by means of ſmall wires, *b*, coming down from them, through the bottom of the wind cheſt, and connected, as before mentioned, with the levers N. When any one is opened, the air paſſes out of the wind cheſt into a horizontal groove, which is ſeen juſt over the valves marked *i*, *k*, (*fig.* 1.) and aſcends through vertical paſſages into any of the pipes G, H, I, K, L, M, cauſing them to ſound: the wires, *b*, are hooked to the valves at their upper ends, and at the lower are jointed to the levers N: theſe have their centres fixed in the rail R, which extends along the whole inſtrument. At the oppoſite end of theſe, ſmall rods, Q, are jointed, which at the lower ends reſt upon the extreme ends, O, of the finger-keys O, P. By this arrangement, when the end, P, of any key is preſſed down, it raiſes the rod Q: this, by the lever N, draws down the wire *l*, thus opening the valve *k*, and by admitting air, cauſes the pipe or pipes belonging to that key to emit a ſound.

It has been before mentioned, that each key has ſeveral pipes of different tones, but tuned to the ſame note. In the inſtrument before us, there are ten pipes to each key, ſo that there are ten ſyſtems of pipes; but as only a part of theſe is ever required to be ſounded together, the ſtops or ſliders are provided to ſhut off or open the paſſages from each valve to as many pipes as the piece of muſic requires. The ſtops are ſituated at *e*, *f*, and *g*, in the boards placed over the wind cheſt; they are narrow rulers of mahogany (ſeen lengthwiſe in *fig.* 2.) ſliding in paſſages, which they exactly fill, and through which all the vertical paſſages to the pipes are conducted. The ſtops have holes through them anſwering to theſe paſſages, and when theſe holes are over the paſſages, they are open to allow the air to paſs through, but by drawing the ſlider endways a ſmall diſtance, the ſpaces between the holes in the ſtop apply themſelves over the paſſages, and ſhut them all up at once. Each ſtop or ſlider opens paſſages to a ſet of pipes, conſiſting of one pipe anſwering to each of the notes of the finger-keys: theſe pipes are gradually diminiſhed in length and ſize, from the largeſt baſs note to the ſmalleſt treble, as is ſhewn in the figures at G, H, I, K, L, M, in different rows, ſome of which contain only about half the number of pipes correſponding with the finger-keys, the remaining numbers being placed in other rows for want of room, and the upper board *e e*, called the ſound board, on which the pipes are placed, has horizontal paſſages cut in it, to conduct the air from each valve to its reſpective pipe, when the ſame is not ſituated exactly over it, as indeed very few are; for the number of pipes is ſo great, as to occupy all the ſpace on the ſound board, they muſt therefore be placed as the room will admit.

In the ſame manner, it will be obſerved in *fig.* 2, that the finger-keys O, O, are placed cloſe together in a ſmall ſpace, while the wires *l*, *l*, and the valves *k*, occupy the whole length of the inſtrument. To manage this, the levers, N, are not placed parallel, but diverging from each other, ſo that the ends, Q, are cloſe together, but the oppoſite ends are a conſiderable diſtance aſunder, and therefore come immediately beneath the valves: the wires are connected with theſe levers by nuts ſcrewed upon them, and this admits of adjuſting them, that the valves ſhall all be ſhut cloſe by their ſprings, when the finger-keys are all in a line, and at their higheſt poſition ready to be preſſed down.

It is ſeen in *fig.* 1, that each of the horizontal paſſages or grooves immediately above the valves *k*, have ten other paſſages riſing up from it, and in theſe, as before-mentioned, the ſtops are ſituated. There are three ſets of theſe ſtops, marked *e*, *f*, *g*, one above the other; but by drawing any of the three the ſame effect will be produced on the inſtrument, *viz.* ſhutting off or opening the row of pipes to which they belong. The three ſets of ſliders are for three different purpoſes; thus the loweſt ſet is moved by handles, or drawers coming out in front of the inſtrument, cloſe to the finger-keys, and they are drawn out to open the ſtops by hand; the middle ſet of ſliders is moved by the foot of the performer; the upper ſet is actuated by the barrel, when the organ is uſed in that manner. The organ pipes are of two kinds, of metal and of wood; the wooden ones are a ſquare trunk of deal wood A B, (*fig.* 3.) cloſed at one end by a moveable plug of wood D, and at the other by a piece of wood E, containing a crooked paſſage to bring air to the pipe, through the ſhort tube F; *a* is a piece of oak board glued to the block E, called the cap, and hollowed out, to communicate with the crooked paſſage, through the block, leaving a ſmall and very narrow crevice between the end of it and the edge of the block E, through which the air iſſues in one continued current; in its paſſage it is divided by the edge of one ſide, B, of the trunk, which is cut as ſharp as poſſible for that purpoſe, and which is exactly in the ſame line with the orifice whence the air is emitted. The ſound is produced by the vibration of the air which is contained in the trunk A B, and by increaſing or diminiſhing the length of this trunk the tone is

altered

altered at pleaſure, to bring it to the proper note it is to perform when placed in the inſtrument. This alteration of the length is made by ſliding the plug, D, up or down in the pipe.

A ſection of a metal pipe is ſhewn in *fig.* 4; it is nearly the ſame in operation as the wood pipe, though different in its conſtruction. It is a cylindric tube, A B, formed of a mixture of lead and tin, caſt in thin ſheets and ſoldered up; it is open at one end and nearly cloſed at the other by a partition, E, of the ſame metal, called the languid, which is circular for about two-thirds round, and ſoldered into the end of the pipe; the other third is a ſtraight edge, and made rather ſharp on the angle. F is a conical pipe conveying the air to the pipe: the upper end of this conical pipe is bent to be parallel to the edge of the languid E, and thus forms a ſmall cleft, ſimilar to the mouth of the wooden pipe for the paſſage of the air. The lower end, B, of the cylindrical pipe is bent into the line of the cleft, to divide the current of air. The metal pipes are open at top, and are brought to tune by enlarging or diminiſhing the pipe at the top, and thus altering its bulk; *a* is a piece of metal, called the ear, ſoldered upon the pipe at each end of the cleft, to prevent the ſtream of air being diſperſed ſideways, before it meets the edge or upper lip of the pipe. In the ſmall pipes this is not applied, and in the wood pipes its place is ſupplied by the edge of the wood board forming the ſide of the pipe, which is not cut away.

There is another kind of organ pipes, which have a reed in the mouth; they are called trumpet ſtops. One of theſe is repreſented in ſection at *fig.* 5. Here A is a cylindrical tube, bringing the air up from the wind cheſt, and on the top of it a leaden ring or ſocket, B, is fitted. This is the ſupport of the conical pipe, D, where the ſound is produced. The air paſſes into the tube D, through a braſs tube or reed *a*, which is ſtopped at the lower end, but has an opening down the front, where it is made flat. It is furniſhed with a tongue, or ſlender braſs ſpring *b*, which applies to this flat ſide and covers the opening. When the wind is impelled into the pipe A, it enters through the reed, and puts the tongue into a vibratory motion, which gives the peculiar tone of this pipe. The tongue is held in its place, againſt the reed, by a ſmall wedge thruſt in by the ſide of it, and a wire ſpring *d d*, which preſſes the tongue againſt the reed, determines the length of the tongue, which ſhall have liberty of free vibration; conſequently, by ſliding this wire up or down, the pipe is brought to tune.

The trumpet ſtop is the moſt powerful in the inſtrument, and improves the tone as much as it increaſes the peal of the chorus. Being tuned in uniſon with the diapaſons, it ſtrengthens the foundation, and ſubdues the diſſonances of the thirds and fifths of the ſeſquialtera, imparting to the compound a richneſs and grandeur of effect, adequate to the ſublimeſt ſubjects.

The names of the ſtops or ſyſtems of pipes uſed in this organ are as follows:

Twelfth, a metallic ſtop, ſo denominated from its being tuned twelve notes above the open diapaſon, which will be mentioned hereafter. This ſtop, on account of its pitch or tuning, can never properly be uſed alone. The open diapaſon, ſtop diapaſon, principal, and fifteenth, are the beſt qualified to accommodate it to the ear.

Stop diapaſon, a ſtop, the pipes of which are generally made of wood, and its baſe, up to middle C, always of wood. They are only half as long as thoſe of the open diapaſon, and are ſtopped at the upper end with wooden ſtoppers or plugs, which render the tone more ſoft and mellow than that of the open diapaſon. As the pipes of this ſtop are of large ſize, they cannot be contained in one row on the ſound board, they are therefore diſpoſed in two rows, and have two ſliders, one for the baſs the other for the treble.

Open diapaſon, a metallic ſtop, which commands the whole ſcale of the organ, and which is ſo called in contradiſtinction to the ſtop diapaſon, the pipes of which are cloſed at the top; this has alſo two ſliders for baſs and treble.

Principal, a metallic ſtop, originally diſtinguiſhed by that name, becauſe holding, in point of pitch, the middle ſtation between the diapaſon and fifteenth. It forms the ſtandard for turning the other ſtops. It has two ſliders.

Dulciana, a ſtop generally uſed in the choir organ. It poſſeſſes a peculiar ſweetneſs of tone, which it chiefly derives from the bodies of its pipes, being longer and ſmaller than thoſe of other ſtops. It is tuned in uniſon with the diapaſon, and equals them in compaſs upward.

Fifteenth, a ſtop which derives its name from its pitch or ſcale, being fifteen notes higher than that of the diapaſon. This ſtop and the twelfth, mellowed and embodied by the two diapaſons and principal, form a proper compound for accompanying choral parts in common choirs and parochial churches. It is divided into two rows on the ſound board for baſs and treble.

The ſliders which bring theſe different ſtops into action are moved by the following means: the lower ſet, Q, is drawn by levers at the ends of the inſtrument, which are formed on the upper ends of upright ſpindles *o*, *o*, (*fig.* 2.) turning on pivots ſupported by the frame: to the lower ends of theſe, long levers *p*, (*fig.* 2.) are fixed; and at the end of theſe, ſmall rods are jointed, which come through the front of the caſe of the inſtrument, cloſe to the finger-keys, and have ſmall ivory knobs fixed upon them. Theſe are marked with the names of the ſtops of pipes to which they belong, and any one being thruſt in moves its ſlider, and opens the ſtops of pipes, which will then be ſounded by preſſing the finger-keys. There are ten of theſe handles, *viz.* five on each ſide of the finger-keys, though only two on each ſide are ſhewn in the figure, to avoid confuſion: there being ten handles one is given to each of the ſliders in the lower ſet, as ſhewn in *fig.* 1, and their names and properties have before been mentioned. The middle ſet of ſliders, *f*, is drawn by bent levers, as ſhewn in *fig.* 2. at *r*: from the horizontal arm of this lever a wire proceeds to connect it with a pedal beneath the inſtrument, by which the ſlider is moved: theſe pedals are uſed in quick muſic, to change the pipes upon which the keys operate, by drawing another ſlider. There are only two of theſe pedals, but they operate upon all the ten ſliders: thus, the bent levers, *r*, are fixed upon horizontal axes, which carry ſeveral levers, to operate upon as many ſliders at once as are required. The pedals are for the left foot, one being longer than the other, ſo that the heel acts upon it, leaving the toes for the other: the firſt of theſe pedals ſhuts up the twelfth, both the fifteenths, and both the principals; the other pedal commands the remainder of the ſtops, except the dulciana. The finger-keys, O, P, are all together fitted in a kind of frame or box, which ſlides in a groove: in *fig.* 1. they are repreſented as drawn out to the full extent, but admit of being thruſt back out of the way to make no projection in front of the inſtrument. When drawn out as far as they will come, the end, *o*, of each key comes immediately beneath the end of each of the rods Q, which are retained in their poſitions by paſſing through holes in a fixed rail extended acroſs the keys. The parts of the organ being now ſo fully explained, it is needleſs to ſay much of their mode of action. The wind cheſt and reſervoirs are kept conſtantly full of air by the bellows, and

in

in this ſtate any key being preſſed down admits the air to the pipes. The ſtops which the performer expects to want are opened firſt; but by the pedals, as before mentioned, he can bring on or take off any others during the performance. There is alſo another pedal which actuates the ſwell; this is a number of valves or boards, fitted in the manner of Venetian blinds, and ſituated at 38, 38, (*fig.* 1.) forming the front of the cloſe caſe or cheſt which encloſes the pipes. Theſe valves, being gradually opened by the preſſure of the foot, give the power of increaſing the ſound, as the wind does the ſound of a peal of bells, or ſuppreſſing it in like manner, by cloſing them up. The ſwell is ſituated immediately behind the ornamental front of the inſtrument, which is in part only thin ſilk, ſtretched in a frame to admit the paſſage of the ſound. Each of the boards turns on pivots at its ends, and having ſhort levers, which are connected together by a rod 39, they all open or ſhut together. At the lower end of the rod is a ſpring to ſhut them cloſe, and they are opened by a lever 40 within-ſide, from which a wire deſcends to the treadle before-mentioned. The ſwell produced a moſt delightful effect in ſome muſic, giving the piano and forte to the organ, in a greater perfection than any other inſtrument admits of, not even excepting the violin.

The mechaniſm of the barrel comes now to be deſcribed, for we have hitherto ſpoken only of the finger-key. The ſection (*fig.* 1.) ſhews that there are two rows of valves in the wind cheſt. The uſe of the firſt ſet at *k* has been fully explained as belonging to the finger-keys; the ſecond ſet, marked *i*, are opened by the keys, *h*, of the barrel S; they admit the air from the wind cheſt into the ſame paſſages as the other valves, and therefore ſound the ſame pipes when opened: the valves are, like the others, cloſed by ſmall ſprings, and have wires, *m*, coming down through the bottom of the wind cheſt, and united to the ſhort keys *h*. Theſe and the other parts are more particularly explained by the enlarged view of the barrel at *figs.* 6, 7, and 8. of *Plate* IV., where it is ſhewn detached from the organ, with all its mechaniſm in perſpective; but as the parts would intercept each other, if placed in their proper ſituations, *figs.* 7 and 8 are repreſented as removed from the end of the barrel, though in reality theſe parts all come cloſe to the end of it. This is explained by *figs.* 10 and 11, the former being an end view of the barrel and all its parts, and *fig.* 11. an elevation in front ſhewing its whole length.

The keys, *h*, are in miniature, the ſame as the levers at N, (*fig.* 1.), but their oppoſite ends are operated upon by pins projecting from the circumference of the barrel S, having beaks, as the figures ſhew, upon which the pins operate in paſſing beneath them, to lift up the points of the keys: the pins in the barrel are ſo diſpoſed as to lift the keys in the ſame order and time, as any piece of muſic for which the barrel has been previouſly made. The keys all turn upon one wire as a centre of motion, which is ſupported by a wooden rail T, extended acroſs the inſtrument. To prevent the keys ſhifting ſideways, and by that means miſſing the pins in the barrel intended for them, they move in ſmall notches cut by a ſaw in a piece of braſs plate, which is ſcrewed to the front edge of the piece of wood T, and projecting beneath it: the wire, which forms the centre for the keys, is alſo fixed to the piece of wood T, which is called the key frame; it is ſupported at its ends on centre points, on which it riſes and falls as a centre of motion, to lift the points of the keys clear above the pins of the barrel. Theſe centre points are made in plates of braſs at *n*, ſcrewed to the ends of the frame, and projecting ſo as to bring the centre of motion to coincide with the joints at the ends of the keys *h*, with the wires, *m*, proceeding to the valves *i*, (*fig.* 1.) Theſe braſs plates carry projecting arms 1, which have ſcrews tapped through the extremities, and the points of theſe coming in contact with fixed ſtuds projecting from the frame, form reſts for the key frame; but by turning theſe ſcrews the diſtance of the points of the keys from the barrel can be regulated at pleaſure, that the keys may be properly lifted by the pins of the barrel.

The barrel is put in motion by a handle *w*, applied to the ſpindle *w*, (*fig.* 1.) before-mentioned, and ſhewn in *Pl.* II. at *fig.* 6: this has an endleſs ſcrew, 2, formed upon it, which acts in the teeth of a ſmall wheel, which is fixed on an axis, 3, parallel to the barrel, and proceeding towards its end, where it carries a broad pinion, 4, engaging the teeth of a large wheel, 5, fixed on the extremity of the barrel. By this means the ſame movement which, as before mentioned, blows the bellows, by the crank *x*, (*fig.* 1.) cauſes the barrel to revolve ſlowly. The manner in which the barrel is made to play a variety of different tunes in ſucceſſion is thus: the ſpaces between the keys *h*, as ſhewn in *figs.* 6 and 11. are ſufficiently wide to have eight rows of pins diſpoſed in them, therefore only one-eighth of the circles of pins are at once engaged with the keys, and by moving the barrel lengthways a ſmall quantity, an entire new ſyſtem of pins are preſented to the keys, and theſe are arranged to produce a different tune.

The barrel is ſupported on a frame of wood, which is repreſented detached in *fig.* 6; its poſition in *figs.* 1 and 2 is denoted by *s*; it ſlides in grooves, ſo as to be capable of being drawn out, for the purpoſe of changing the barrel, and putting in a different one, but when ſlid back to its proper poſition is retained by two bolts. The pivots of the barrel reſt in frames, 6, of braſs at each end, which are attached to the woodwork by centres, on which they move ſideways. A lever, 7, (*fig.* 6.) proceeds from each frame, and theſe are united by a wooden rail behind the barrel, which therefore cauſes the two frames to have the ſame movement on their centre, and carry the barrel forwards in the line of its axis, when at liberty. When in uſe it is confined by pieces of iron, 8, 9, moving horizontally on hinges fixed to the frame work, and preſſing on the ends of the pivots of the barrel. The piece 9 is preſſed by a ſpring behind it; the other piece, 8, at the oppoſite end of the barrel, is ſupported againſt the circumference of a wheel 10, (*fig.* 7.) which is formed like a ſnail, by continual variations of its radius. On the ſame ſpindle with this ſnail-wheel is another wheel, 11, divided on its edge with eight large notches, into which a roller at the extremity of a detent, 12, adapts itſelf: the detent being puſhed down by a ſtiff ſpring, always obliges the wheel, 11, to reſt in one of the eight poſitions correſponding to the eight notches for the roller, and every one of theſe poſitions produces a change in the ſituation of the barrel, becauſe of the different radii of the ſnail 10, which permits the piece of iron, 8, to move; the ſpring piece, 9, at the oppoſite end always keeping the end of the barrel pivot in cloſe contact with it: therefore, by turning the wheel, 11, round, the barrel is ſhifted a ſmall quantity every time a different notch of the wheel, 11, comes to reſt beneath the roller 12, and thus all its different tunes are played in ſucceſſion. The wheel, 11, is turned about by means of eight pins projecting from its ſurface, one anſwering to each notch; theſe are preſſed down by a catch 13, joined to a ſhort lever 14, projecting from an axis *q*, which alſo carries two other levers, marked 15 and 16: the former of theſe has at the upper end a wire, 15, coming through the frame of the organ, and furniſhed with a knob, by pulling which the lever, 14, is depreſſed, and the catch, 13, turning the wheel, 11, round one notch, ſhifts the tune of the barrel, as before explained. But without ſome contrivance to raiſe up the key-frame, T, when the barrel is ſhifted, its pins might catch ſome of the points of the keys, and break or

bend

bend them ſideways. To avoid this danger, the ſame lever, 15, which communicates motion to the wheel to ſhift the barrel, has a detent, 17, jointed to it at one end; it paſſes through the frame of the organ reſting upon a roller 18; the extremity of it is ſituated beneath a ſmall roller 19, which is attached to the front plate of the key-frame at its end: the operation of this is, that when the knob, 15, is drawn forwards to ſhift the barrel, the detent, 17, alſo advances, and an inclined or thicker part coming upon the roller 18, cauſes the end, 19, to riſe up, and lift the key frame T, (*fig.* 8.) ſo high, that the pins in the barrel will clear the keys before the barrel has began to move endways, by the ſhifting of the ſnail-wheel 10. The ſhift having been made, the knob, 15, is let go, and the return of the levers to their firſt poſition, by ſprings on purpoſe, permits the key-frame to deſcend, and all is ready for the next tune, which commences as ſoon as the barrel is turned round. To prevent the key-frame deſcending with a jerk, which might do it injury, a ſmall lever, 20, (*fig.* 8.) projects from it at one end, and has a wire proceeding upwards to a ſmall pair of bellows, 21, fixed up beneath the wind cheſt; they have no opening into them, except a hole through the top board, which is covered by a valve, ſhutting downwards, to permit the eſcape, but prevent the re-entrance of the air. The operation of this is, that when the key-frame is lifted up for the purpoſe of ſhifting the barrel, the bellows cloſe, and the air included in them paſſes out beneath the upper valve; but on the frame being ſuffered to deſcend, the air cannot ſpeedily obtain admiſſion into the bellows, as there is no other paſſage than from leakage, and this regulates its fall. Beſides theſe proviſions for ſhifting the barrel, the pinion, 4, (*fig.* 8.) is likewiſe detached from the wheel at the moment of its ſhifting, that it may have no impediment to its motion from friction. To explain this, we muſt obſerve that the pivot of the ſpindle, 3, is ſupported by a crooked lever, 22, (*fig.* 10.) moving on a fulcrum in the framing; the oppoſite end being preſſed down by a ſpring 23, fixed on the top of the frame *s*, always keeps the teeth of the pinion, 4, and wheel, 5, in cloſe contact with each other. The lever 1, attached to the key-frame, has a rod, 24, deſcending from it to connect with a ſecond lever, 25: this carries a rod, which is forked at the lower end, and embraces the pivot of the ſpindle 4. By this means, when the key-frame is lifted up, as before deſcribed, the lever, 1, is depreſſed, which, by the rod 25, forces down the end of the ſpindle 4, and diſengages the pinion from the barrel; but the moment the key-frame deſcends, the ſpring 23, at the end of the lever 22, preſſes up the wheels into gear with each other. That the ſhifting of the tune may be done by a pedal for the foot, as well as by pulling the knob 15, there is a rod deſcending from the end of the lever, 16, to the bottom of the inſtrument, where it is connected with a pedal; therefore, by depreſſing this, the ſame effect is produced as would be by drawing out the knob 15.

A great improvement in this organ is the circumſtance of the barrel being made to operate upon the ſtops, as well as the keys, by which means it performs any full piece of muſic with the fineſt effect. The mechaniſm by which the motion is given to the ſtops is very ingenious, and requires particular figures for its deſcription. The upper ſet of ſliders *e*, (*figs.* 1 and 2. *Pl.* I.) are appropriated ſolely for the barrel; they are moved at the left-hand end (*fig.* 2.) by being attached to vertical levers W; the lower ends of theſe are connected by light wooden rods, X, X, extending beneath the wind cheſt, to ſmall levers *t*, (*fig.* 1.); theſe are affixed to ſhort ſpindles, whoſe ſituation is marked by *v*, in *fig.* 1. Now it is evident, by that partially turning the ſpindle *v*, the lever, *t*, will draw the connecting rod X, and by the lever, W, actuate the ſlider, *e e*, of the ſtop. The figure alſo ſhews that the extremities of the ſpindles, *v*, are immediately over the extremities of the keys *h*. It is in the connection between theſe that the ingenious contrivance is ſhewn. *Fig.* 9 is a ſmall detent or three-armed lever, in ſhape of the letter T, called the tumbler, fixed on the projecting extremity of the ſpindle *v*; from each of its two arms, 26, 27, a pin projects: 28, (*figs.* 12 and 13.) is a detent of braſs, connected at its lower end with the end of one of the keys *h*, (*fig.* 6,) and therefore deſcends when the oppoſite extremity of the key is lifted up by the pins of the barrel. This detent has two hooks at its upper end, which can be occaſionally brought to engage either of the two pins projecting from the two arms, 26 and 27, of the tumbler; but as theſe two are on oppoſite ſides of the centre of motion *v*, it is evident that, by being hooked on one, it will, when depreſſed by the key, turn the ſpindle, *v*, one way, and ſhut the ſtop, but being hooked on the other pin, the ſame motion of the key will produce an oppoſite effect on the ſpindle, and open the ſtop. The detent is made to ſhift itſelf every time it is acted upon in this manner: the upright arm, 29, of the tumbler has a projecting claw, which is cleft for the reception of a light ſpring, 30, affixed to the lower part of the detent 28, and when at liberty ſtanding ſtraight in the direction of its length. Now ſuppoſe the parts in the poſition of *fig.* 13, the hook of the detent is over the pin, 27, of the tumbler: in this ſtate, if the detent is drawn down by the key, it depreſſes the arm 27, and throws the arm, 29, over to the oppoſite ſide, as ſhewn in *fig.* 12, carrying the end of the ſpring, 30, with it, and bending it. Now the inſtant the preſſure of the key is relieved, the ſpring throws the detent over to the other arm, 26, of the tumbler, and it is ready the next time it is acted upon by the key, to return the ſtop to its original poſition.

As it is neceſſary, when the barrel commences a piece of muſic, that the whole number of ſtops ſhould be open, the lever 40 (*figs.* 8 and 10.), is fixed on the ſpindle *q q*, and has a rod, extending beneath the inſtrument to the right-hand end: there it operates upon a lever, ſituated on a horizontal ſpindle, carrying as many arms as there are ſtops. Theſe, when the barrel is ſhifted by the knob 15, as before explained, puſh in the whole of the ſtops at once.

There are four ſtops or ranges of pipes, which are excluſively appropriated to the barrel, in addition to the ten ſtops which belong to the finger-keys. Theſe are called the ſtop-diapaſon accompaniment, which are wooden pipes to be uſed in concert with the ſtop diapaſon; the flute ſtop, which conſiſts of ſmall wooden pipes; as are alſo the pipes of the flageolet ſtop; laſtly, the trumpet ſtop, which conſiſts of metal pipes with reeds, conſtructed as ſhewn at *fig.* 5.

Our readers will now have a good idea of the mode of action of the barrel. The key-frame, as ſhewn in *fig.* 6, contains 102 keys; 88 of them being connected with the valves in the wind cheſt, and the remaining 14 for the ſtops: theſe are all ſituated towards the left-hand end, becauſe, as ſhewn in *fig.* 2, the wires for the valves are there at ſo great a diſtance aſunder, as to admit the ſtop-keys to be placed in the ſpaces between the valve-keys. The barrel has 102 circles of pins in action at the ſame time, and eight times as many, *viz.* 816, upon its circumference, containing eight different tunes, as before deſcribed; any one of which can be played by ſhifting the ſnail-wheel 10. There is a ſmall dial in front of the organ, with an index, which ſhews what tune the barrel is ſet for: it is on the oppoſite ſide to the wind-dial *y* (*fig.* 1.), and its motion is communicated from the wheel 11, by a lever and detent. On turning the handle *w*, the endleſs ſcrew, 2, gives motion to the ſpindle 4, and that turns the barrel with a very regular motion, becauſe of the fly-wheel *x* (*fig.* 1.)

As

As the pins in the barrel paſs by the keys, they lift them up at the proper intervals of the tune; and many are made like ſtaples, with a long ſhank, ſo as to hold a note, by keeping up the key for ſome time. All this time the ſtops are, by the tumblers (*figs.* 12 and 13), as before mentioned, brought on and off to give all the variations, in a full piece of muſic, and introduce the different inſtruments which are imitated by the pipes of the ſeveral ſtops, giving the inſtrument the effect of a whole band of performers, and that with a preciſion of time and harmony ſeldom to be met with in a concert. The formation of theſe barrels (for the inſtrument has ſeveral different ones which can be put in) is a moſt delicate mechanical operation, and requires a good knowledge of muſic. Meſſrs. Flight have improved this branch of the art, by the introduction of mechaniſm for actuating the ſtops, and alſo by ſome mechanical contrivances, for dividing and ſetting out the barrels more accurately than they are uſually done.

It will be evident that, on a barrel ſuch as we have deſcribed, no piece of muſic of great length can be performed; becauſe when the barrel has made its revolution, the ſame tune is repeated. But to give the inſtrument the power of performing very long pieces, ſpiral barrels are introduced: in theſe, the pins, inſtead of being arranged in 816 circles, are diſpoſed in 102 ſpiral lines, each making eight turns upon the barrel, which, as it revolves on its axis, alſo traverſes end-ways, thus bringing the ſpiral lines conſtantly beneath the keys; ſo that the barrel admits of making eight revolutions, before it repeats the ſame tune. It is evident that ſuch a barrel cannot be ſhifted to produce different tunes, as in the former caſe, its circumference being wholly occupied by one piece, if it is very long; or it may be made to contain two, three, or four ſhorter pieces: but ſtill they muſt follow in ſucceſſion upon the ſame ſpiral lines, and will come after each other, in turning the barrel, without any ſhifting. When a ſpiral barrel is put into the inſtrument, the ſnail-wheel, 10, is detached from its ſpindle, as it can be of no uſe: inſtead of it, the arbor or pivot of the barrel has a ſcrew or worm 34, (*fig.* 14.), fixed upon it; the interval of its threads correſponding in diſtance with the ſpiral lines upon the barrel; ſo that a fixed piece of ſteel, being held in the groove of the ſcrew, will, when the barrel is turned round, cauſe it to traverſe at the ſame time it revolves. This fixed piece of ſteel is attached to a projection of a piece of braſs, 31, 32, 33, called the thumb-piece: it ſupports the ſpindle of the ſnail-wheels, 10 and 11, before deſcribed; but having no motion in the uſe of the plain barrel, was then conſidered as a fixed piece; it is in reality attached to the key-frame thus: it has an arm 32, (*fig.* 7.) proceeding from it, which at the extremities turn up into joints, 32, 32; theſe are received into ſimilar joint pieces of braſs, ſcrewed to the key-frame T, ſo ſituated that the joints are exactly in the line of the centre of motion for the key-frame, ſo that the thumb-piece has liberty to riſe and fall on the ſame centre of motion as the key-frame; but being attached to it by a long firm axis, 32, 32, it has no other motion than upon this centre. A wire 37, (*fig.* 7.) is jointed to the thumb-piece 31, and, paſſing through a hole in the key-frame, has a nut ſcrewed upon it: this is ſo adjuſted, that the key-frame may be lifted up a ſmall quantity, without raiſing the thumb-piece; but after this, the nut lifts it up. By this means the key-frame will always be lifted up, to clear the points of the keys from the pins, before the edge, 33, quits the groove of the ſcrew, and ſuffers the barrel to ſhift end-ways.

Suppoſe the barrel put into its place, and thruſt towards the left hand, as far as it will go, the edge, 33, of the thumb-piece is inſerted into the groove of the ſcrew, as ſhewn in *fig.* 14; the key-frame let down, and all is ready to begin, from the commencement of the piece of muſic. On turning the handle, the barrel revolves, and at the ſame time traverſes, by the ſcrew 34, till it has made eight turns, and come to the end of the piece; the end of the ſcrew, 34, having come to the edge of the thumb-piece 33, the barrel muſt be returned to its firſt poſition, to repeat the muſic. It does this itſelf by the following means: a projecting pin, 35, is fixed in the right-hand end of the barrel, at ſuch a diſtance from the centre, that it will intercept the end of a catch, 36, fixed to the key-frame; but it paſſes clear, by the ſide of this catch, at every revolution but the laſt, when the ſcrew has traverſed the barrel ſo far as to bring the pin, 35, into the plane of the catch 36. This happens at the moment the piece is finiſhed; and as the barrel turns, it lifts up the key-frame, and raiſes the keys clear, ready for the barrel to return: the pinion, 4, is at the ſame time diſengaged by the levers, 24, 25, as before deſcribed. The keys having riſen ſufficiently for this purpoſe, the wire, 37, lifts up the thumb-piece, ſo that its edge, 33, leaves the ſpiral groove of the ſcrew, and nothing now prevents the return of the barrel by the action of the ſpring-piece 9, which always preſſes on the left-hand pivot. But as the key-frame would deſcend the inſtant the pin 35, in the end of the barrel, quits the catch 36, another catch, 38, at the other end, is introduced: this holds up the key-frame until the barrel has completed its return. The end of it then ſtrikes the lower end of the catch: this ſuffers the key-frame to deſcend, and the edge, 33, of the thumb-piece enters the groove of the ſpiral at its commencement, ready to repeat the tune: the catch, 38, has a ſcrew through the lower end, upon the head of which the barrel ſtrikes; this admits of adjuſtment, ſo that the edge, 33, ſhall fall, when the groove of the ſcrew is preciſely beneath it.

We have been thus particular in our deſcription of this ſuperb inſtrument, not leſs on account of its mechanical ingenuity, than from the great celebrity it has obtained from the firſt profeſſors of muſic, who have frequently borne teſtimony to its evident ſuperiority over any thing of the kind before produced; and allowed that mechaniſm has, in this inſtance, become a moſt powerful rival of the beſt execution on finger-keys.

His royal highneſs the prince regent lately dined with lord Kirkwall, and a ſelect party of nobility. During the deſert they were entertained by the performance of the celebrated opera of Mozart's, the Zauberflute, by the barrel part of this inſtrument, followed by the march, in the ſame piece. The machine produces the various accompaniments of a whole band of muſic, in ſuch dulcet as well as forcible tones, that no one would credit without an opportunity of hearing it.

The inventor then played various pieces on the finger-keys, one peculiarly adapted to diſplay the rich, mellow ſounds of the bugle horn; then produced a ſimilar imitation of French horns and baſſoons, with echoes to each, which were exactly as if they replied from the oppoſite ſide of a river to the original notes ſounded in the room. Theſe magic effects are chiefly produced by the ſwell, which gives to the organ all the variation of ſoftneſs or loudneſs, imitating at pleaſure the ſounds of violins, or bowed inſtruments, in the moſt ſtriking manner, but rather by aſſociation than reality, becauſe thoſe are the inſtruments from which we are accuſtomed to hear the alternation from ſoft to powerful tones, in the greateſt perfection.

The organs of which we have been ſpeaking, however ſimple or complex as to their number of ſtops, or ranges of keys,

keys, &c. have but twelve finger-keys in each octave, and theſe are generally tuned to what is called the *mean-tone* ſyſtem, that is, eight of the major thirds, *viz.* on C, G, D, A, E; F, ♭ B, and ♭ E, are made perfectly in tune, or very nearly ſo, and four of the thirds, *viz.* upon B, ♯ F, ♯ C, and ♯ G, remain each, unavoidably, too ſharp, by an enharmonic dieſis (or near it), which ſome call a quarter of a tone, and conſequently, ſuch thirds *beat* very faſt. The organ in the Temple church, London, has fourteen ſounds, and as many finger-keys in each of its octaves; the performer has it therefore in his power to avoid or remedy the firſt of the above falſe thirds, by ſubſtituting ♯ D, inſtead of ♭ E, and the laſt of theſe (below C), in ſome caſes, by the uſe of ♭ A inſtead of ♯ G. Theſe ſubſtitutions the Temple organiſt is enabled to make during performance, owing to the ſhort key between D and E being divided in its length, the longer or front half of it touching ♯ D, and the ſhorter or back half ſounding ♭ E. In like manner the ſhort key between G and A is divided, the front part for ♯ G, and the back part for ♭ A. This is, we believe, the largeſt number of finger-keys which remains in uſe in this, or perhaps any other country, although inſtruments have been made, and tried, with nineteen finger-keys in each octave, but playing upon them was found too difficult, if not impracticable. The Foundling Hoſpital organ, in London, has ſixteen ſounds in each of its octaves, but only twelve finger-keys, as uſual, having quarter notes, as ſome call them, for ♯ D, ♭ A, ♯ A, and ♭ D, in addition to the twelve common notes as above; and which new notes, by means of two ſtops that move ſideways, can be brought on when wanted, in order to correct all the four major thirds that are too ſharp, as above mentioned: ſtill, however, ſeveral other falſe concords occur in the uſe of this inſtrument.

The organ at Chriſtchurch, in Blackfriars road, London, has been lately erected under Mr. Hawke's patent, a copy of which will be found in the Philoſophical Magazine, vol. xxxvii. p. 323 and 325, ſee alſo vol. xxxix. p. 417. This has ſeventeen ſounds in each octave, (ſee our article HAWKE'S *Temperament*,) yet has only the twelve uſual finger-keys, ſeven of which are long ones, and five ſhort ones; the latter producing the *ſharp* notes, unleſs that a pedal is preſſed, which flattens each of theſe notes a dieſis, and makes them all *flat* notes.

The organ which Dr. Kemp exhibited in his lectures at the Ruſſel Inſtitution, for which Mr. Loeſchman has a patent (ſee the Philoſophical Magazine, vol. xxxvii. p. 326, and vol. xxxviii. p. 47.) has twenty-four ſounds, and as many pipes in each octave. By the help of ſix pedals, and the twelve uſual finger-keys, the performer is enabled to execute the mean-tone ſyſtem correctly, or any other, in the twenty-four uſual keys, and very nearly ſo for all the concords that occur in thirty-three different keys.

All theſe progreſſive ſteps in the improvement of the *tune* of organs, are only applicable to the tempered ſyſtems of tuning, in which the greater part of the concords muſt ſtill be left imperfect, although the moſt improved ſyſtems have them ſo in *ſmall*, and in equal degrees, inſtead of that great and diſagreeable irregularity, which attends all the uſual modes of tuning organs with only twelve notes; we ſay uſual modes, becauſe on the organ, an *equal temperament* has certainly never been uſed, whatever may have been done on piano-fortes, and other ſtringed inſtruments, where *beats* are leſs obſervable and offenſive. In the year 1810, the Rev. Henry Liſton perfected an inſtrument, calculated to ſuperſede temperament altogether, and took out a patent for the ſame, under the name of the Euharmonic organ; which patent will be found deſcribed in the Philoſophical Magazine, vol. xxxvii. p. 328.) Since that period, Meſſrs. Flight and Robſon have completed another organ for him (Philoſophical Magazine, vol. xxxix. p. 373 and 414.), containing twenty-four pipes in each octave, and provided with eleven pedals, ſix of which, for flats and ſharps, are uſed exactly ſimilar to thoſe of Mr. Loeſchman above mentioned. This invention enables the performer to produce *perfect harmony* in every key which is in common uſe, as Mr. Liſton has fully explained mathematically, and by reference to numberleſs experiments and examples on his organ, in his "Eſſay on perfect Intonation," a work to which we wiſh to call the notice of compoſers as well as performers, as developing many of the hitherto hidden myſteries of harmony. It may be proper to add, that the twenty-four pipes of Mr. Liſton's organ, are occaſionally made to yield twenty-four other notes, which are each one comma flatter than the pitch of the pipes, and alſo eleven other notes, which are each two commas flatter than certain of the pipes; making in all fifty-nine notes in each octave; all which degrees of ſound frequently come into uſe, in the keys now commonly uſed on the organ; and in all the correct performances of violiniſts, ſingers, &c. they have always been in uſe. Theſe changes of the ſounds of his pipes, Mr. Liſton effects by ſhaders, or flat plates of metal of two different ſizes, which by means of his pedals are made to ſtand over the tops of open pipes, or before the mouths of ſtopped pipes, at the due diſtance for flattening the pipe the exact proper quantity, while it is ſo preſented to the current of air iſſuing from the pipe. The tuning of theſe organs has no difficulties, except the labour of it, becauſe not a ſingle interval requires tempering, but the whole are produced from perfect concords, without the ſloweſt perceptible *beating*, ſuch intervals as a performer uſes in tuning his violin.

In attempting to deſcribe the requiſites of a good organ, we ſhall begin with the bellows; which, beſides being of a ſize fully adequate to ſupply the chorus, ſhould at all times give an equal weight of wind. This may be known, by holding down two notes of the diapaſon, or any other ſtop, when the bellows are nearly full, and obſerving whether they continue in the ſame relative ſtate of tune, until the bellows are nearly empty. If they do, the wind is equal; without which no organ can ever be in tune: alſo, when carefully blown, no difference ſhould be heard from the action of blowing. In like manner, a ſingle note of the diapaſon ſhould continue unaltered in its pitch, and ſmooth in its tone, while the other ſtops are added in ſucceſſion, until the whole chorus be drawn. This proves that the wind meets with no impediment in its courſe to the pipes; a requiſite of no leſs importance than the former.

The draw-ſtops ſhould move with ſufficient eaſe and ſmoothneſs; and ſhould ſtop ſo decidedly, as to leave no doubt of their being completely drawn, or ſhut.

The touch of the keys ſhould be free and elaſtic, and exactly the ſame preſſure ſhould be requiſite to put down every key throughout the ſcale. No better proof can be given of a good touch, than that a turned ſhake can be executed with equal facility in every part of the ſcale, except perhaps in the loweſt octave, where it is not to be expected or deſired. If all theſe things act without noiſe, the mechanical parts of the organ may be conſidered good, and in order.

The goodneſs of the pipes is not ſo eaſily deſcribed, becauſe much depends upon the quality of the tone, of which little idea can be given in words. A fine quality and great ſtrength can hardly be expected from the ſame pipe: it, therefore, depends ſomewhat on choice which to prefer; though it does not follow that all ſoft-toned pipes are of a fine quality. But be the quality what it may, it ſhould be uniform from the top to the bottom; a requiſite which cannot be too ſtrongly inſiſted on in all inſtruments, ſo as to

give the idea of all the notes coming from the ſame pipe or ſtring.

It is indiſpenſable to an organ, that it have a good ſtopped diapaſon, as that ſtop is the foundation of the organ, and is never ſhut, except when the dulciana or flute are uſed as ſolo ſtops. It is of great importance that it be ſufficiently full and bold in the baſe, particularly in thoſe chamber organs which have an open diapaſon; as that ſtop is ſeldom extended lower than G gamut. And in large church organs, where the open diapaſon goes through the ſcale, the lower notes are feeble, if not ſupported by the ſtopped diapaſon; and it may be obſerved, that no ſtop ſhould be loudeſt at the top. Of the open diapaſon, little more need be ſaid than that it ſhould be full, ſmooth, and articulate. In ſmall organs it is entirely diſpenſed with; and in thoſe which are larger, it is in the treble only, or more or leſs extended into the baſe, according to the ſize of the organ, or choice of the builder; and it may be proper to obſerve, it is better that the loweſt pipes ſhould not be ſo loud as to make the break very perceptible. In large church organs there are frequently two open diapaſons through, and nothing can be a greater recommendation to an organ than its having good diapaſons. What has been already ſaid, will apply to all other ſtops generally, when taken ſingly; but their relative ſtrength is of great importance to the goodneſs of the chorus. As a ſingle ſtop ſhould not be loudeſt at the top, ſo the chorus ſtops ſhould not predominate over the diapaſons; a fault very general in the old organs, ariſing from the bad taſte of the times in which they were made. The chorus ſhould be rich, brilliant, and articulate; and the twelfth and tierce, and their octaves, ſhould not be heard, except when liſtened for. The trumpet-ſtop, when good, adds greatly to the majeſty, as well as to the ſtrength of the chorus; and its octave, the clarion, increaſes its brilliancy.

The goodneſs of theſe, and all other reed ſtops, beſides the requiſites already mentioned, depends upon their ſpeaking readily and quickly; and being free from the naſal tone, ſuch as is produced by bad players on the clarionet, or hautboy. And it had been well if the trumpet had never been uſed as any other than a chorus-ſtop; for its uſe, as an imitation of a real trumpet, has given riſe to the introduction of a variety of imitation-ſtops; moſt of them a diſgrace to the noble inſtrument in which they are ſuffered to intrude; and its conſequence, a trifling and vitiated ſtyle of performance, equally diſgraceful to the taſte of this country, where only it is cultivated.

ORGAN, *Hydraulic*, denotes a muſical machine that plays by means of water inſtead of wind.

Of theſe there are ſeveral in Italy in the grottos of vineyards.

Cteſebes of Alexandria, who lived in the reign of Ptolemy Euergetes, is ſaid to have firſt invented organs that played by compreſſing the air with water, as is ſtill practiſed. Archimedes and Vitruvius have left us deſcriptions of the hydraulic organ. Felibein, de la Vie des Archit. See Hawkins's Hiſt. of Muſic, vol. i. p. 190, &c. See HYDRAULICON.

In the cabinet of queen Chriſtina is a beautiful and large medallion of Valentinian, on the reverſe of which is ſeen one of theſe hydraulic organs; with two men, one on the right, the other on the left, ſeeming to pump the water which plays it, and to liſten to its ſound. It has only eight pipes placed on a round pedeſtal. The inſcription is PLACEA SPETRI, if it be not wrong copied, which we ſuſpect.

ORGANICAL, in the *Greek Muſic*, was ſynonimous with inſtrumental, or muſic played by inſtruments, which had a notation in characters different from the vocal, as may be ſeen in Bacchius and Alypius. See GREEK *Muſic*, and CHARACTERS.

ORGANICAL, or *Organic Diſeaſes*, are thoſe diſeaſes in which the ſtructure of ſome organ of the body is actually deranged, and its functions conſequently impeded.

Diſorder of function, however, does not neceſſarily imply derangement of ſtructure: all diſeaſes, therefore, are not organic. Diſeaſed *action* of the vital and irritable parts will be attended with a diſordered ſtate of the functions, as well as diſeaſed *ſtructure* of the parts themſelves; and it is extremely important to diſtinguiſh between theſe two ſources of morbid ſymptoms. For the diſeaſes, which ariſe from the former ſource, are generally within the ready controul of medicine; whilſt thoſe, which originate from morbid ſtructure, are commonly beyond the reach of art; or at leaſt palliation of the ſymptoms, and the retardation of the progreſs of the morbid condition, are all that art can effect, except in the early ſtage of ſtructural change.

This ſtatement may be illuſtrated by a view of the diſeaſes of the ſtomach; ſome of which are the reſult of morbid action of the muſcular coat, or of the ſecretory veſſels, excited by irritation in the organ itſelf, or by ſympathy with ſome other organ; and ſome ariſe from actual organic changes of ſtructure in the ſubſtance of the viſcus. Thus pain and ſickneſs, amounting even to vomiting, may be excited, in a very irritable condition of the ſtomach, by the ordinary food, or by any ſubſtance which is acrid, or not eaſily digeſted: this irritability, again, may be occaſioned by a particular ſtate of the nervous ſyſtem in general, or of that of the ſtomach in particular, or it may be merely ſympathetic of a diſeaſed condition of the brain, or of a calculus in the kidnies, &c. Under any of theſe circumſtances, the diſorder of the ſtomach is not organic; there is no derangement of its ſtructure, nothing which the eye could detect, if it had acceſs to the interior parts of the body; and the morbid action of the organ may be perfectly cured, either by diminiſhing the general or local exceſs of irritability, by appropriate medicines, or by curing the diſeaſes of the brain, the kidney, &c., of which the ſtate of the ſtomach is merely ſympathetic. But, on the other hand, pain and ſickneſs in that organ may be connected with a morbid change in its ſtructure; as, for example, with a chronic inflammation of its coats, or with a ſcirrhous or cancerous ſtate of the organ, eſpecially about the pylorus, or paſſage into the bowels. Scirrhus or cancer of the ſtomach, as of other organs, is ſcarcely within the power of medicine, the object of which is, therefore, limited to an alleviation of the ſymptoms, by means of anodynes, light, liquid, and digeſtible diet, in ſmall quantities, and laxatives.

Organic diſeaſes are not always diſtinguiſhable, in their commencement, from mere diſorders of function. They often proceed for a conſiderable time, without any great derangement of the functions themſelves, and with intervals even of total freedom from any morbid ſymptoms; ſo that they are often only diſcovered to be organic, by the pertinacity with which they continue, until at length, not only the functions of the diſeaſed organ are greatly impaired, but a hectic or habitual fever comes on, the ſtrength ſinks, and general emaciation evinces the failure of the functions of nutrition, which a fixed diſeaſe in any important organ ultimately produces.

It is only upon diſeaſes that are organic, that diſſection after death throws any light: and it has taught us to connect certain ſymptoms during life, with certain changes of ſtructure in particular organs; inſomuch that a ſkilful obſerver will commonly be able, from marking the ſymptoms, to point out the organ diſeaſed, and the nature of the morbid change that is going on. Hence the obvious value of *morbid anatomy*,

anatomy, as it has been called, to the phyſician. Nevertheleſs, it is to be lamented, that this value is of leſs practical importance than it ſeems to be at firſt ſight: for the animal machine differs materially from all other mechaniſm, inaſmuch as we have not the means of replacing the parts that are become uſeleſs or decayed, nor even of rectifying the derangement of ſtructure, which we know has taken place, if it have already made any conſiderable progreſs. The principal practical advantage, derived from ſuch knowledge, conſiſts in the early detection of incipient organic diſeaſe, while its progreſs may yet be arreſted, and in the prevention of all violent meaſures, in the later ſtages, when palliation is all that can be hoped for. For although much alleviation of pain and ſuffering is within the power of art, yet much injury may ſometimes reſult from the fruitleſs adminiſtration of ſtrong medicines.

The various organic diſeaſes of the body, will be found deſcribed under their reſpective appellations.

Organical *Deſcription* of curves is the method of deſcribing them on a plane by means of inſtruments. See Curve.

Organical *Part*, is that part of an animal or plant deſtined for the performance of ſome particular function. See Organ.

Organical *Parts*, in Buffon's ſyſtem of generation. See Generation.

ORGANISER *le Chant*, in the beginning of counterpoint, was to introduce ſome thirds at the cloſes of a chant in uniſon: for example, when one part of the chorus ſung C, D, B, C, the other ſung at the ſame time C, D, D, C. It appears by theſe examples, cited by the abbé le Bœuf, and by others, that organiſation was ſeldom practiſed except upon the ſharp 7th, or note ſenſible at a cloſe; hence it follows, that it was always the minor third which conſtituted this new harmony. For a concord ſo eaſy, and affording ſo little variety, the fingers who organiſed had a particular remuneration. With regard to the *organum triplum*, or *quadruplum*, which was alſo ſimply called *triplum* or *quadruplum*, it was nothing elſe but the ſame chant with the parts organiſed with the counter-tenor in the octave to the baſe, and by the treble in the octave to the tenor.

ORGANNA, in *Geography*, a town of Spain, in the province of Catalonia; 18 miles N. of Solſona.

ORGANO, in Corelli's concertos, and in general all concertos compoſed in Italy for the church, is the ripieno baſe appropriated to the organ.

ORGANZINE, in the *Silk Trade*. See Silk.

ORGAS, in *Geography*, a town of Spain, in New Caſtile; 12 miles S.S.E. of Toledo.

ORGASM, οργασμος, denoting violence, or turgeſcency; formed from οργαω, *turgeo*, *I ſwell*, an ecſtacy or impetuous deſire of coition, occaſioned by a turgeſcency of the ſeminal veſſels, which are no longer able to reſtrain their contents.

The ancients alſo extend orgaſm to the other humours, and even excrements, which being accumulated, and coming to ferment, demand excretion.

Quincy uſes orgaſm for an impetuous or too quick motion of the blood, or ſpirits; by which the muſcles are diſtended with an uncommon force.

ORGE, L', in *Geography*, a river of France, which runs into the Seine, 30 miles S. of Paris.

ORGELET, a town of France, in the department of the Jura, and chief place of a canton, in the diſtrict of Lons-le-Saulnier; 12 miles S. of it. The place contains 1224, and the canton 10,014 inhabitants, on a territory of 245 kiliometres, in 40 communes. N. lat. 45° 31'. E. long. 5° 41'.

ORGE'RES, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the diſtrict of Chateaudun; 12 miles S.W. of Janville. The place contains 286, and the canton 6927 inhabitants, on a territory of 310 kiliometres, in 18 communes.

ORGIA, a town of Etruria; ſix miles S.W. of Sienna.

Orgia, οργια, in *Antiquity*, feaſts and ſacrifices performed in honour of Bacchus, inſtituted by Orpheus, and chiefly celebrated on the mountains by wild, diſtracted women, called *Bacchæ*.

Euſebius derives the word απο της οργης, *fury*, *madneſs*.

Others from ορος, *mountain*; becauſe Orpheus removed from Thrace to mount Citheron: others from οργας, a place conſecrated to ſome divinity: others from ειργαν, *to remove*, *to repulſe*; in regard the profane were to be driven away.

The orgia were alſo called Orphica, from their inſtitutor; and Bacchanalia, Dionyſia, and Liberalia. It is a fact agreed upon by both mythologiſts and antiquaries, that the orgies derived their original from Egypt; and that they owe their inſtitution to Iſis, who having recovered the diſſipated members of her huſband, murdered by the conſpirators, headed by Typhon his brother, and being unable to find the virile parts, which the fiſhes of the Nile had devoured, conſecrated the repreſentation of them, which the prieſts in after times carried about in the feſtivals inſtituted in honour of that prince. It is alſo another allowed fact, that Orpheus and Melampus, in their travels to Egypt, had ſeen the feſtivals of Oſiris celebrated, and introduced them into Greece. Bacchus, it is ſaid, in honour of whom the orgies were celebrated, is the ſame with Oſiris. From Greece the orgies paſſed into Phrygia; and the knowledge of them was brought into Italy, either by the Arcadians, when they planted a colony in Latium, or by Æneas himſelf with his Trojans, who had previouſly celebrated this feſtival

They were held every third year. The chief ſolemnities were in the night-time; and were attended with all manner of impurities.

They were carried to ſuch an exceſs, that in the year of Rome 568, the ſenate was obliged to aboliſh them through the whole empire. And Cicero informs us, that Diagondas aboliſhed theſe infamous feſtivals at Thebes.

The women who preſided over theſe feaſts were called Orgiaſtæ: and the men who performed the ſame office were denominated Orgiophantæ.

Servius ſays, that at firſt orgia was a common name for all kinds of ſacrifices among the Greeks, of the ſame import with the word *ceremoniæ* among the Romans.

ORGITANO, in *Biography*, a Neapolitan performer and compoſer for the harpſichord in 1770, the beſt which Naples could boaſt; but, as a player, much inferior to many at that time in England; and as a compoſer, he was ſurpaſſed, both in force and good taſte, by thouſands in Germany. But the Neapolitans, ſince the time of Memo Scarlatti, have never piqued themſelves on inſtrumental excellence. Vocal compoſitions and vocal perfection in performance, are the grand deſideratum, not only at Naples, but of all Italy.

ORGON, in *Geography*, a river of Chineſe Tartary, which riſes in N. lat. 46° 56'. E. long. 101° 20', and runs into the Selingue, N. lat. 50°. E. long. 106° 14'. Near this river, in N. lat. 48° 57'. E. long. 104° 36', an aſſembly of the Kalkas Tartars was held in 1698.—Alſo, a town of France, in the department of the mouths of the Rhone, and chief place of a canton, in the diſtrict of Taraſcon; 17 miles E. of Taraſcon. The place contains 2401, and the canton 9401 inhabitants, on a territory of 235 kiliometres, in eight communes.

ORGUES, in *Fortification*, thick long pieces of wood,

pointed and ſhod with iron, and hung each by a ſeparate rope over the gateway of a city, ready on any ſurprize or attempt of the enemy to be let down to ſtop up the gate.

The ends of the ſeveral ropes are wound round a windlas, by means of which they may be all let down together.

Orgues are preferable to herſes, or portcullices, becauſe theſe may be either broke by a petard, or they may be ſtopped in their falling down; but a petard is uſeleſs againſt an orgue; for if it break one or two of the pieces, they immediately fall down again, and fill up the vacancy; or if they ſtop one or two of the pieces from falling, it is no hindrance to the reſt; for being all ſeparate, they have no dependence upon one another.

Orgues are alſo uſed for a machine compoſed of ſeveral harquebuſs or muſquet-barrels, bound together; by means of which ſeveral exploſions are made at the ſame time; uſed to defend breaches, and other places attacked.

Orgues, *des*, Fr. (See Organ.) The firſt organ that was ſeen in France, and ſent to king Pepin, cauſed great aſtoniſhment. Charlemagne, the ſon of Pepin, received another from the emperor Michael. Eginard ſays that this was an hydraulicon. In the eccleſiaſtic interdictions the organ uſed to be ſilenced.

Organs were admitted into convents about the tenth century. In the time of St. Louis, every ſpecies of wind inſtrument had admiſſion in the divine offices. We read in the annals of this prince, how devoutly he cauſed the maſs to be ſung, and the whole ſervice *à chant et à déchant, à ogre et à triple*, with the organ and trumpet.

ORGYA, ὀργυια, an ancient Grecian meaſure, containing ſix feet.

Some repreſent the orgya as the Grecian pace.

Heſychius deſcribes it as the ſpace comprehended between the two hands, when the arms are extended; anſwering to the Roman ulna, and our fathom.

ORHAI, in *Geography*, a town of Moldavia, on the Reut; 66 miles E.N.E. of Jaſſi.

ORI, a town of Sardinia; 8 miles S. of Saſſari.

ORIA, a town of Spain, in the province of Granada; 19 miles S. of Hueſca.

Oria, or *Oira*, a town of Naples, in the province of Otranto; the ſee of a biſhop united to Tarento: founded by a colony of Cretans. Here Servilius, one of the officers of Octavius Cæſar, was ſurpriſed by Mark Antony; 45 miles N.W. of Otranto.

ORIAGO, a town of Italy, in the Paduan, on the Brenta; 12 miles E. of Padua.

ORIBASIA, in *Botany*. See Psychotria.

ORIBASIUS, in *Biography*, an eminent phyſician of the fourth century, was born at Pergamus, or, as ſome have aſſerted, at Sardes, where he reſided for ſome time. He was educated at the ſchool of Zeno the Cyprian, who appears to have taught at Sardes at that time, though he afterwards became one of the moſt celebrated profeſſors of Alexandria. Oribaſius is mentioned by his contemporary, Eunapius, as one of the moſt learned and accompliſhed men of his age, and the moſt ſkilful phyſician; and his talents and agreeable manners not only raiſed him to great public reputation, but obtained for him the friendſhip of the emperor Julian, who appointed him quæſtor of Conſtantinople. His elevation, and his ſteady adherence to the principles of Julian, however, procured him many enemies; and after the death of that prince, in the year 363, his fortune ſuffered a ſevere reverſe. Perſecution was carried againſt him ſo far, that he was ſtripped of his property, and, under Valentinian II., was ſent into baniſhment among the Barbarians. He ſuſtained his misfortunes with great fortitude; and the dignity of his character, together with his ſingular profeſſional ſkill and kindneſs, gained him the reſpect and veneration of theſe rude people, among whom he was adored as a tutelary god. At length, however, he was recalled to the imperial court, and regained the public favour. Eunapius repreſents him as again flouriſhing in wealth and reputation at Conſtantinople, at the time when he wrote the lives of the philoſophers, which was near the year 400.

Oribaſius was principally a compiler; but, on certain practical points, as Freind obſerves, he has made ſome valuable remarks, which are not to be found in preceding writers. At the requeſt of the emperor Julian, he made an extenſive compilation from Galen and all the other preceding medical authors, in ſeventy, or according to Suidas ſeventy-two books, which are entitled his "Collections." But of theſe only the firſt fifteen books remain, together with two others, which are called by Raſarius, his tranſlator, the 24th and 25th of the ſeries, and which treat of anatomy. In this work are preſerved many paſſages of ancient writers not to be met with elſewhere, and others are given with more accuracy than in the extant works of the authors themſelves. He afterwards drew up an epitome, or "Synopſis" of this great work, for the uſe of his ſon Euſtathius, reducing the whole to nine books. This ſynopſis is ſtill extant; as well as four books, on medicines and diſeaſes, addreſſed to his friend Eunapius, entitled "Euporiſtorum, *i. e.* paratu facilium, &c. Libri." Photius mentions two other works of Oribaſius, that were extant in his time, one conſiſting of four, the other of ſeven books, which were merely an epitome of Galen's works and dedicated to Julian. This epitome is mentioned by Paulus; but it is now loſt, as well as ſome other tracts mentioned by Suidas. The theoretical and anatomical parts of the writings of Oribaſius are almoſt purely tranſcripts from thoſe of Galen; whence he has been by ſome nicknamed Galen's ape But although his books do not contain a great deal that is original, and did not perhaps contribute to the advancement of the art, yet they rank among the more valuable of the medical works of antiquity. He was a great collector of recipes and ſpecific remedies, many of which were afterwards received upon his authority. He ſpeaks in terms of much praiſe, however, of the ſucceſs of local evacuations of blood, eſpecially by ſcarifications, a practice which had not been much noticed by preceding writers. He employed this remedy in ſuppreſſion of the catamenia, in head-ache, inflammation of the eyes, difficulty of breathing, &c. even in perſons of advanced age; and he affirms, that he was himſelf cured of the plague by it, when it raged in Aſia, having loſt two pounds of blood from the thighs, on the ſecond day of the diſeaſe. Oribaſius firſt deſcribed a ſingular ſpecies of inſanity, which he called *lycanthropia*, in which the patient wanders about by night among the tombs, as if he were transformed into a wolf. His full and curious deſcription of this diſeaſe has been copied by Paul, Actuarius, and others, without addition or alteration, and ſeems to relate to that ſpecies of melancholy, which occurred in the demoniac, mentioned in the New Teſtament, who abode among the ſepulchres.

Various editions and Latin tranſlations of the writings of Oribaſius have been publiſhed at different times and places. The whole works were printed at Baſle, in three volumes folio, in 1557, and in the "Artis Medicæ Principes" of Stephanus. The commentaries on the aphoriſms of Hippocrates, which were publiſhed under his name by Guinther, are obviouſly ſpurious, as Dr. Freind has ſhewn; and the two little tracts, "De Laqueis et Machinamentis," collected from Heracles and Heliodorus, are ſomewhat doubtful. See Freind, Hiſt. of Phyſ. Gen. Biog. Eloy Dict. Hiſt. de la Med.

ORICHALCUM, or AURICHALCUM, braſs. See BRASS.

It is evident, from all accounts, that the orichalcum of the ancients was a fictitious ſubſtance, not a natural metal. They made it on the ſame baſis that we make braſs at preſent; but they had ſeveral ways of doing it, and diſtinguiſhed it into ſeveral kinds. They had a white ſort in frequent uſe and great eſteem; and even the yellow they diſtinguiſhed into two principal ſorts, under different names. The orichalcum and æs flavum, braſs and yellow copper, are with us ſynonimous terms, but with them they were uſed to expreſs different combinations of the ingredients.

ORICHALCUM, or *Aurichalcum album*, *white braſs*. This was a metal well known among the ancients, and celebrated by Ariſtotle and by Strabo, and others, under the name of κραμα λευκον. It was made by mixing an earth with copper, while in fuſion; but what that earth was, we are not informed.

None of our methods ſeem to be the ſame with their's, ſince the metal is debaſed by all our's, and becomes brittle; whereas in their management, according to their own accounts, it ſeems not to have loſt any thing of its ductility, though it acquired a peculiar brightneſs.

ORIEL WINDOW, in *Architecture*, a projecting angular window, moſtly of a triagonal or pentagonal form, and divided by mullions and tranſoms into different bays and other compartments. Theſe windows are not peculiar to the pointed ſtyle, as in the barbarous ſtyle which ſucceeded it, during the reigns of Elizabeth and James I., they became ſtill more common than they had been before in the pointed ſtyle.

ORIENT, ORIENS, in *Geography* or *Aſtronomy*, the eaſt, or eaſt point of the horizon.

It is thus called from the Latin, *oriri*, *to ariſe*; becauſe it is in this point the ſun riſes.

ORIENT, *Equinoctial*, is uſed for that point of the horizon wherein the ſun riſes when he is in the equator, or when he enters the ſigns Aries and Libra. See SPRING and AUTUMN.

ORIENT, *Æſtival*, is the point wherein the ſun riſes in the middle of ſummer, when the days are longeſt.

ORIENT, *Hybernal*, is the point where the ſun riſes in the middle of winter, when the days are ſhorteſt.

ORIENT, *L'*, in *Geography*, a ſea-port town of France, and the principal place of a diſtrict and ſeat of a tribunal, in the department of the Morbihan, ſituated at the mouth of the river Scorf, and built in the year 1720. The harbour is good, but not capable of receiving many ſhips of war. The town contains 19,922, and the two cantons 24,722 inhabitants, on a territory of 87½ kiliometres, in three communes. N. lat. 47° 45'. E. long. 3° 16'.

ORIENTAL, ſomething ſituated towards the eaſt with regard to us: in oppoſition to *occidental*.

In this ſenſe we ſay, oriental pearls, *q. d.* ſuch as are found in the Eaſt Indies. (See PEARL.) Oriental languages, meaning the Hebrew, Syriac, Chaldee, and Cophtic. (See LANGUAGE.) In aſtronomy a planet is ſaid to be oriental, when it appears in the eaſt before the ſun. See RISING.

ORIENTAL *Bezoar*. See BEZOAR.

ORIENTAL *Bibles*. See BIBLE.

ORIENTAL *Emerald*. See EMERALD.

ORIENTAL *Philoſophy*, is ſometimes uſed for the philoſophy of the Eaſt, or that of the Perſians, Chaldæans, and Arabians, &c. See ARABIAN, BARBARIC, CHALDÆAN, PERSIAN, &c. *Philoſophy*. See alſo BRACHMANS, EGYPT, MAGI, &c. It appears, from adverting to the hiſtory of the ancient philoſophy of the Eaſt, that, from the moſt remote times, the Oriental philoſophers endeavoured to explain the nature and origin of things by the principle of *emanation* (which ſee), from an eternal fountain of being. That through ſucceeding ages this doctrine remained, and was taught in ſchools of philoſophy in the more civilized regions of Aſia and Africa, is highly probable from various conſiderations. Nevertheleſs, this ſpecies of philoſophy did not exiſt under any diſtinct name, nor can it be referred, with certainty, to any ſingle author or leader; but a certain metaphyſical ſyſtem, chiefly reſpecting the derivation of all natures, ſpiritual and material, by emanation from the firſt fountain, was before the commencement of the Chriſtian era taught in the Eaſt, whence it gradually ſpread through the Alexandrian, Jewiſh, and Chriſtian ſchools. It is well known, that at the riſe of the Grecian ſects, the eaſtern countries were frequently viſited by the ſages who travelled in ſearch of wiſdom. We learn from Clemens Alexandrinus (Stromat. lib. i.), who was well acquainted with Oriental hiſtory, that the Greeks borrowed what was moſt valuable in philoſophy from barbarians; for philoſophy was publicly taught by the Brachmans, the Odryſii, the Getæ, the Chaldæans, the inhabitants of Arabia Felix and Paleſtine, the Perſians, and many other nations. Amongſt the Grecian philoſophers who travelled into the Eaſt was Democritus, who viſited Perſia, after the ſchools of the Magi had been reformed by Zoroaſter, and travelled to Chaldæa, and other eaſtern countries, for the ſake of learning philoſophy. Of the nature of the philoſophy which Democritus and others found in theſe ſchools, we obtain ſome idea from the declaration of Pliny (Hiſt. Nat. c. 30.), who ſays of Democritus, that he undertook, what might be more properly called an exile than a journey, for the purpoſe of learning "magical philoſophy," and returning home, taught it, in his myſteries, from the writings of certain Oriental philoſophers, which he illuſtrated. Accordingly the philoſophy of Democritus appears to have been of two kinds; public, or that of the Eleatic ſect; and ſecret, in which he followed the myſteries of the Chaldæan, Perſian, and other eaſtern Magi. Hence we may conclude, that the Oriental philoſophy ſubſiſted, without interruption in the Eaſt, through the period of the Grecian ſects.

The uninterrupted continuance of the Oriental philoſophy may be further inferred from the ſudden riſe, and rapid ſpread, of thoſe numerous hereſies, which, under the oſtentatious name of Gnoſticiſm, over-ran the churches of the Eaſt. (See GNOSTICS.) Porphyry, in his preface to a work of Plotinus againſt the Gnoſtics, ſays, that there were at that time many heretics, among whom were ſome, who, deriving their hereſy from the "ancient philoſophy," were followers of Adelphinus. From this and ſimilar paſſages it may be inferred, that prior to the appearance of the Gnoſtic hereſies amongſt the Chriſtians, a ſyſtem, well known by the name of the "ancient philoſophy," exiſted in the Eaſt; that this philoſophy is not to be ſought among the Greeks, not even in Plato himſelf, but is oppoſed to the Grecian philoſophy, as more ancient and more conſonant to the truth; that this philoſophy was commonly underſtood to have been taught by Zoroaſter; and that the Chriſtian Gnoſtics forged books, under the name of Eaſtern philoſophers, from which they pretended to derive their genealogies of emanations from the firſt fountain of intelligence. Hence alſo appears the reaſon, why Plotinus determined to ſpend eleven years in the Eaſt, "to explore the philoſophy taught among the Perſians and Indians." That the Gnoſtic hereſies were of eaſtern origin may be further concluded from other circumſtances, which it is not neceſſary now to mention. It deſerves, moreover, to be conſidered, that if all the ſyſtems of philoſophy, diſtinct from thoſe of the Grecian ſects, which became famous in

Aſia

Aſia or Egypt, particularly if the Egyptian, Cabbaliſtic, Gnoſtic, and Eclectic, be compared, there will be found among them a wonderful agreement with the general principles of that ſyſtem which we call the Oriental philoſophy; whence it ſeems reaſonable to admit the exiſtence of this philoſophy as a common ſource, and to make uſe of it as an univerſal key to unlock the myſteries of the reſt.

Upon the whole we may conclude, that the Oriental philoſophy, as a peculiar ſyſtem of doctrines concerning the divine nature, originated in Chaldæa, or Perſia; whence it paſſed through Syria, Aſia Minor, and Egypt; and mixing with other ſyſtems, formed many different ſects. There ſeems alſo to be ſufficient ground for referring the formation of the leading doctrines of this philoſophy into a regular ſyſtem to Zoroaſter, whoſe name the followers of this doctrine prefixed to ſome of their ſpurious books, and whoſe ſyſtem is fundamentally the ſame with that afterwards adopted by the Aſiatic and Egyptian philoſophers. Among the branches from the Zoroaſtrian ſtock we muſt reckon the Gnoſtic hereſies, which aroſe ſo early in the Chriſtian church. They differ materially from the Platonic doctrine from which they have been ſuppoſed to be derived, as Plotinus has fully ſhewn in his treatiſe againſt the Gnoſtics. The mixture of Platonic notions that are found in the Aſiatic philoſophy, as well as of Oriental doctrines among the later Platoniſts, may be eaſily accounted for from the intercourſe which ſubſiſted between the Alexandrian and Aſiatic philoſophers, after the ſchools of Alexandria were eſtabliſhed. From that time many Aſiatics, who were addicted to the ſtudy of philoſophy, viſited Alexandria, and became acquainted with the celebrated doctrines of Plato; and blending theſe with their own, formed an heterogeneous maſs of opinions, which in its turn mixed with the ſyſtems of the Alexandrian ſchools. This union of Oriental and Grecian philoſophy was further promoted by the diſperſion of the philoſophers of Alexandria in the reign of Ptolemy Phyſeon; many of whom, to eſcape from tyranny, fled into Aſia, and opened ſchools in many places.

It was probably at the time when the Platonic philoſophers of Alexandria viſited the Eaſtern ſchools, that certain profeſſors of the Oriental philoſophy, prior to the exiſtence of the Chriſtian hereſies, borrowed from the Greeks the name of Gnoſtics, to expreſs their pretenſions to a more perfect knowledge of the divine nature, than others poſſeſſed. That theſe philoſophers aſſumed this vaunting appellation before their tenets were transferred to the Chriſtians, may be concluded from this circumſtance, that we find it, among the Chriſtians, not appropriated as a diſtinct title to any ſingle ſect, but made uſe of as a general denomination of thoſe ſects, which, after the example of the Pagan philoſophers, profeſſed to have arrived at the perfect knowledge of God. The Pagan origin of this appellation ſeems alſo plainly intimated in two paſſages in St. Paul's epiſtles; in one of which he cautions Timothy againſt ἀντίθεσις τῆς ψευδωνύμου, "the oppoſition of falſe ſcience" (1 Tim. vi. 20.); and in the other (Coloſſ. ii. 8.) warns the Coloſſians not to be impoſed upon by a vain and deceitful philoſophy, framed according to human tradition and the principles of the world, and not according to the doctrine of Chriſt. We may conclude, upon the whole, that the tenets of the Gnoſtics exiſted in the Eaſtern ſchools long before the riſe of the Gnoſtic ſects in the Chriſtian church under Baſilides, Valentine, and others; but for want of original documents concerning the Oriental philoſophy, we can form no idea of its peculiar tenets, only by comparing the ancient doctrines of the Eaſt with that of thoſe ſects which ſpring from this ſtock. The Gnoſtics were chiefly employed in ſupporting the ſyſtem of divine emanation, taught by Zoroaſter and his followers. They maintained that all natures, intellectual and material, are derived by a ſucceſſion of emanations from the infinite fountain of Deity. From this ſecret and inexhauſtible abyſs, they conceived ſubſtantial powers, or natures, of various orders to flow; till at the remote extremity of the emanation, evil dæmons, or matter, with all the natural and moral evils neceſſarily belonging to it, were produced. Brucker's Phil. by Enfield, vol. ii.

The firſt principles of the Oriental philoſophy, as Moſheim ſtates them, ſeem perfectly conſiſtent with the dictates of reaſon; for its firſt founder muſt undoubtedly have argued in the following manner: "There are many evils in this world, and men ſeem impelled by a natural inſtinct to the practice of thoſe things which reaſon condemns; but that eternal Mind, from which all ſpirits derive their exiſtence, muſt be inacceſſible to all kinds of evil, and alſo of a moſt perfect and beneficent nature; therefore the origin of thoſe evils, with which the univerſe abounds, muſt be ſought ſomewhere elſe than in the Deity. It cannot reſide in him who is all perfection; and therefore it muſt be without him. Now there is nothing without or beyond the Deity, but matter; therefore matter is the centre and ſource of all evil, of all vice." Having taken for granted theſe principles, they proceeded farther, and affirmed, that matter was eternal, and derived its preſent form, not from the will of the ſupreme God, but from the creating power of ſome inferior intelligence, to whom the world and its inhabitants owed their exiſtence. As a proof of this aſſertion, they alleged, that it was incredible, that the ſupreme Deity, perfectly good, and infinitely removed from all evil, ſhould either create or modify matter, which is eſſentially malignant and corrupt, or beſtow upon it, in any degree, the riches of his wiſdom and liberality.

The Oriental philoſophers were divided in their opinion, when they proceeded to argue from theſe principles. Some imagined two eternal principles, from whence all things proceeded; the one preſiding over light, and the other over matter; and, by their perpetual conflict, explained the mixture of good and evil, that appears in the univerſe. Others maintained, that the being which preſided over matter was not an eternal principle, but a ſubordinate intelligence, one of thoſe whom the ſupreme God produced from himſelf. They ſuppoſed, that this being was moved, by a ſudden impulſe, to reduce to order the rude maſs of matter, which lay excluded from the manſions of the Deity, and alſo to create the human race. A third ſort fell upon a ſyſtem different from the two preceding, and formed to themſelves the notion of a triumvirate of beings, in which the ſupreme Deity was diſtinguiſhed both from the material, evil principle, and the creator of this ſublunary world. Theſe, then, were the three leading ſects of the Oriental philoſophy, which were ſubdivided into various factions, by the diſputes that aroſe, when they came to explain more fully their reſpective opinions, and to purſue them into all their monſtrous conſequences.

The diviſions among the various ſects of theſe philoſophers, did not prevent their holding, in common, certain opinions concerning the Deity, the univerſe, the human race, and ſeveral other ſubjects. They were unanimous in acknowledging the exiſtence of an eternal nature, in whom dwelt the fullneſs of wiſdom, goodneſs, and all other perfections, and of whom no mortal was able to form a complete idea. This great Being was conſidered by them as a moſt pure and radiant light, diffuſed through the immenſity of ſpace, which they called pleroma, a Greek word which ſignifies *fullneſs*; and they taught concerning him and his operations, the following things: "The eternal nature, infinitely

nitely perfect and infinitely happy, having dwelt from everlasting in a profound solitude, and in a blessed tranquillity, produced, at length, from itself, two minds of a different sex, which resembled their supreme parent in the most perfect manner. From the prolific union of these two beings others arose, which were also followed by succeeding generations; so that, in process of time, a celestial family was formed in the pleroma. This divine progeny being immutable in its nature, and above the power of mortality, was called by the philosophers, *æon*," a term which signifies, in the Greek language, an eternal nature. How many in number these *æons* were, was a point much controverted among the Oriental sages. See ÆON.

"Beyond the mansions of light, where dwells the Deity with his celestial offspring, there lies a rude and unwieldy mass of matter, agitated by innate, turbulent, and irregular motions. One of the celestial natures descending from the pleroma, either by a fortuitous impulse, or in consequence of a divine commission, reduced to order this unseemly mass, adorned it with a rich variety of gifts, created men, and inferior animals of different kinds to store it with inhabitants, and corrected its malignity by mixing it with a certain portion of light, and also of a matter celestial and divine. This creator of the world is distinguished from the supreme Deity by the name of demiurge. His character is a compound of shining qualities, and insupportable arrogance; and his excessive lust of empire effaces his talents and his virtues. He claims dominion over the new world he has formed, as his sovereign right; and, excluding totally the supreme Deity from all concernment in it, he demands from mankind for himself and his associates, divine honours.

"Man is a compound of a terrestrial and corrupt body, and a soul which is of a celestial origin, and, in some measure, an emanation from the divinity. This nobler part is miserably weighed down and encumbered by the body, which is the seat of all irregular lusts and impure desires. It is this body that seduces the soul from the pursuit of truth, and not only turns it from the contemplation and worship of the Supreme Being, so as to confine its homage and veneration to the creator of this world, but also attaches it to terrestrial objects, and to the immoderate pursuit of sensual pleasures, by which its nature is totally polluted. The sovereign mind employs various means to deliver his offspring from this deplorable servitude, especially the ministry of divine messengers, whom he sends to enlighten, to admonish, and to reform the human race. In the mean time, the imperious demiurge exerts his power in opposition to the merciful purpose of the Supreme Being, resists the influence of those solemn invitations, by which he exhorts mankind to return to him, and labours to efface the knowledge of God in the minds of intelligent beings. In this conduct, such souls, as, throwing off the yoke of the creators and rulers of this world, rise to their supreme parent, and subdue the turbulent and sinful motions, which corrupt matter excites within them, shall, at the dissolution of their mortal bodies, ascend directly to the pleroma. Those, on the contrary, who remain in the bondage of servile superstition, and corrupt matter, shall, at the end of this life, pass into new bodies, until they awake from their sinful lethargy. In the end, however, the supreme God shall come forth victorious, triumph over all opposition, and, having delivered from their servitude the greatest part of those souls that are imprisoned in mortal bodies, shall dissolve the frame of this visible world, and involve it in a general ruin. After this solemn period, primitive tranquillity shall be restored in the universe, and God shall reign with happy spirits, in undisturbed felicity, through the everlasting ages." Mosheim's Eccl. Hist. vol. 1. &c. 8vo.

After all it is not easy to form any very consistent and intelligible notion of the sentiments, either of the Oriental philosophers, or of the ancient Gnostics, who sprung from them. The Gnostics, according to Brucker's account of them, conceived the emanations from Deity, which we have already mentioned, to be divided into two classes; the one comprehending all those substantial powers, which are contained within the divine essence, and which complete the infinite plenitude of the divine nature; the other existing externally with respect to the divine essence, and including all finite and imperfect natures within the divine essence. They, with wonderful ingenuity, imagined a long series of emanative principles, to which they ascribed a real and substantial existence, connected with the first substance as a branch with its root, or a solar ray with the sun. When they begun to unfold the mysteries of this system in the Greek language, these substantial powers, which they conceived to be comprehended within the πληρωμα, divine plenitude, they called αιωνες, æons; and they discoursed about them with as much confidence and familiarity, as if they had been objects of sight. The notions which they entertained of these æons, like the Platonic notion of ideas, was that of beings which existed distinctly and substantially. Within this series they included the Demiurgus, or maker of the world, whom they supposed to have been an æon, so far removed from the first source of being as to be allied to matter, and capable of acting upon it. Having conceived both the spiritual and material world to have flowed from the same fountain, their system required substantial virtues, or powers, of two kinds, active and passive; hence, in their figurative and emblematical language, they speak of male and female æons.

ORIFICE, ORIFICIUM, the mouth or aperture of a tube, pipe, or other cavity.

There are some operations in chemistry, where the orifices of the vessels must be sealed hermetically.

ORIFICE, in *Anatomy*, is particularly applied to the mouths of the several ducts, vessels, and other cavities; as of the bladder, uterus, stomach, &c.

The upper orifice of the stomach is the part where hunger is felt; the lower orifice is called the *pylorus*.

ORIFICE is also used by extension, for the aperture of a wound or ulcer.

ORIGANUM, in *Botany*, an ancient name, borrowed from the Greeks, and formed of ορος, *a mountain*, and γανος, *joy*, in allusion to its place of growth and agreeable fragrance. Dioscorides has several species of his οριγανος, which are easily referrible to some one or other of ours. Linn. Gen. 297. Schreb. 393. Willd. Sp. Pl. v. 3. 132. Mart. Mill. Dict. v. 3. Sm. Fl. Brit 638. Prodr. Fl. Græc. Sibth. v. 1. 416 Ait. Hort. Kew. ed. 2. v. 3. 411. Juss. 115. Tourn. t. 94. Lamarck Illustr. t. 511. Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juss.

Gen. Ch. *Cal.* a spiked involucrum, composed of ovate, imbricated, coloured leaves; perianth unequal, various. *Cor.* of one petal, ringent; tube cylindrical, compressed; upper lip erect, flat, obtuse, notched; lower in three deep nearly equal segments. *Stam.* Filaments four, thread-shaped, as long as the corolla, two of them longest; anthers simple. *Pist.* Germen superior, four-cleft; style thread-shaped, directed towards the upper lip of the corolla; stigma very slightly divided. *Peric.* none, except the closed calyx, containing the seeds in its lower part. *Seeds* four, ovate.

Ess. Ch. Cone quadrangular, spiked, with one leaf to each calyx. Upper lip of the corolla erect, flat; lower in three deep equal segments.

Obs. The involucrum affords the essential character of this genus. The perianth is, in some species, nearly equal,

of

of five teeth; in others two-lipped, the upper lip large and undivided, the lower ſcarcely diſcernible; in a few ſpecies it is two-lipped.

1. O. *ægyptiacum.* Egyptian Marjoram. Linn. Sp. Pl. 822. (Zatarhendi; Alpin. Egypt. ed. 1. t. 40. ed. 2. t. 95.) —Leaves orbicular, fleſhy, downy. Spikes leafleſs.—A native of Egypt. Not rare in greenhouſes, where it flowers in the ſummer. The *ſtem* is buſhy and woody. *Leaves* numerous, oppoſite, ſtalked, orbicular, entire, obtuſe, about half an inch wide, tapering at the baſe, fleſhy, downy on both ſides, highly fragrant when rubbed, with a nutmeg-like ſcent. *Flowers* ſmall, whitiſh, in denſe, cluſtered, terminal, hairy, obtuſe ſpikes.

2. O. *Dictamnus.* Dittany of Crete. Linn. Sp. Pl. 823. Curt. Mag. t. 298.—Lower leaves woolly. Spikes drooping. —Native of rocks in Crete, nor did the late profeſſor Sibthorp find it in any other place in the Levant. The *ſtem* is ſhrubby. *Leaves* ovate, clothed with looſe wool, aromatic, but not ſo ſweet-ſcented as the former. *Involucrum* lax, purpliſh, ſmooth, dotted with reſinous points. This, the celebrated δικταμνος of the Greeks, was reported to cauſe the arrows to drop out of the wounded goats, as ſoon as they taſted it; ſee Ælian. It has been cultivated in our greenhouſes as long, perhaps, as any other exotic.

3. O. *Tournefortii.* Dittany of Amorgos. Sibth. in Ait. Hort. ed. 1. v. 2. 311. ed. 2. v. 3. 412. Willd. n. 4. Andr. Repoſ. t. 537. (O. Dictamni cretici facie, folio craſſo, nunc villoſo, nunc glabro; Tourn. Cor. 13. Voy. v. 1. 91, t. 91.)—Leaves ſomewhat fringed. Spikes oblong, erect. Corolla with a ſpur.—Native of rocks in the iſland of Amorgos, near the convent of the virgin. This has the habit of the laſt, but the *leaves* are more rigid, and nearly ſmooth, except at their edges; *ſpikes* longer, erect, and of very numerous *flowers*, whoſe *corolla* has a ſhort ſpur, an eſſential mark of diſtinction between this ſpecies, which therefore ought to have been called *calcaratum*, and the laſt.

4. O. *ſipyleum.* Dittany of Mount Sipylus. Linn. Sp. Pl. 823. (O. montis Sipyli; Herm. Lugd. Bat. t. 463.) —Leaves ovate, acute, all ſmooth. Spikes drooping.—Native of mount Sipylus, in Phrygia, and mount Delphi in the Negropont, as well as by the road ſide between Smyrna and Burſa. *Sibth.* An elegant perennial herbaceous ſpecies, kept occaſionally in our greenhouſes, of a ſlender habit, with rather glaucous naked *leaves*, and ſhort, ſolitary, lax, drooping, purple *ſpikes*.

5. O. *creticum.* Cretan Marjoram. Linn. Sp. Pl. 823. (O. Onites; Tourn. Inſt. 199. Genuina græcorum hyſſopus; Lob. Ic. 494. f. 2.)—Leaves ovate, nearly entire, with roughiſh veins. Spikes cluſtered, oblong, erect. Leaves of the involucrum ovate, acute, membranous, ſmooth.—Native of the ſouth of Europe; a hardy perennial with us, flowering in July and Auguſt. This has much the habit of the Common Marjoram of Britain, hereafter deſcribed, but the long ſlender *ſpikes* diſtinguiſh it, both from that and the following. *O. creticum* is the Wild *Origanum*, or Marjoram, of Dioſcorides and of the modern Greeks.

6. O. *ſmyrnæum.* Smyrna Marjoram. Linn. Sp. Pl. 823. Sm. Fl. Græc. Sibth. t. 571, unpubliſhed. (O. glanduloſum; Desfont. Atlant. v. 2. 27. Willd. n. 11.)—Leaves ovate, roughiſh, nearly entire. Spikes nearly globoſe, obtuſe, hairy, collected into a corymboſe head.—Gathered by Wheeler and Sibthorp about Smyrna. The latter found it alſo on heaths about Conſtantinople. The Turks call it *Sater*, the modern Greeks ζίγανι, or Marjoram. This appears, by Vaillant's herbarium, to be the *O. heracleoticum, cunila gallinacea Plinii, floribus candidis;* Tourn. Inſt. 199, which is cited by Linnæus from Bauhin, under *O. heracleoticum.* The excellent deſcription in Desfontaines, leaves no doubt as to his ſynonym. We thus get rid of one ſpecies of Willdenow. The round, hairy *ſpikes*, collected into a broad-topped corymboſe tuft, mark the plant before us.

7. O. *heracleoticum.* Winter Sweet Marjoram. Linn. Sp. Pl. 823. Lob. Ic. 492. Matth. Valgr. v. 2. 60. Ger. em. 666.—Leaves ovate. Spikes elongated, ſtalked, cluſtered. Involucrum the length of the calyx.—Native of the ſouth of Europe. Dr. Sibthorp found it frequent on the dry hills of Greece. It has long been a hardy perennial in gardens, flowering from June to November, and is nearly related to the next, as well as to *O. creticum.*

8. O. *vulgare.* Common Marjoram. Linn. Sp. Pl. 824. Curt. Lond. faſc. 5. t. 39. Engl. Bot. t. 1143. Woodv. Med. Bot. t. 164. Camer. Epit. 469. (O. anglicum; Ger. em. 666.)—Leaves ovate. Spikes roundiſh, panicled, cluſtered, ſmooth. Involucrum ovate, longer than the calyx. —Native of Europe, in dry hilly places. With us it chiefly occurs in thickets, on chalk or limeſtone, flowering in July and Auguſt. The whole herb has a hot aromatic taſte and ſmell, like thyme. The *root* is perennial, ſomewhat creeping. *Stems* hairy, purple. *Leaves* entire, dark green, dotted, rather hairy. *Spikes* numerous, cluſtered, denſe, ſhort, and ovate; their *involucrum* dark purple; *corolla* roſe-coloured. Bees are fond of the flowers.

9. O. *onites.* Pot Marjoram. Linn. Sp. Pl 824. (O. lignoſum ſyracuſanum perenne, umbellâ ampliſſimâ brevi, lato & nervoſo folio nigricante; Bocc. Muſ. 43. t. 38. Majorana cretica, origani folio, villoſa, ſatureiæ odore, corymbis majoribus albis; Tourn. Cor. 13, by his own herbarium.)—Leaves heart-ſhaped, downy. Spikes oblong, obtuſe, hairy, cluſtered.—Native of Sicily, the ſouth part of Greece, and the neighbouring iſlands of the Archipelago. A pale hairy plant, with white *flowers*, in ſhort blunt crowded ſpikes, whoſe involucral leaves are hairy, and ſtrongly fringed. This plant appears in Hudſon's Fl. Anglica, but erroneouſly, what Dillenius meant appearing to be rather a variety of *O. vulgare.*

10. O. *Majorana.* Sweet Knotted Marjoram. Linn. Sp. Pl. 825. Zorn Ic. t. 41. (Amaracus vulgatior; Lob. Ic. 498.)—Leaves ſtalked, obovate, finely downy, obtuſe. Spikes roundiſh, compact, downy, cluſtered.—Native of Portugal, long cultivated in gardens, where it is either biennial or perennial, always requiring a little ſhelter. Its ſoft downy habit, and ſweet aromatic ſcent, nearly approach *O. ægyptiacum.* The *corolla* is white. Willdenow's *O. majoranoides* ſeems to us a variety; and *O. ſyriacum*, Linn. Sp. Pl. 824, of which there is no ſpecimen in the Linnæan or Bankſian herbarium, appears by Lobel's Ic. 499, to be probably the ſame ſpecies as that of which we are ſpeaking.

11. O. *Maru.* Lavender Marjoram. Linn. Sp. Pl. 825. Sm. Fl. Græc. Sibth. t. 573, unpubliſhed. (Maru creticum; Alpin. Exot. t. 288. Majorana cretica rotundifolia, lavandulæ odore, capitulis minoribus incanis, flore purpuraſcente; Tourn. Cor. 13, from his own herbarium.)—Leaves ovate, ſeſſile, downy. Spikes roundiſh, cluſtered, downy, ſomewhat lax.—Native of mountains in Crete. A ſlender elegant ſpecies, unknown in our gardens. The *leaves* are ſmall, hoary, as are the *ſpikes*. *Corolla* purpliſh red.

We know nothing of *O. ciliatum*, Willd. n. 5, nor of *benghalenſe*, n. 6. The former is a native of Guinea; the latter of Bengal; ſee Burm. Ind. t. 38. f. 3. which figure by no means favours the idea of its belonging to the genus in queſtion.

ORIGANUM, in *Gardening*, affords plants of the herbaceous, annual, and under-ſhrubby perennial kinds, of which

the ſpecies cultivated are, the common marjoram (O. vulgare); the pot marjoram (O. onites); the ſweet or knotted marjoram (O. majorana); the winter ſweet marjoram (O. heracleoticum); the Egyptian marjoram (O. Egyptiacum); and the dittany of Crete or Candia (O. dictamnus).

Of the firſt there are varieties with white flowers, and light-green ſtalks; with purple flowers, and with variegated leaves; which is ſometimes cultivated in gardens, under the title of *pot marjoram*, uſed in ſoups.

The fourth ſort is at preſent commonly known by the name of *winter ſweet marjoram*, but was formerly called *pot marjoram*, being chiefly uſed for noſegays, as coming ſooner to flower than ſweet marjoram.

And there is a variety of it with variegated leaves.

Method of Culture.—The firſt four ſorts may be readily increaſed by ſlips, cuttings, and parting the roots, and in the firſt and third ſorts alſo by ſeeds.

The ſeed ſhould be procured freſh from the ſeed-ſhops, and be ſown in the early ſpring months, as March or the following month, on a bed or border of good light mould, raking it in lightly. When the plants are up, and have attained a few inches in growth, they ſhould be planted out during moiſt weather, in a warm dry ſituation, in rows ten or twelve inches diſtant, to remain, water being given occaſionally till they become perfectly rooted. When the plants are deſigned for the borders or clumps, the ſeeds may be ſown in patches where the plants are to remain.

The roots of the ſtrongeſt plants may be parted, ſo as to have ſome root-fibres to each in the early autumn or ſpring ſeaſon, and be planted out in rows in the ſame manner as thoſe raiſed from ſeed; having the ſame management afterwards till freſh rooted. The ſlips or cuttings of the branches ſhould be taken off in the ſummer, and immediately planted out where the plants are to remain.

All the ſorts ſhould be afterwards kept perfectly clean from weeds during the ſummer ſeaſon, and in the autumn have the decayed ſtalks cleared away, looſening the mould about the plants; and when in beds, digging the alleys and throwing a little of the earth over the beds.

Where neceſſary the plants may be removed into the pleaſure ground, with ſmall balls of earth about their roots, either in the autumn or early ſpring.

The other tender kinds may be increaſed by planting ſlips or cuttings of the young ſhoots, in the ſpring and ſummer months; in the former ſeaſon in pots of light earth, plunging them in a mild hot-bed, but in the latter either in pots or warm ſhady borders; water being immediately given, and occaſionally repeated in ſmall proportions, being covered down by hand glaſſes in the latter caſe, to expedite their rooting; being removed, when the plants begin to ſhoot at the top. In the autumn the plants may be removed into ſeparate ſmall pots, and afterwards treated as the more hardy plants of the green-houſe kind.

The three firſt ſorts are uſeful as culinary plants, as well as ornamental in the borders of the pleaſure ground; and the other kinds afford variety in the green-houſe collections.

ORIGANUM, in the *Materia Medica*. See MARJORAM.

ORIGEN, in *Biography*, one of the moſt celebrated fathers of the church, who flouriſhed in the third century, was born in Alexandria in the year 184 or 185, and was ſurnamed Adamantius, either on account of his indefatigable application to ſtudy, or of the incredible firmneſs with which he endured the perſecutions to which his profeſſion of Chriſtianity expoſed him. By Porphyry he is ſuppoſed to have been born of heathen parents, and educated in their religious principles; but Euſebius, who wrote his life, has ſhewn moſt ſatisfactorily that his parents were Chriſtians, and that they took the greateſt poſſible care of his education. In his childhood he excited the greateſt expectations from his quick improvement in ſeveral parts of knowledge, eſpecially from his exact and profound acquaintance with the holy ſcriptures. He is ſaid to have felt difficulties in the courſe of his reading which his father Leonides was ſcarcely able to ſolve, and he would reprove the youth for aſpiring to a knowledge of things that ſeemed to be above his age; at the ſame time parental attachment led him to believe that his ſon was intended for great things, and he even hoped that he was honoured with the indwelling of the divine ſpirit. When Origen was of a proper age, he became a catechumen in the Chriſtian ſchool of Alexandria, under Clement, by whom he was introduced to an acquaintance with the firſt principles of philoſophy, and impreſſed with a perſuaſion of its utility as preparatory to the ſtudy of Chriſtian truth. After this he attended the philoſophical ſchool of the celebrated Ammonius Saccas, the founder of the Eclectic philoſophy, which was frequented by Pagans and Chriſtians: here he made a great proficiency in the ſtudy of philoſophy, and became intimately acquainted with the writings of the Greek philoſophers; at the ſame time, by his talents and unwearied induſtry, he made himſelf maſter of all the learning of the age. In the year 202, when the perſecutions of the Chriſtians broke out under the emperor Severus, Origen loſt his father, who was firſt thrown into priſon, and ſoon afterwards ſuffered martyrdom. On this occaſion, the love which Origen bore for his father, and for the truth, on account of which he was doomed to ſuffer, excited in him ſo earneſt a deſire to die in the ſame cauſe, and at the ſame moment, that his mother found it neceſſary to hide his clothes to prevent him from going abroad, and throwing himſelf into the way of his perſecutors. Being reſtrained from ſealing the truth with his blood, he wrote a letter to his father, in which he exhorted him to conſtancy, and not to be moved from his ſtedfaſtneſs by compaſſion for his wife and ſeven children. The martyrdom of Leonides being followed by the confiſcation of his property, his wife and children had, at firſt, nothing to rely on for ſupport but the bounty of a rich and honourable lady of Alexandria, till Origen, though now but ſeventeen years of age, was enabled to furniſh them with the means of ſubſiſtence by teaching grammar. In this undertaking he met with great ſucceſs, and his ſchool was crowded with young men, both of Chriſtian and Pagan families. At this time the terror of perſecution had cauſed ſo many to abſcond or flee from the city of Alexandria, that there was no one in the public ſchool to teach the principles of the Chriſtian religion, and many heathens came to Origen, deſiring to be taught by him. The firſt of theſe was Plutarch, who obtained the honour of martyrdom. The ſecond was Heraclius, Plutarch's brother, who became biſhop of Alexandria after the death of Demetrius. Origen was not more than eighteen years of age when he was ſelected to preſide over the catechetical ſchools by appointment of Demetrius: in which important office he gained univerſal eſteem by his frequent viſits, and the other kind offices that he performed, to the confeſſors in priſon, whether ſtrangers or friends. No leſs than ſeven of his ſcholars ſuffered martyrdom, one of whom was a woman. At this time there was no ſtated ſalary for the preſident of the ſchool at Alexandria, and Origen was ſo unwilling to receive a gratuity from thoſe whom he inſtructed in the rudiments of the Chriſtian religion, that he preferred ſelling the books which he had collected with great care, agreeing with the purchaſer for four oboli, equal to five pence, to be paid him daily. It was while he was very young, ſcarcely more than twenty years of

age, that he was guilty of that raſh and unjuſtifiable action, which he intended, as well to preſerve him from temptation, as to fulfil upon himſelf, in a literal ſenſe, the ſaying of Chriſt, when he ſpeaks of thoſe "who make themſelves eunuchs for the kingdom of heaven." He was afterwards ſatisfied of his error, and publicly confuted in his writings the literal interpretation of that text, in ſuch a manner, as to ſhew that he condemned himſelf.

About the year 213 he went to Rome, having a deſire to ſee the moſt ancient church of the Romans. Having made a ſhort ſtay there, he returned to Alexandria, and applied himſelf with great diligence to the ordinary work of teaching the principles of religion. His reputation was now ſo great, and the number of his diſciples increaſed ſo much, that he found it neceſſary to have an aſſiſtant, and ſelected for this purpoſe Heraclius, who became biſhop of Alexandria after the death of Demetrius. About this time he made himſelf acquainted with the Hebrew language, and compoſed his "HEXAPLA;" which ſee. This work induced numbers of learned perſons to reſort to Alexandria, for the ſake of improving by his converſation and inſtructions, among whom was Ambroſe, a wealthy man, who encouraged him to write commentaries upon the ſcriptures, by furniſhing him with what books he required, and by being at the expence of maintaining ſeven or more amanuenſes to write down what he dictated, and as many young women or others, who excelled in the art of writing, to copy his works. After this he went into Arabia, at the invitation of a prince of that country, to inſtruct him in the principles of Chriſtianity. During the perſecutions of the emperor Caracalla he withdrew into Paleſtine, where, at the deſire of the biſhops of the country, he publicly explained the ſcriptures to the people in the churches, and preached in their preſence, though he was only a layman. On his return to Alexandria, he reſumed his office in the ſchool, and alſo his biblical ſtudies. From theſe he was again called by Mammea, mother of the emperor Alexander, who ſent for him to come to her at Antioch, that ſhe might enjoy the benefit of his converſation on religious ſubjects. On his return he remained at Alexandria till the year 228, when Demetrius ſent him on buſineſs to Achaia, and in the courſe of his journey he was ordained preſbyter at Cæſarea, a circumſtance that gave great offence to Demetrius, who had long been jealous of his increaſed and increaſing reputation, and from this time his conduct towards Origen was marked by the moſt determined and violent enmity. He procured a decree to be paſſed, that not only prohibited Origen from teaching any more in the city, but pronounced a ſentence of baniſhment upon him; and he afterwards prevailed on a ſecond council of Egyptian biſhops to depoſe him from the office of preſbyter. The biſhop of Rome and other prelates concurred in the ſentence; but the biſhops of Paleſtine, Arabia, Phœnicia, and Achaia, who were well acquainted with his extraordinary merit, and knew him perſonally, refuſed to join in his condemnation, and continued to entertain the reſpect for him to which he was juſtly entitled. In the mean time Origen had retired to Cæſarea in Paleſtine, where he was well received by the biſhop of that city and the biſhop of Jeruſalem, who determined to ſupport him, and commiſſioned him to deliver interpretations of the ſcriptures, and other religious inſtructions. He opened a ſchool here, in which he taught ſacred and profane learning to a numerous train of diſciples. About the year 240, Origen took a ſecond journey to Athens, where he probably ſtaid ſome length of time, ſince he finiſhed at that place his "Commentary" upon Ezekiel, and began that upon Canticles.

When Origen was about ſixty years of age, he permitted the diſcourſes which he made to the people to be taken down by ſhort-hand writers: of theſe there were more than a thouſand, being accuſtomed to preach daily, with little, or ſcarcely any preparations. About the ſame period he wrote his eight books againſt Celſus, his "Commentaries" upon the minor prophets, and upon the goſpel by St. Matthew. During the Decian perſecution, and in the year 250, he ſuffered much with exemplary and invincible fortitude, on account of his great zeal in the Chriſtian cauſe. Though far advanced in life, he was impriſoned and chained down to his place, and in ſuch a ſituation as to excite the moſt excruciating pains. But neither his ſufferings nor the threats of his perſecutors, could ſhake his conſtancy, or induce him to behave in a manner in the leaſt unworthy of his Chriſtian profeſſion. From his own letters it appears that he ſurvived this perſecution, and afforded arguments for conſolation to others who might be placed in the ſame or ſimilar circumſtances. He died, and was buried at Tyre, in the time of Gallus, in the 70th year of his age. His works were very numerous; but though ſeveral catalogues of them were compoſed, none of them are remaining. It was ſaid he had written 6000 volumes, to which Dr. Lardner ſeems to give credit; but, according to Jerome, they did not amount to more than a third part of that number. A large part of his works is entirely loſt, and of thoſe that remain, the greateſt portion conſiſts of Latin tranſlations, made by Jerome and Rufinus, chiefly the latter; nevertheleſs, ſays Dr. Lardner, "we ſtill have, in the original Greek, Origen's treatiſe of Prayer: his Exhortation to Martyrdom, addreſſed to Ambroſe and Protoctetus, written in the perſecution under Maximin: his Apology for the Chriſtian Religion, in eight books, againſt Celſus the Epicurean, compoſed, as ſome think, in the year 246, or, according to others, not before 249, an excellent performance, greatly eſteemed, not only by Euſebius and Jerome, but likewiſe by many judicious men of later times." Of the high eſtimation in which this extraordinary man was held, ſome notice muſt be taken. Jerome, in his work "De Viris Illuſtribus," calls him a man of immortal wit, and aſcribes to him a deep knowledge of logic, geometry, arithmetic, muſic, grammar, and rhetoric, and of the opinions of all ſects of philoſophers; ſo that there was a great reſort of perſons to him for the ſake of inſtruction: he alſo ſtyles him the greateſt doctor of the churches ſince the Apoſtles; in another place, he ſays, he would willingly undergo all the hatred Origen had ever met with, if he had but his knowledge of the ſcriptures: again, he adds, that Origen was a great man from his childhood, and the true ſon of a martyr; that he trampled the world under foot, vanquiſhing both the love of pleaſure and of riches, and that he had the ſcriptures by heart, and laboured day and night in ſtudying and explaining them. Sulpitius Severus ſays of Origen, "he wonders how one and the ſame man could be ſo different from himſelf: that where he is right, he had not had an equal ſince the Apoſtles." After reciting theſe and other teſtimonies to the character and talents of Origen, Dr. Lardner adds from his own reading, that "he had a capacious mind, and a large compaſs of knowledge; and throughout his whole life was a man of unwearied application in ſtudying and compoſing works of various ſorts, ſome of them extremely tedious and laborious, and in teaching by word of mouth, in the way of catechetical inſtruction, public diſcourſes to the people, and conference. He had the happineſs of uniting different accompliſhments, being at once the greateſt preacher, and the moſt learned and voluminous writer of the age: nor is it eaſy to ſay which is moſt admirable, his learning or his

virtue. In a word, it muſt be owned that Origen, though not perfect nor infallible, was a bright light in the church of Chriſt, and one of thoſe rare perſonages that have done honour to human nature." The ſame author enters at large into the nature and moral tendency of the works of Origen, concerning which we refer our readers to the third volume of his "Credibility;" it will be ſufficient for us briefly to notice ſome of the principal, which may be divided into two claſſes: the former conſiſting of works upon the ſacred ſcriptures; the latter of ſeparate treatiſes upon different ſubjects. We have already referred to the HEXAPLA, and ſhall, in the alphabetical order, give an account of the TETRAPLA, which was compiled for the uſe of ſuch ſcholars as could not procure the Hexapla, and which conſiſted of the Greek verſions of Aquila, Symmachus, the ſeventy Interpreters, and Theodotion. Theſe works afforded the hint for our Polyglott bibles. The other works of Origen upon the ſcriptures, conſiſted of Commentaries upon the books of the Old and New Teſtament, Scholia, and Homilies. In his Commentaries, the greater part of which is now loſt, he appears to have given full ſcope to his learning and imagination, in illuſtrating what was the hiſtorical or literal; the myſtical and moral ſenſe of the ſacred writings. Of his "Scholia," which were probably ſhort notes explanatory of difficult paſſages, none are now remaining; and of his "Homilies," we have only the tranſlations made by Jerome and Rufinus. In the works of Cave and Dupin will be found an account of theſe remains, and of the collections in which they are ſeparately preſerved. With regard to the ſeparate pieces of Origen on different and miſcellaneous ſubjects, we have, beſides thoſe to which we have already referred in this article, "A Letter to Africanus concerning the Hiſtory of Suſannah;" another "Letter to Gregory Thaumaturgus;" fragments of other "Letters," and "Philocalia," containing extracts out of Origen's works by Gregory Nazianzen and Baſil the Great; theſe are in Greek. The Latin tranſlations of Origen's pieces have been accuſed, and probably with great juſtice, with a want of fidelity: this is proved by the introduction into them of polemical terms which were not in uſe till after the council of Nice; and it has been ſuppoſed by ſome learned perſons that the pieces ſtill extant in Greek have been interpolated, or otherwiſe altered, to make Origen ſpeak more agreeably to modern orthodoxy upon original ſin, and other controverted points, than he really wrote or thought. The works of Origen, which are communicated to us only through the medium of Latin verſions, were collected by Merlin, and afterwards by Eraſmus, and publiſhed at Paris in 1512, and at Baſil in 1536, in two volumes folio. In 1574, a larger collection, including pieces tranſlated by the editor, was publiſhed at Paris under the care of Gilbert Genebrard, in two volumes, and was reprinted in 1604 and 1619. M. Huet, biſhop of Avranches, publiſhed in 1668 the Greek fragments of Origen's "Homilies," and his "Commentaries" upon the ſcriptures, with a Latin verſion, to which are prefixed copious and learned prolegomena, under the title of "Origeniana," containing an account of the life and writings of this father. In 1623, Michael Ghiſleri publiſhed at Rome Origen's "Commentary on the 28th chapter of the firſt book of Samuel," containing an account of Saul's viſit to the pretended witch at Endor, and fragments of his "Commentaries" on the prophecy of Jeremiah, with eight Homilies, on the ſame book. In 1605, Origen's "Eight Books againſt Celſus" were publiſhed in Greek with a Latin verſion by Gelenius, and the notes of Hæſchelius, and were afterwards given to the public more correctly at Cambridge in 1658 by William Spencer, who improved the tranſlation, and gave additional notes of his own. This edition compriſes the author's "Philocalia ſive de obſcuris Sacræ Scripturæ Locis." A complete edition of all the remains of Origen, in Greek and Latin, was commenced at Paris by Charles de la Rue, a Benedictine monk, in the year 1733: the editor died in 1739, when only three volumes of his work were publiſhed; but it was continued after his death by his nephew, Charles Vincent de la Rue, a member of the ſame religious community, *viz.* St. Maur, who publiſhed the fourth and laſt volume in the year 1759. Cave. Dupin. Lardner, vol. ii. edit. 1788. p. 442—544. Enfield's Hiſt. Phil. vol. ii. See alſo our article ORIGENISTS.

ORIGEN, a Gentile philoſopher, and a contemporary of the foregoing, was the diſciple and friend of Porphyry, and alſo ſtudied philoſophy under Ammonius. This perſon has ſometimes been confounded with the Chriſtian Origen; but he is the ſame whom Plotinus ſucceeded in the philoſophical chair, and of whom mention is made by Longinus, Porphyry, Hierocles, Eunapius, Proclus, and others.

ORIGENIANS, ORIGENISTS, or *Origeniani*, in *Eccleſiaſtical Hiſtory*, a ſect of ancient heretics, who reſembled or even ſurpaſſed the abominations of the Gnoſtics.

St. Epiphanius ſpeaks of them as ſubſiſting in his time, but in very ſmall number. He charges them with licentious principles, as well as ſhameful practices. He ſeems to fix their riſe about the time of the great Origen; but does not ſay they took their name from him. On the contrary, he diſtinguiſhes them from the Origeniſts, whom he derives from Origen Adamantius; adding, indeed, that they firſt took their name from one Origen; by which he intimates, that it was not the great Origen. And St. Auguſtine ſays expreſsly it was another. As to their doctrine, all that modeſty will allow to be ſaid is, that they rejected marriage; that they received and read divers ſcriptures of the Old and New Teſtament; that they uſed ſeveral apocryphal books, as the acts of St. Andrew, &c. and that, to excuſe their open crimes, they accuſed the Catholics of doing the ſame in private.

It is diſputed by learned moderns, whom theſe people followed, and from whom they were named. Baſnage thinks it likely that there was ſome other Origen, unknown to us, who was the author of this ſect. Baronius thought there was but one Origen about this time; and that theſe Origeniſts had their name from him: of this opinion alſo are Huet and Pagi. Dr. Lardner profeſſes himſelf much inclined to the ſame opinion; and to him it ſeems that the whole ſtory of the impure Origeniſts is unfounded. His reaſons are, that the ſtory depends entirely upon the authority of Epiphanius, and that the account itſelf is improbable in itſelf; becauſe it is hardly credible that men ſhould at any time avow principles and practices ſo abſurd and ſhameful as thoſe imputed to theſe people. Beſides, they made great pretenſions to ſtrict piety; and, moreover, if Epiphanius had had any certain knowledge or good information concerning theſe people, as a diſtinct ſect, he would have been able to ſay whom they followed; but he owns that he was an abſolute ſtranger as to that point. Hence Lardner concludes, that this ſect of impure Origeniſts is a fictitious and imaginary ſect; owing its ſuppoſed exiſtence to the calumnies of ſome bitter enemy of Origen and his admirers; the credulity of Epiphanius, and his too great facility in receiving the ſtories brought to him; together with his favourable ſentiments of the virtue of the great Origen; for, being perſuaded that Origen was a good man, when ſome angry, not to ſay wicked, people brought him the relations to which he refers, he concluded there was ſome ſect called Origeniſts, whoſe riſe and original he could not account for; and therefore he makes a diſtinct hereſy of them. As for the time in which theſe

people lived, it is ſufficient to ſay, that they were in being in the time of Epiphanius, and probably had their beginning when ſome perſons were diſtinguiſhed by the name of Origeniſts. Lardner's Works, vol. iii.

ORIGENISTS, followers of the opinions of Origen, a preſbyter of Alexandria, who, in the third century, maintained that Chriſt is only the Son of God by adoption; that the human ſoul had a pre-exiſtent ſtate, and had ſinned in heaven before the body was created; that the torments of the damned ſhall not be eternal, but that all intelligent beings ſhall be reſtored to order and happineſs, and that the devils themſelves ſhall be relieved at laſt.

Origen, as Moſheim repreſents him, was a man of vaſt and uncommon abilities, and the greateſt luminary of the Chriſtian world that the age in which he lived exhibited to view. Had the juſtice of his judgment been equal to the immenſity of his genius, the fervour of his piety, his indefatigable patience, his extenſive erudition, and his other eminent and ſuperior talents, all encomiums muſt have fallen ſhort of his merit. Yet ſuch as he was, his virtues and his labours deſerve the admiration of all ages, and his name will be tranſmitted with honour through the annals of time, as long as learning and genius ſhall be eſteemed among men. Dr. Lardner has ſummed up Origen's character in a paſſage, for which ſee ORIGEN. However, Origen, notwithſtanding his diſtinguiſhed abilities, was miſled by his imagination, and by that taſte for oriental philoſophy which prevailed in his time. Enchanted by the charms of this philoſophy, (ſee ORIENTAL *Philoſophy*), he ſet it up as the teſt of all religion, and imagined that the reaſons of each doctrine were to be found in that favourite philoſophy, and their nature and extent to be determined by it; nor can it be denied that many of the corruptions of Chriſtianity proceeded from this ſource. Hence ſprung both the ſcholaſtic and myſtic theology, and to the ſentiments that were now adopted, we may aſcribe the riſe of monks and hermits. Origen was alſo miſled by his imagination: for having entertained a notion that it was very difficult, if not impoſſible, to defend every thing in the ſacred writings from the cavils of heretics and infidels, ſo long as they were explained literally, according to the real import of the terms, he maintained that the ſcriptures were to be interpreted in the ſame allegorical manner that the Platoniſts explained the hiſtory of the gods. In conſequence of this pernicious rule of interpretation, he alleged, that the words of ſcripture were, in many places, abſolutely void of ſenſe; and that though in others there were, indeed, certain notions conveyed under the outward terms, according to their literal force and import, yet it was not in theſe that the true meaning of the ſacred writers was to be ſought, but in a myſterious and hidden ſenſe, ariſing from the nature of the things themſelves. This hidden ſenſe he endeavours to inveſtigate throughout his commentaries, neglecting and deſpiſing, for the moſt part, the outward letter. He divided this hidden ſenſe into moral, which diſplays thoſe doctrines that relate to the ſtate of the ſoul and the conduct of life; and myſtical or ſpiritual, which repreſents the nature, the laws, and hiſtory of the ſpiritual or myſtical world. This myſtical world he again ſubdivided into two diſtinct regions, one called the ſuperior, *i. e.* heaven; and the other the inferior, by which he meant the church. And thus he was led to another diviſion of the myſtical ſenſe into an earthly or allegorical ſenſe, adapted to the inferior world; and a celeſtial or anagogical one, adapted to the ſuperior region. Origen found a violent enemy in Demetrius, biſhop of Alexandria; who obliged him, in the year 231, to retire from his charge in Cæſarea: and farther, to ſatisfy his vengeance, he aſſembled two councils at Alexandria, in the firſt of which he condemned him unheard; and deprived him of his office; and in the ſecond had him degraded from the ſacerdotal dignity. In one of theſe councils, eſpecially the latter, Demetrius accuſed him of erroneous ſentiments in religion; for it was about this time that Origen publiſhed his "Book of Principles," which contains many of his peculiar opinions, which were reckoned of dangerous tendency. However, the character and doctrine of Origen were held by many, and eſpecially by the monks, in the higheſt veneration, and cheriſhed in this and the following centuries with a kind of extravagant enthuſiaſm. Hence many commotions were raiſed in the church, which were terminated by the fifth general council, aſſembled at Conſtantinople, by Juſtinian, A.D. 553, in which Origen and his followers were again condemned. The tenets of Origen which gave the greateſt offence were the following: *viz.* 1. That, in the Trinity, the Father is greater than the Son, and the Son than the Holy Ghoſt. 2. The pre-exiſtence of ſouls, which Origen conſidered as ſent into mortal bodies for the puniſhment of ſins committed in a former ſtate of being. 3. That the ſoul of Chriſt was united to the word before the incarnation. 4. That the ſun, moon, and ſtars, &c. were animated and endowed with rational ſouls. 5. That after the reſurrection, all bodies will be of a round figure. 6. That the torments of the damned will have an end; and that, as Chriſt had been crucified in this world to ſave mankind, he is to be crucified in the next to ſave the devils.

St. Epiphanius inſiſts very largely on the errors of this father: but, as he declares himſelf too warmly againſt him, there may be ſomewhat of exaggeration in what he ſays. Nor do St. Jerome, who in the earlier part of his life tranſlated many of Origen's works into Latin, and frequently commended him, calling him the greateſt doctor of the church ſince the times of the Apoſtles, or Theophilus of Alexandria, ſeem to have kept their zeal within the proper bounds in ſpeaking of Origen. When the Nitrian monks, baniſhed from Egypt on account of their attachment to Origen, took refuge at Conſtantinople, and were treated by St. Chryſoſtom, the biſhop of that city, with clemency and benignity, the elegant prelate was accuſed of being an Origeniſt, and condemned to baniſhment by the council of Chalcedon, in the year 403. Origeniſm ſpread itſelf chiefly among the monks of Egypt.

The myſtic theology of Origen ſeems to be adopted by our modern Quakers. On the ſubject of this article conſult Moſheim's Eccl. Hiſt. vol. i. Lardner's Works, vol. ii.

ORIGINAL, a firſt draught, deſign, or autograph, of any thing; ſerving as a model, or exemplar, to be imitated or copied.

Scarcely any of the ancient titles, tenures, &c. are now found in the originals. They are only vidimuſes, or copies collated from the originals.

ORIGINAL *Contract*. See CONTRACT.

ORIGINAL *Conveyances*. See CONVEYANCE.

ORIGINAL *of a Deed*, denotes that part or copy which is executed by the grantor, where the ſeveral parts of an indenture are interchangeably executed by the ſeveral parties; and the reſt are "counterparts;" though of late it is moſt frequent for all the parties to execute every part, which renders them all originals. See DEED.

ORIGININAL *Proceſs*. See PROCESS.

ORIGINAL, or *Original Writ*, is the beginning or foundation of the ſuit. When a perſon has received an injury, he is to ſeek legal redreſs by application or ſuit to the crown, for that particular ſpecific remedy which he is adviſed to purſue. In any action he is to ſue out, or purchaſe by paying

ing the ſtated fees, an *original* or original writ, from the court of chancery, in which all the king's writs are framed.

This is a mandatory letter from the king in parchment, ſealed with his great ſeal, and directed to the ſheriff of the county in which the injury is committed, or ſuppoſed ſo to be, requiring him to command the wrong doer or party accuſed, either to do juſtice to the complainant, or elſe to appear in court, and anſwer the accuſation againſt him. Whatever the ſheriff does in purſuance of this writ, he muſt *return* or certify to the court of common pleas, together with the writ itſelf: which is the foundation of the juriſdiction of that court, being the king's warrant for the judges to proceed to the determination of the cauſe. In ſmall actions, however, below the value of 40*s*. which are brought in the court-baron, or county-court, no royal writ is neceſſary; but the foundation of ſuch ſuits continues to be, as in the times of the Saxons, not by *original writ*, but by *plaint*; that is, by a privats memorial tendered in open court to the judge, wherein the party injured ſets forth his cauſe of action, and the judge is bound of common right to adminiſter juſtice therein, without any ſpecial mandate from the king. Now, indeed, the royal writs are held to be demandable of common right, on paying the uſual fees; for any delay in the granting of them, or ſetting an unuſual or exorbitant price upon them, would be a breach of Magna Carta, c. 29. "nulli vendemus, nulli negabimus, aut differemus juſtitiam vel certum,"

Original writs are either *optional* or *peremptory*; or, in the language of our lawyers, they are either a "præcipe" or a "ſi tē fecerit ſecurum;" which ſee. Both ſpecies of writs are *teſte'd*, or witneſſed, in the king's own name; "witneſs ourſelf at Weſtminſter," or wherever the chancery may be held. (See RETURN and TERMS.) The next ſtep for carrying on the ſuit, after ſuing out the original, is called the *proceſs*; which ſee.

ORIGINAL *Sin*. See SIN.

ORIGINALIA, in the *Exchequer*, are records or tranſcripts ſent to the remembrancer's office out of chancery.

They differ from *recorda*, which contain the judgments and pleadings in ſuit tried before the barons.

ORIGINARY, ORIGINARII, among the Romans, an appellation given to ſlaves born in their maſter's houſes, who were otherwiſe called *vernæ*.

ORIHUELA, in *Geography*, called *Auriola* by the Romans, *Orzuella* by the Goths, *Orguella* by the Moors, and *Orihuela* by the Aragoneſe and the Spaniards, is a tolerably large town of Spain, in the province of Valencia, agreeably ſituated at the foot of the mountain of the ſame name, on both banks of the Segura, which runs through it, and which, on the confines of a beautiful country, forms the continuation of the Huerta of Murcia. This town was taken from the Conteſtani by the Carthaginians, from them by the Romans, and from theſe by the Goths; it was conquered by the Moors in 715, and at firſt formed part of the kingdom of Cordova; in 1057 it had its own king, but ſoon afterwards returned to the kings of Cordova; by a freſh revolution it became dependent on the new kingdom of Murcia, eſtabliſhed in 1236; it remained under the Moors for 550 years. It was taken from them in 1264 by James I. king of Aragon, who peopled it with Chriſtians, and in 1537, it received the title of city from Alphonſo V. In 1648, it was depopulated by the plague; and the overflowing of the Segura in 1651, deſtroyed a great part of it. This town is narrow, but as it winds round the foot of the mountain, its extent is conſiderable. It is tolerably well built; the ſtreets are in general airy, ſtraight, and broad, but not paved. The eleven principal ſtreets are handſome, and the broadeſt of them have pavements on each ſide. It has many regular edifices, and houſes of good appearance. It has two bridges over the Segura, ſeven gates, and five ſquares. It has no fountains, ſo that the inhabitants drink the water of the Segura. The population is about 20,000 perſons. In 1564, pope Leo X. eſtabliſhed a biſhop's ſee in this place, which has continued ever ſince, and it has a cathedral chapter. Here are three pariſh churches, nine monaſteries, three nunneries, a hoſpital for the ſick, a foundling hoſpital, and a tribunal for the cognizance of cauſes ariſing in the dioceſe. Beſides a number of officers for the civil and military adminiſtration, it has a garriſon of two ſquadrons of cavalry, or of dragoons. In this city is an univerſity, founded in 1556, for the four learned profeſſions; here are alſo one ſeminary and two colleges, one of which accommodates about 300 young men. A ſmall theatre was erected in this place by a private gentleman in 1791, and from the month of October to the month of April it is much frequented. At Orihuela they manufacture thoſe curious ſnuff-boxes with the roots of the terebinthus, called in Spaniſh "Cornicabra," which are ſo much admired on account of their beautiful ſhades, repreſenting landſcapes, &c. The inhabitants are commended for the ſuavity of their manners, and for the induſtry with which they cultivate the adjacent lands. The country about the town is very beautiful, and forms a ſucceſſion of gardens, producing abundance and variety of fruits, ſuch as oranges and lemons, almonds and pomegranates. The fertility of the ſoil has occaſioned a proverb, "rain or no rain, there is wheat in Orihuela." Here are raiſed ſilk-worms in great number; which furniſh the inhabitants with a new ſource of wealth. N. lat. 38° 7′. W. long. 1° 5′.

ORIHUELA, a town of Spain, in the province of Aragon; 18 miles N.W. of Albarracin.

ORIHVASI, a town of Sweden, in Tavaſtland; 40 miles N. of Tavaſthus.

ORIJAVA, a town of Spain, in the province of Granada; 12 miles N. of Motril.

ORILLAH, a town of Bengal; ſeven miles W. of Ramgur.

ORILLON, in *Fortification*, a ſmall rounding of earth, lined with a wall; raiſed on the ſhoulder of thoſe baſtions that have caſemates, to cover the cannon in the retired flank, and prevent their being diſmounted by the enemy. The method of deſcribing orillons and retired flanks, according to M. Vauban's firſt method, is ſtated under the article *Military* CONSTRUCTION.

ORIMATELA, in *Geography*, a town of Sweden, in the province of Tavaſtland; 45 miles E.S.E. of Tavaſthus.

ORING, a lake of Thibet, 63 miles in circumference. N. lat. 34° 47′. E. long. 97° 29′.

ORINGA, a ſea-port of Japan, in the iſland of Niphon.

ORINIACOORA, a town of Bengal; 15 miles N. of Nuldingah.

ORINOKO. See OROONOKO.

ORINZA, a town of Perſia, in the province of Irak; 41 miles E. of Iſpahan.

ORIO, or ORIA, a town of Spain, in Guipuſcoa, on the ſea-coaſt, at the mouth of a river of the ſame name, ſurrounded by walls; four miles W. of St. Sebaſtian.

ORIOLUS, the Oriole, in *Ornithology*, a genus of birds of the order Picæ, of which the generic character is: a conical, convex, very ſharp pointed and ſtraight bill; the upper mandible is a little longer than the lower, and obſcurely emarginated; the tongue is biſid and ſharp; and the feet are formed for walking. There are 51 ſpecies deſcribed in Gmelin's Linnæus; the birds are generally deſcribed as gregarious,

gregarious, noiſy, numerous, voracious, and great devourers of corn. The greater number of the ſpecies belonging to this genus are natives of the American continent; they are remarkable for the ſtructure of their neſt, which in ſome ſpecies hangs from the branch to which it is attached, and in others it is ſewed or faſtened with peculiar art beneath the ſurface of ſome very large leaf.

Species.

* GALBULA, or Golden Oriole, ſometimes denominated the golden thruſh, is of a pale yellow colour; the lores and limbs are black; the outer tail-feathers on the hind part are yellow; the bill and irides are red; the legs plumbeous; the female is of a duſky browniſh-green; the lateral tail-feathers are of a yellowiſh-white. This is an inhabitant of our own country, and is found alſo in other parts of Europe, in Africa, and in Aſia, is about nine inches and a half long; is migratory; feeds on cherries, berries, and inſects. Its neſt is in the ſhape of a purſe, faſtened to the extreme divarications of the outmoſt twigs of tall trees, and compoſed of fibres of hemp, or ſtraw, mixed with fine dry ſtalks of graſs, lined within with moſs and lichens, upon which are arranged ſtill finer materials, as the ſilken bags of the chryſalides of moths; the egg-bags of ſpiders, feathers, &c. It is uſually obſerved to build generally in high trees, but places its neſt in rather a low part of the tree; the uſual number of eggs is four or five, and their colour a dull white, with numerous dark ſpecks. She ſits three weeks, and will not unfrequently ſuffer herſelf to be taken with the eggs and neſt, and continue to ſit on them in a cage till ſhe dies. The golden oriole is partial to grapes, figs, cherries, and inſects. It has a loud cry, and its fleſh is reckoned wholeſome and pleaſant to the taſte.

There are four other varieties of this ſpecies. 1. The black-headed oriole, deſcribed by Edwards under the title of the black-headed icterus, which differs in having the whole head and throat black, the greater quills black, longitudinally ſtreaked with yellow; the tail and bill reddiſh, and the legs duſky. It is a native of Madras. 2. The mottled oriole, which is yellow variegated with blackiſh ſpots; the head, neck, quill, and tail-feathers blackiſh. It inhabits Madras, and is deſcribed by Edwards under the title of the yellow Indian ſtarling. 3. The Chineſe oriole, whoſe limbs are black with yellow tips; head with a black band. It inhabits divers parts of China and Cochinchina. 4. The Indian oriole, of which the head is marked with a tranſverſe blue band; the tail-feathers are yellow with a blue bar; quill-feathers yellow ſpotted with blue. It inhabits India.

RADIATUS; or Striped-headed Oriole. This ſpecies is tawny; the head, chin, and throat are black dotted with white; the remainder of the bird is orange-coloured. It is not aſcertained to what country this bird belongs; it is the ſize of a black-bird, the body is pale beneath; the legs are yellow; the claws are reddiſh.

PICUS; Climbing Oriole. Tawny; the head, neck, and breaſt are ſpotted with white: the tail is rounded; the bill of a yellowiſh-grey; the legs are blackiſh. It is about ſeven inches long; inhabits among the trees in Guiana, which it climbs like a pie, and picks out inſects from under the bark.

ICTERUS; Icteric Oriole. This is alſo tawny; the head, throat, back, quill and tail-feathers are black; the wings are marked with a white ſpot. The bill is moſtly black with a brown baſe; the irides are yellowiſh; the legs are ſometimes black, and ſometimes lead-coloured, or of a greyiſh-white. It is about nine or ten inches long. It inhabits the warmer parts of America, and the Caribbee iſlands. It is domeſticated for the purpoſe of killing inſects. In its wild ſtate it is very agile and bold. It builds a large cylindrical neſt, ſuſpended to the end of a twig of a tree, with a view, no doubt, to defend its young from the attacks of ſnakes and other animals. Of theſe neſts ſeveral may ſometimes be ſeen near each other, and not far from houſes.

NOVÆ HISPANIÆ; Mexican Oriole. This ſpecies is yellow; the head, chin, quill-feathers, and tail are black. It inhabits New Spain, whence it derives its ſpecific appellation. The bill is long and yellow.

ANNULATUS; Ring-tailed Oriole. This ſpecies is yellow; the head and neck black; the greater wing-coverts and quill-feathers are blackiſh, with a yellowiſh edge; the tail is annulate and blackiſh. It is deſcribed and figured by Seba, is the ſize of a pigeon, and is a native of South America.

PICTUS; Painted Oriole. The front of this ſpecies is yellow; the nape orange-coloured; back yellow; cheeks, rump, and belly blueiſh; the ſhoulders are brown; the quill and tail-feathers are black. It is ſuppoſed to be an inhabitant of America.

BRASILIANUS; Braſilian Oriole. Yellow; breaſt ſpotted; head and back with pale brown ſpots; belly white; tail and wings brown; the latter tipt with whitiſh. It inhabits the ſhrubby places in Jamaica, and is four inches long. The bill is half an inch long; the orbits are yellow; legs brown, claws yellow.

JAPACANI; Japacani Oriole. The colour of this ſpecies is black mixed with a pale brown; beneath it is varied, with white and yellow, with tranſverſe black lines; head and tail blackiſh. Inhabits Braſil, and is eight inches long; the bill is black; the irides golden; the legs are of a dirty-white; claws ſharp and black. It is deſcribed by Ray, Willughby, and Latham.

COSTOTOTL; or New Spain Oriole. Black; beneath and tail variegated with ſaffron and black. It inhabits New Spain, and is about the ſize of a ſtarling. The young are ſaid to be yellow except the tips of the wings, which are black.

GRISEUS; Grey Oriole. This is varied with yellow and black; back, thighs and belly cinereous. It inhabits the woods of New Spain, is the ſize of the laſt; it does not ſing, and the fleſh is good.

PHŒNICŒUS; Red-winged Oriole. This ſpecies is black, but the wing-coverts are tawny; it is the ſize of a ſtarling; the length being from eight to nine inches. It is to be met with in Mexico, the Carolinas, Virginia, and as far as New York. It builds a thick penſile neſt among reeds, or between the forks of trees, three or four feet from the ground, along with other birds, in ſwamps which are rarely acceſſible by man. In Louiſiana theſe birds appear only in winter, and ſometimes in ſuch immenſe flocks, that three or four hundred may be taken at one draught of the net. The nets are ſpread on ſome bare ſmooth path, at the ſide of a wood, with rice ſtrewed to decoy the birds. To ſecure the multitudes that are caught, it is often neceſſary to kill the greater part upon the ſpot. Their trivial or common name is "Maize-thief," which they have acquired from the circumſtance of their pecking a hole in the plant when green, and ſo deſtroying it. They are very bold, and not to be terrified with a gun, for notwithſtanding the ſportſman makes great ſlaughter in a flock, the remainder will take a ſhort flight, and ſettle again in the ſame field. There is a variety found in Africa with the ſhoulders red, edged with yellow.

AMERICANUS; Red-breaſted Oriole, or Mocking-bird of Guiana. Black; chin, throat, breaſt, and upper corner of

of the wings red. It is ſeven inches long, is leſs than a black-bird, and inhabits Guiana and Cayenne. It ſings very pleaſantly, and imitates the notes of other birds. The neſt, which is built of hay, is long, cylindrical, twelve or fifteen inches in circumference, and hangs from the branches of the talleſt trees.

ORYZIVORUS; Rice Oriole. Black; head, neck, and breaſt with a purple ſhade. It inhabits Cayenne, and is nine inches long. The bill is about one inch and a half long, convex, and protuberant at the baſe.

LUDOVICANUS. This is variegated with black and white; the head, neck, belly, and rump are white; the wings and wedged-tail violet, edged with white. It inhabits North America, principally Louiſiana, and is ten inches long. The bill is black, and is about an inch long; the legs are of a lead-colour. There are two varieties of this ſpecies: 1. Blackiſh-brown; neck, breaſt, and wings ſpotted with black; head white, with a black ſpot on the crown. It is found in Hudſon's Bay. 2. Blackiſh-green; head, chin, outer quill-feathers, thighs, and ſtreaks on the breaſt white. This alſo is found in Hudſon's Bay.

CRISTATUS; Creſted Oriole. Creſted; lower part of the back, rump, and vent cheſnut; lateral tail-feathers yellow. This is the largeſt ſpecies yet known, and is a native of Surinam. It is about the ſize of a magpie, and its length is from eighteen to twenty inches. The colour of the male is black, with the lower part of the back, the rump, and vent cheſnut; and the lateral tail-feathers yellow. The head is furniſhed with a narrow recumbent creſt; the bill is of a dull yellow, and the legs black. The female is ſaid to be of an olive colour; the quills are duſky, and the tail yellow, as in the male, with the middle feathers black; the head is creſted, and the eyes in both ſexes are of a bright blue. Nothing is known of the particular hiſtory of this ſpecies, except that it feeds on inſects and fruits, and that it has a ſtrong ſcent, reſembling caſtor. "If," ſays Dr. Shaw, "it reſembles the majority of this genus in its manner of building, it may perhaps be the fabricator of the very large hanging neſt, deſcribed by Grew, in his account of the Muſeum of the Royal Society. It is above three quarters of a yard long, beſides part of it broken off: where broadeſt, near a foot over, and almoſt flat; narrowed from the bottom all the way to the top. It hath two apertures: above, about a foot from the top of the entire neſt, one larger and longer; below, that is, a foot above the bottom, another perfectly round, and three inches over: it conſiſts of the parts of plants ſomewhat looſely woven together." There are two varieties of this ſpecies: 1. One is of an olive-brown; beneath bay; the two middle tail-feathers cheſnut, the lateral ones yellow. It inhabits Cayenne, and is twenty inches long. The bill of this variety is yellow; hind-head with two long pendent briſtly feathers. 2. The body of this on the fore-part is green, the hind-part is cheſnut; the quill and two middle tail-feathers are black, the lateral ones yellow; the bill is red. It inhabits Cayenne, and is fourteen inches long.

HÆMORRHOUS; Red-rumped Oriole. This ſpecies, which is black, and the rump ſcarlet, inhabits Braſil, is eleven inches long, and is reckoned a very elegant ſpecies, though the colours are plain rather than ſplendid or glaring. Specimens have been ſeen, perhaps ſuch as had not attained their full colours, in which the back was of a brown tinge, the rump of a pale red, and the vent yellow. The neſt of this bird reſembles a narrow cucurbit with its alembic, the total length being about eighteen inches, but the interior cavity is only twelve inches; the upper part, by which it is attached, is denſe and ſtrong for about the length of ſix inches. The hæmorrhous prefers building on ſuch trees as overhang a river or lake. There is a variety which is found at Guiana, and which is of a blackiſh-brown colour, with a yellow vent.

PERSICUS; Black and Yellow Oriole. Black; hind-part of the back, ſpot on the wing-coverts, and baſe of the tail-feathers yellow. It is found in South America; forms a pendent neſt, ſimilar to the one juſt deſcribed, on the extreme branches of trees, of which there are ſometimes four hundred together. The eggs are of a dirty white, with ſmall pale brown ſpots. There are two varieties: 1. Black; hind-part of the back, ſpot on the wing-coverts, and outer tail-feathers above yellow at the baſe, all beneath half yellow and black. 2. Purpliſh-black; ſpot on the wings yellow, varied with black. The bill is yellowiſh; irides blue; legs and claws black.

MEXICANUS; Black-crowned Oriole. Blackiſh; beneath and on the head yellow. It inhabits New Spain and Cayenne, and is nearly nineteen inches long. The bill, legs, and claws blackiſh; the neck is yellow; the crown black-brown; tail and wings black.

RUBER; Red Oriole. Vermilion; wings, belly, and tail deepeſt black. The bill and legs black; irides flame colour. This bird is of the ſize of a black-bird, and is found at Antigua, in the iſle of Panay, one of the Philippines.

GUIANENSIS; Guiana Oriole. Blackiſh; edges of the feathers grey; breaſt and neck beneath red. It inhabits Guiana, as its name imports, and is above ſeven inches long. The tail is ſtriate with grey; the legs and claws are brown.

FLAVUS; Antigua Yellow Oriole. Golden; hind-part of the back, wings, and tail are black. The bill and legs are black; the irides are red. It is the ſize of a black-bird, and, according to Sonnerat, is a native of Antigua, in the iſle of Panay; but it is alſo found about the river Plata, in South America.

BALTIMORE; Baltimore Oriole. Blackiſh; beneath and band on the wings tawny. The bill is of a lead-colour; greater wing-coverts black, tipt with white; firſt quill-feathers dirty white, edged with white; two middle tail-feathers black, the reſt black on the lower part, and orange above. In the female, the head and back are olive, edged with browniſh; body beneath and tail-coverts yellow; tail grey, edged with white. This ſpecies is found in many parts of North America, occupying chiefly the more northern parts, advancing even to Montreal in the month of May, and returning ſouthward in winter, which accounts for their appearance in Maryland and Virginia at that time. They make their neſt of a ſoft downy matter, in the ſhape of a purſe, tying it with threads to the extreme forks of twigs of the tulip, plane, and hickory trees. The country people call them *fire-birds;* and indeed, when in high plumage, their motions from branch to branch not unaptly reſemble a flaſh of fire.

SPURIUS; Baſtard Oriole. Black; beneath tawny; wings with a white bar. It inhabits North America, is ſhorter than the Baltimore oriole; builds a penſile neſt, and lays five eggs. The lower part of the back and tail-coverts yellow; quill-feathers grey, edged with white; tail black, wedged. The head and neck of the female are of an olive colour; the chin is black; wing-coverts and tail-feathers grey, edged with white; tail dirty white, edged with yellow.

TEXTOR; Weaver Oriole. This is of a yellow colour; head brown, with a ſhade of golden; quill and tail-feathers blackiſh, edged with orange. It inhabits near Senegal, and

is

is of the ſame ſize as the golden oriole. "It was obſerved," ſays Mr. Latham, "in a cage where theſe birds were kept, that they entwined ſome of the ſtalks of the pimpernel, with which they were fed, in the wires. As this ſeemed to ſhew a diſpoſition of making a neſt, ſome ruſh-ſtalks were put into the cage; on which they preſently made a neſt, large enough to hide one at leaſt: but it was as often deranged as made, the work of one day being ſpoiled the next; ſerving to ſhew that the fabrication of the neſt, in a ſtate of nature, was the work of both male and female, and in all probability is finiſhed by the laſt. They had a ſharp but lively note.

Bonana; Bonana Oriole. This is alſo named the fulvous oriole, on account of its tawny colour. The head and breaſt are cheſnut; back, quill, and tail-feathers are black; the lower part, rump, belly, thighs, vent, and under wing-coverts orange-red; the vent is varied with cheſnut; the greater wing-coverts, quills, and tail are black; the bill is black, with greyiſh baſe; legs are grey. The female differs from her mate in being of a leſs lively colour. It is a native of the Weſt India iſlands, building its neſt in a remarkable manner of fibres and leaves, formed into the fourth part of a globe, and attached to the under-ſide of a banana leaf, in ſuch a manner that the leaf itſelf forms one ſide of the neſt, which, at firſt ſight, appears to be made of horſe-hair, but, on a nearer inſpection, is found to be compoſed of branched fibres, and which are in reality thoſe of the *Tillandria uſneoides*.

Nidipendulus; Hang-neſt Oriole. Frontlet and wreath black; crown, neck, back, and tail reddiſh-brown; breaſt and belly tawny-yellow. The bill is white; wings duſky-brown, mixed with white. This bird builds in woods, making its neſt of the internal fibres of the paraſitic plant, known in the Weſt Indies by the name of "old man's beard." It ſings charmingly, and places its neſt on the external branch of a high tree.

Varius; Cheſnut and Black Oriole. Black; beneath, rump, and leſſer wing-coverts ferruginous. It inhabits Cayenne, and is about ſix inches long.

Xanthornus; Leſſer Bonana Oriole. Pale yellow; chin, quill, and tail-feathers black. It inhabits Jamaica and New Spain, and is ſeven inches long. The wing-coverts are black, the greater part of them is edged with white.

Dominicensis; St. Domingo Oriole. Black; body on the hind-part, wing-coverts, and ſpot on the wings pale yellow. It is found in New Spain, Jamaica, and St. Domingo; is about eight inches long; builds a purſe-ſhaped neſt on the extreme branches of trees, hanging over water.

Jamacaii; Braſilian Oriole. This ſpecies is yellow; the head, throat, ſpot on the ſhoulders, wings, and tail black. It inhabits, as its trivial name imports, Braſil; fixes its neſt to a plantain leaf by means of filaments, and is ten inches long. The bill is black; wing-coverts have a white ſpot in the middle; the legs are brown.

Cayanensis; Yellow-winged Oriole. Black, with a yellow ſpot on the wings. Bill black; tail rounded, a little wedged at the tip.

Leucopterus; White-winged Oriole. Black, with a white ſpot on the wings. The female is of a cinnamon-brown colour, but beneath it is ſomewhat cinereous. It is a native of Cayenne and Surinam, and is about eight inches long.

Icterocephalus; Yellow-headed Oriole. Black; head and neck yellow. The bill is blackiſh; legs and claws brown. It inhabits Cayenne, and is ſeven inches long.

Melancholicus. This is the Schomburger of Edwards. It is grey, dotted with black, with a black band over the eyes. It is the ſize of a lark, which it conſiderably reſembles in colour. The bill and legs of a fleſh colour; the irides are bay; feathers with each a blackiſh ſpot in the middle; quill-feathers and tail blackiſh, edged with tawny brown; cheeks and chin black. It is a native of Mexico. There is a variety, in which the plumage is of a brighter caſt, or more inclining to orange-colour. The head is marked on each ſide by a white eye-ſtripe, bordered above and below with black; the irides are of a reddiſh-orange hue. It is found in Cayenne.

Capensis; Olive Oriole. This is, as its trivial name denotes, of an olive-brown colour, but beneath it is of a pale yellow. The bill, legs, and claws are brown; colour on the crown is inclining to grey, on the chin and throat to orange; the wing-coverts are brown, edged and tipt with olive; quill-feathers brown, edged with olive.

Cæruleus; Blue Oriole. Black, cinereous; head, wings, and tail blue. The bill is tawny. It is found at Madras.

Trifaciatus; Triple-ſtriped Oriole. Blueiſh lead-colour; the head has a triple ſtripe of black, and waved with black on the ſides; the lower part of the back and rump are of a jonquil yellow. This is an Indian bird.

Viridis; Yellow-throated Oriole. Green; eye-brows, cheeks, and chin yellow; ſome of the wing-coverts tipt with white. The bill is corneous; the legs grey. It inhabits Hudſon's Bay, and is about nine inches long.

Ferrugineus; Ruſty Oriole. Black; edge of the wings ruſty; head and neck purpliſh-black; belly of a dirty-aſh. The bill and legs are alſo of a dirty-aſh; the areas of the eyes are black; wings and tail have a greeniſh ſhade.

Fuscus; Brown-headed Oriole. Black, head ruſty-brown; the tail is of a dirty-aſh colour. It is a gregarious bird, and is found in New York.

Niger; Black Oriole. This is totally black; but the female is greeniſh-brown; beneath and on the head inclining to cinereous. It inhabits North America; is about ten inches long; is gregarious, and in brooding time ſings delightfully, feeds on worms and beetles; builds in trees about eight feet from the ground, and lays five eggs, that are duſky, with black ſpots.

Minor; Leſſer Black Oriole. Black; head mixed with a little blue. The head of the female and the neck are of a duſky colour; wings and tail blueiſh.

Olivaceus; Cayenne Olive Oriole. Olive; head, chin, throat, and breaſt brown; wings black. It inhabits Cayenne, and is ſix inches long. The bill and legs are black.

Aoonalaschkensis; Aoonalaſhkan Oriole. This ſpecies is brown; ſpot under the eyes and chin white; the throat and breaſt are of a ruſty-brown; bill and legs brown. It is about eight inches long, and inhabits the iſland Aoonalaſcha.

Caudacutus; Sharp-tail Oriole. Variegated; tail-feathers ſharp-pointed. It inhabits New York; the ſize of a lark.

Sinensis; Kink Oriole. White; head, neck, breaſt, and upper part of the back cinereous; quill-feather ſteel-blue; tail rounded, half of it is white, and half ſteel-blue. It inhabits China, and is about ſix inches and a half long.

Aureus; Tawny-yellow Oriole. This, as its trivial name imports, is of a tawny-yellow colour; frontlet, chin, primary tail-coverts and feathers black at the extremity; the bill is brown. It inhabits India; and is eight inches long.

Viridens; Whiſtling Oriole. Olive, beneath inclining to green; tips of the wings and lower coverts yellow, the upper

upper and greater brown, edged with yellow; tail rounded. The bill is corneous; legs and claws grey.

FURCATUS; Fork-tailed Oriole. Black; back, rump, quill-feathers and forked tail inclining to blue, lower tail-coverts white. Bill yellow; tail long; legs and claws black. It inhabits St. Domingo; and is about ſeven inches long.

CHRYSOCEPHALUS; Gold-headed Oriole. Black; cap, wing, and tail-coverts pale-yellow. The hind-head and thighs golden; bill black; legs and claws black-brown. It inhabits America, and is above eight inches long, but in bulk it is about the ſize of a lark.

ORION, in *Aſtronomy*, one of the brighteſt conſtellations of the ſouthern hemiſphere: and as it occupies a large ſpace there, this circumſtance may probably have given the ancients, and particularly Pindar, occaſion to ſay that Orion was a perſon of a monſtrouſly large ſize, which Manilius expreſſes in theſe words: "magni pars maxima cœli." Nothing was more noted among the ancients than this conſtellation. It is mentioned in ſeveral paſſages of the Bible, *viz.* Job, ix. 9. Ezek. xiii. 10. Amos, v. 5. And both the Septuagint and the Vulgate call it Orion, as well as the Greeks.

The word is formed from the Greek ὁρεῖν, *to make water*; the ancients ſuppoſing, that it raiſed tempeſts at its riſing and ſetting.

The ſtars in the conſtellation Orion, in Ptolemy's catalogue, are thirty-eight; in Tycho's and Hevelius's, ſixty-two; in the Britannic catalogue, ſeventy-eight. See CONSTELLATION.

ORION, in *Mythology*, furniſhes a fable that is the moſt celebrated, and at the ſame time moſt obſcure in antiquity. The birth of Orion exhibits a myſtery equally indecent and difficult to be underſtood. As Jupiter, it is ſaid, Neptune, and Mercury were travelling on the earth, they lodged with Hyrieus, erroneouſly named Byrſeus in Hyginus, and were ſo pleaſed with their entertainment, that they aſked him what was the chief object of his wiſhes, promiſing to beſtow it upon him. Hyrieus anſwered, that having no children, theſe were what he chiefly deſired; and ſoon after Orion was born in the manner related by Hyginus: "Mercurius," ſays he, "de tauro quem Hercules immolaret, corium pertulit. Illi (*i. e.* Jupiter, Neptune, and Mercury) in eum urinam fecerunt, et in terram obruerunt, unde natus eſt Orion;" and hence he obtained the name of Ourion, or Arion. Afterwards, to obliterate the memory of his birth, the firſt letter of his name was changed, and he was called Orion, which Ovid thus expreſſes:

"Perdidit antiquum litera prima ſonum."

Homer, who mentions Orion repeatedly, ſays nothing of the fable of his birth, which probably was not invented in his time. It is certain that Orion ſignalized himſelf by his attachment to the ſcience of aſtronomy, which he had learned from Atlas, who, according to Homer, dwelt in the vicinity of Tanagrus, upon a high mountain, from whence he ſtudied the heavens, or in the iſland of Calypſo, his daughter. Moreover, Orion was paſſionately fond of hunting; and this circumſtance was the foundation of the connection of his hiſtory with that of Diana. Homer is the firſt who attributes Orion's death to the jealouſy of Diana:

"So when Aurora fought Orion's love,
Her joys diſturb'd your bliſsful hours above,
Till in Ortygia, Dian's winged dart
Had pierc'd the hapleſs hunter to the heart."
Pope's Odyſſ. v. 155.

Pauſanias ſays, that Orion's tomb was to be ſeen at Tanagrus in Bœotia; but this was probably merely a cenotaph; ſince he was actually interred in Delos, called Ortygia.

The circumſtance of the three divinities, who are ſaid to have lodged with Orion's father, led our Hebraizers to believe, that this fable was the ſame with, or at leaſt a copy of, the ſtory of Abraham's entertaining the three angels, who came and foretold to him the birth of a ſon, though Sarah his wife was then ſuperannuated. M. le Clerc (Bibl. Univ. t. vi.) had this notion of it, without inſiſting, however, upon the Greek and Hebrew etymologies, which might have given ſome probability to this aſſertion. Blaeu, who took the name of Cœſius (Cœl. Poet. Aſtr. Art. of Orion) inſinuates, that this fame fable had a great reſemblance to the ſtory of Jacob, ſo much the more as the name of Jacob's ſtaff is given to the three brighteſt ſtars in the conſtellation of Orion; and the name of Jacob, which ſignifies "ſtrong againſt the Lord," upon account of the myſterious combat he had with an angel, may have given riſe to it. Beſides, the Arabians call the conſtellation of Orion, "Algebar," or "Algebao," the ſtrong, the giant. The Abbé Fourmont has alſo argued that this ſtory is the ſame with that of the venerable patriarch. In favour of this ſentiment, the authors have to allege, that Orion, being of Tanagrus, a city of Bœotia, the country where Cadmus ſettled, and having there introduced the religion of the Phœnicians, the hiſtory of Abraham, ſo celebrated in all the Eaſt, might have been known there.

ORION'S *River*, in *Aſtronomy*, a conſtellation, called alſo *Eridanus*; which ſee.

ORIPAA, in *Geography*, a town of Sweden, in the government of Abo; 27 miles N.N.E. of Abo.

ORIS COLUMNA. See COLUMNA.

ORIS *Diſtortor*. See DISTORTOR.

ORIS *Speculum*. See SPECULUM.

ORISICCHIO, in *Biography*, an eminent compoſer for the church, at Rome, in 1770. He then ranked ſo high for the elegance, as well as ſcience, of his eccleſiaſtical compoſitions, in Pergoleſi's ſtyle, that upon any feſtival, wherever he was maeſtro di cappella, and had compoſed a maſs, there was ſure to be a great crowd.

ORISSA, in *Geography*, a province of Hindooſtan, bounded on the north by Bahar and Bengal, on the eaſt by the northern circars and the bay of Bengal, on the ſouth by Golconda, and on the weſt by Berar. It was formerly a kingdom, till reduced by Akbar in 1592, and extended from the bay of Bengal to the coaſt of Coromandel; but it is not now ſo extenſive. Under Aurungzebe, it yielded a revenue of 36 lacks of rupees. The ſoil is flat, moiſt, and fertile, and the heat exceſſive. Oriſſa is nominally one of the Britiſh provinces, though only a ſmall part of it is ſubject to the Bengal government. The diſtricts of Midnapour are poſſeſſed by the Britiſh nation; the remainder being in the hands of the Mahrattas, and their tributaries.

ORISTAGNI, or ORISTANO, a town of the iſland of Sardinia, ſituated on the weſt coaſt, on a gulf to which it gives name; the ſee of an archbiſhop; fortified, but thinly inhabited; 38 miles N.W. of Cagliari. N. lat. 39° 48′. E. long. 8° 50′.

ORISTAL, a river of Mexico, which runs into the bay of Honduras, N. lat. 15° 48′. W. long. 86° 35′.

ORITES, in *Botany*, ὀρείτης, *inhabiting hilly places*, Brown Tr. of Linn. Soc. v. 10. 189. Prodr. Nov. Holl. v. 1. 387.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juſſ.

Eſſ. Ch. Petals four, equal, recurved at the ſummit. Stamens inſerted above the middle of the petals, prominent.

Nectariferous glands four. Germen ſeſſile. Style ſtraight. Stigma obtuſe, vertical. Follicle leathery. Seeds two, winged at the top.

1. O. *diverſifolia*.—Leaves flat, lanceolate, toothed or entire, ſlightly downy beneath. Suture of the follicle abrupt.—Native of the higheſt mountains of Van Diemen's land.

2. O. *revoluta*.—Leaves revolute, linear, entire; clothed with hoary down beneath. Suture of the follicle rounded.—Found in the ſame country.

Theſe are ſhrubs, with alternate *leaves*, which are either entire or toothed. *Spikes* axillary or terminal, ſhort, compoſed of pairs of hermaphrodite *flowers*, each pair accompanied by one *bractea*. *Brown*.

ORITES, in *Natural Hiſtory*, the name of a ſtone deſcribed by the ancients, and celebrated by the writers of the middle ages for its wonderful virtues. Pliny ſays, that it was round, and remained unhurt in the fire, and that ſome called it *ſideritis*. To this the later writers have added, that there are three kinds of it: the firſt round and black; this, rubbed over with oil of roſes, was famous for the bites of venomous beaſts. The ſecond was green, variegated with veins and ſpots of white; this was to be annexed to the bodies of perſons, to preſerve them from many ſorts of injuries. And the third was compoſed of parallel plates, and ſaid to have the virtue of cauſing abortion, if only carried in the pocket.

ORITORIUS LAPIS, a name given by Ludovicus Dulcis, and ſome other authors, to the *ochreoferreous ætitæ*, or eagle ſtones; particularly to a ſpecies of them common in Germany, and uſed in the ſhops there, and in ſome other places, under the name of eagle ſtones. Theſe are of a browniſh colour and ſmooth ſurface, and are eaſily broken, being only compoſed of a thin cruſt of ferruginous earth, encloſing ſeveral ſmall lumps of a greeniſh marle, which rattle in it when ſhaken.

ORIXA, in *Botany*, a genus of Thunberg's, whoſe name is of uncertain derivation. Schreber, on the authority of Dahl, ſuggeſts that it may poſſibly be the ſame plant as Thunberg's *Othera*. Thunb. Nov. Gen. 56. Fl. Japon. 3. Schreb. 82. App. 820. Willd. Sp. Pl. v. 1. 672. Juſſ. 425.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, four-cleft, very ſhort. *Cor.* Petals four, lanceolate, ſpreading. *Stam.* Filaments four, ſhorter than the petals; anthers globoſe. *Piſt.* Germen ſuperior; ſtyle erect, ſhorter than the petals; ſtigma capitate, obtuſe. *Peric.* unknown, but moſt probably a capſule.

Eſſ. Ch. Petals four, lanceolate, flat. Calyx four-cleft. Stigma capitate. Capſule?

1. O. *japonica*. Linn. Syſt. Veg. ed. 14. 158. Thunb. Fl. Japon. 61.—Native of Japan. *Stem* ſhrubby, about ſix feet high, ſmooth, erect, branched *Branches* alternate, ſmooth, the extreme ones hairy. *Leaves* alternate, ſtalked, ovate, undivided, green above, paler beneath. *Flowers* in alternate, greeniſh cluſters, an inch long. *Bracteas* concave, oblong, ſmooth, under the partial flower-ſtalks, which are hairy as well as the common ſtalk.

ORIZAVA, or ORISABA, in *Geography*, a town of Mexico, in the province of Tlaſcala, ſituated in a fertile valley, ſurrounded with detached mountains, overſhadowed with the moſt verdant foreſts, containing a population of 3000 whites, and 1500 Indians and Negroes. The town is about 1500 fathoms in length, and 500 in breadth, with wide, neat, and well paved ſtreets. Great quantities of tobacco are produced in the vicinity. It has ſome tanneries and manufactures of cloth; 55 miles S.E. of Puebla de los Angelos. Orizava is on the high road between Vera Cruz and Mexico, being, according to Alcedo, 46 leagues to the eaſt of the capital. In its vicinity is a volcano, which is regarded as the moſt majeſtic in the vice-royalty. D'Auteroche obſerves, that the mountain Orizava is ſaid to be the higheſt in Mexico; and its ſnowy capital is viſible from the capital, a diſtance of 60 miles. This celebrated mountain is to the ſouth-eaſt of Mexico, not far from the road to Vera Cruz. It became volcanic in 1545, and continued for 20 years; ſince which time there has been no appearance of inflammation. Although the ſummit be clothed with perpetual ſnow, the ſides are adorned with beautiful foreſts of cedars, pines, and other trees. Clavigero notices its conic form, which is obſerved at ſea at the diſtance of 50 leagues. Some think it higher than the peak of Teneriffe. The detached mountains, called by the Mexicans Popacatepec and Iztaccihuatl, are alſo to the ſouth-eaſt of the capital, at the diſtance of about 30 miles, and are both volcanic. The crater of the former is ſaid to be half a mile wide, and celebrated for ancient eruptions. Both are covered with perpetual ſnow.

ORIZEUS COLOR, a term uſed by authors to expreſs the yellow colour of the eyes and urine of perſons afflicted with a jaundice.

ORKEDAL, in *Geography*, a town of Norway, in the province of Drontheim; 18 miles S.W. of Drontheim.

ORKEL, a river of Norway, in the province of Drontheim, which runs into the bay of this name; 14 miles S.W. of Drontheim.

ORKENUD, a town of Sweden, in the province of Schonen; 24 miles N. of Chriſtianſtadt.

ORKIANI, a town of Curdiſtan; 36 miles E.N.E. of Erbil.

ORKNEY BEANS, in *Natural Hiſtory*, a name given by authors to a ſort of fruit found on the ſhores of the Orkney iſlands near Scotland. Theſe are of ſeveral diſtinct ſpecies, and are none of them the produce of thoſe iſlands, nor of any places thereabout, but are probably of American origin, many of them being plainly natives of Jamaica.

They are found principally on thoſe coaſts which are moſt expoſed to the waves of the great ocean, and are on theſe ſo plentiful, that they might be gathered in large quantities, if of any value; but the only uſe they are put to, is to making of ſnuff-boxes out of them. Sir Robert Sibbald, and Mr. Wallace, in their accounts of Scotland, have both named them under the title of Molucca beans.

ORKNEY, or *Orknay Iſlands*, in *Geography*, a cluſter of iſlands, ſituated in the northern ocean, between the coaſt of Caithneſs, the moſt northerly county of the main-land of Great Britain, and the Shetland iſles, are diſtant from the former about four, and from the latter nearly twenty leagues. The latitude of the chief town, Kirkwall, is computed to be 59° 9′ N., and the longitude 2° 30′ W. from the meridian of Greenwich. From the force of the ocean, their form, as may be ſuppoſed, is extremely irregular. Their ſize alſo varies greatly; ſome of them being mere iſolated rocks, incapable of human habitation; while others are ſeveral miles in circumference. Pomona, or the Mainland, extends above 30 miles in length from eaſt to weſt, and diſcovers, throughout that ſpace, a conſiderable degree of diverſity in point of appearance, ſoil, culture, and elevation.

According to the moſt accurate ſurveys, the whole iſlands, compoſing this intereſting group, are ſixty-ſeven in number; twenty-eight of which are inhabited. The remaining thirty-nine are denominated holms, and are appropriated to paſturage, during the ſummer months. The names of the inhabited

inhabited iſlands are Pomona or the Mainland, Graemſay, Hoy, Waas, Ruſſay or Riſſay, Farray, Cavay, Flotay, South Ronaldſay, Swannay or Swinna, Pentland, Skerry, Burray, Lamon or Lambholm, Copinſay, Shapinſay, Stronſay, Papay-Stronſay, Eday, Faray, Sanday, North Ronaldſay, Weſtray, Papay-Weſtray, Eagleſhay, Rouſay, Weir, Enhallow, Gainſay, and Damſay. The chief of theſe will be found deſcribed under their reſpective appellations, in preceding or ſubſequent pages of this work.

Hiſtory.—The period at which the Orkney iſlands were firſt made known to the civilized world is not recorded in the works of any ancient author. Dr. Barry, however, deems it more than probable that they were diſcovered by the Carthaginians, or by the ſpirited Greek colony at Marſeilles, ſeveral centuries previous to the Chriſtian era. But whether they were inhabited at that time, is a queſtion which the ſame writer admits it to be impoſſible to determine; though he is of opinion that they were, and thinks it moſt likely that the original inhabitants came hither from the north of Scotland. At all events, there is no doubt of their having been known to the later Greeks, and to the Romans. Herodotus mentions Britain in general. Diodorus Siculus takes notice of Scotland in particular, mentioning cape Orcus, or Dunnet, the moſt northern promontory of Caithneſs, from which theſe iſlands can be diſtinctly ſeen; and Pomponius Mela points them out under the name of Orcades, which is to this day their Latin appellation. Buchanan and ſome other authors mention the names of ſeveral kings, who reigned over theſe iſlands during the firſt five centuries of the Chriſtian era. And in the diviſion of the Roman empire among the ſons of Conſtantine, the Orcades are claſſed with Britain, Gaul, and Spain, in the enumeration of thoſe countries which fell to the lot of young Conſtantine.

Theſe circumſtances tend ſtrongly to ſhew that the Orkneys were formerly conſidered as an ancient kingdom; but of their hiſtory throughout this period, nothing can be affirmed with certainty, except that they were inhabited by the ſame race of people, who, under the denomination of Picts, occupied the whole eaſtern coaſt of Scotland, forming two diſtinct monarchies, ſeparated from each other by the Grampian hills. To the more northern of theſe ſovereignties the iſlands were tributary, in the eighth and ninth centuries. Towards the cloſe of the latter, however, they were reduced under the dominion of Norway, by Harold Harfager, who likewiſe ſubdued the weſtern iſlands and the Iſle of Man. This prince conferred the hereditary government of his new conqueſts on Ronald, count of Merca; but that nobleman immediately reſigned them in favour of his brother Sigurd, whom the king, at the ſame time, created earl of Orkney.

By the nature of this grant, Sigurd, though tributary to the king of Norway, was in effect as independent as any ſovereign prince, and could levy troops and make war at his own pleaſure. Accordingly he turned his arms againſt Scotland, and reduced under his ſway the whole of Caithneſs and Sutherland. This earl was ſucceeded by his ſon Gottorm, who dying without iſſue, the earldom reverted to his uncle Ronald, by whom it was given to Hallad, one of his own ſons. His government was marked with timidity and weakneſs. Inſtead of exerting himſelf to repel the inroads of the numerous pirates who infeſted the iſlands, he ſhut himſelf up in one of his caſtles, and at length abdicated the government, and returned to Norway. Einar, his brother, now obtained the earldom. The adminiſtration of this earl was as vigorous and wiſe as that of his predeceſſor had been weak and impolitic. He introduced many improvements into the iſlands, and not only freed them from piratical invaſion, but, throwing off the Norwegian yoke, on account of the murder of his father, rendered himſelf independent of that kingdom. Sigurd left three ſons, the two eldeſt of whom were ſlain in battle, ſhortly after their father's death; ſo that the earldom devolved upon Thorfin, the youngeſt. This earl lived in peace during his whole life; but after his death, the iſlands were diſtracted by the contentions of his ſons. At length the death of the others gave the undiſputed poſſeſſion of the earldom to Landver, who married the celebrated Audna, daughter of Kiawala, one of the kings of Ireland. By this princeſs he had one ſon, Sigurd, his ſucceſſor, who was one of the moſt illuſtrious men of his age. He fell in battle at Clontarf, near Dublin, and was eventually ſucceeded by his youngeſt ſon Morfin, who maintained the glory of his father's name. He left two ſons, Paul and Erlend, who lived in the utmoſt cordiality, till their friendſhip was diſturbed by the ambition of Hacon, the ſon of Paul. This young nobleman went over to Norway, where, as well as in Sweden, he acquired great military reputation. During his reſidence in the former country, he repreſented to king Magnus the advantages which would accrue from a weſtern expedition. That prince accordingly ſailed for Orkney, and diſpoſſeſſing the two earls, appointed one of his own ſons viceroy in their ſtead. He then made excurſions into Scotland, Ireland, and England, accompanied by Hacon, and his two couſins, Erlend and Magnus. This laſt was highly diſtinguiſhed for his learning and piety, which ſo much excited the envy of Hacon, that he cauſed him to be murdered. Soon after he obtained the earldom. Hacon had two ſons, Paul the Silent and Harold the Orator. The latter ſucceeded in Caithneſs, and the Orkneys were governed by Paul, till the deceaſe of the former, by his own imprudence, gave the entire ſovereignty to Paul. Another competitor for the earldom, however, ſoon after appeared. This was Ronald, the nephew of the murdered Magnus, who, after a long ſtruggle, ſucceeded in obtaining poſſeſſion of the iſlands, and built the noble cathedral of St. Magnus, his uncle having been previouſly canonized by the pope. But Ronald did not long continue ſole maſter of the iſlands, being induced by motives both of policy and juſtice to take young Harold, the heir of Paul, as a partner in the earldom. Theſe noblemen lived amicably together, but found great difficulty in maintaining their poſſeſſions againſt other pretenders. At length, however, Harold, who ſurvived Ronald many years, rendered himſelf ſo powerful, as to be able to levy war againſt the king of Scotland, and to wreſt Caithneſs once more from that monarchy. Harold died in the 73d year of his age, and with him ended the independent ſovereignty of the Orkneys; for though ſeveral earls of the Norwegian race governed after him, they were compietely under the controul of the ſovereigns of Norway.

The laſt reſident earl of Orkney was Magnus V., at whoſe death, in 1379, the male line became extinct, and Henry Sinclair of the family of Strathearn, a deſcendant by the female line, ſucceeded to the title. Caithneſs and Sutherland were now alienated for ever to the crown of Scotland; and the kings of that country ſoon after claimed the ſovereignty of the iſlands alſo. This, however, they did not obtain till the reign of James III., who having married a daughter of Eric, king of Denmark, Orkney and Shetland were pledged in payment of her dowry, which was never paid; and conſequently both theſe cluſters of iſlands have, ſince that period, formed a part of the Scottiſh monarchy, and followed its deſtiny. The earls, however, retained for ſome time longer many of the high privileges annexed to their ſtation; but theſe alſo, and even the title,

were eventually renounced, in exchange for other poſſeſſions and honours. Queen Mary attempted to confer theſe iſlands, with the title of duke, on her favourite the earl of Bothwell, when ſhe intended to marry him. James VI. gave them to Patrick Stewart, at whoſe attainder they again reverted to the crown, and were afterwards granted to the earl of Morton. In this family they continued till the year 1766, at which time they were ſold to the father of their preſent proprietor, lord Dundas.

Geology and Mineralogy.—The eaſtern coaſt of the iſlands is low, and generally flat. As the ſhore advances to the weſt, the land is ſo elevated, as, with a few interruptions, to form itſelf into a range of hills, the higheſt of which is about 1200 feet in perpendicular height from the ſurface of the ſea. The ſhores in this quarter are bold and ſteep, and preſent many ſcenes truly ſublime. In ſome places they remain entire; but in others, having yielded to the force of the ocean, and the ravages of time, they appear ſhattered into a thouſand pieces, formed into majeſtic arches, or hollowed out into dark and unfathomable caverns. From the diſpoſition of the ſtrata, and many other conſiderations, little doubt can be entertained but that theſe iſlands, in remote times, were connected with each other, and alſo with the main-land of Scotland.

Both in the iſlands to the north of Pomona, and in thoſe ſouth from it, the ſtrata conſiſt chiefly of ſand-ſtone, ſand-ſtone flag, ſchiſtoſe, clay, and lime-ſtone, together with ſome mixture of baſalt and breccia. The ſand-ſtone, which is very plentiful, is in ſome places red, and in others of a dirty grey colour. The lime-ſtone and baſalt generally lie under a ſtratum of ſand-ſtone; and ſo little metallic ore does this group afford, that almoſt the only veins of any conſequence, hitherto diſcovered, are two of lead in the iſland of Shapinſay, and ſome iron-ſtone in Hoy. The ſtrata of the main-land are ſimilar to thoſe in the other iſlands; but it likewiſe contains ſome ſlate, granite, marble, and alabaſter, and is more abundantly ſupplied with metallic ores. A large rock, of rather ſingular character, ſtands at the weſtern entrance of the Pentland frith. The ground of this rock is of various colours; brown, red, grey, white, yellow, and greeniſh. Small rounded pebbles, generally quartz, of a white colour, are diſſeminated through it; and fragments of granite and other ſtones are immerſed in it, in various places. Veins and detached nodules of white calcareous ſpar are likewiſe frequent. In ſome parts it is rudely ſtratified, but in general is a ſhapeleſs maſs or blotch. Being ſuſceptible of a fine poliſh, cups, vaſes, and ornamental trinkets, are formed from it.

Soil and Climate.—The ſoil of the Orkney iſlands is more various, probably, than in any other diſtrict of Great Britain; and theſe varieties are ſo intermixed, that ſcarcely a ſingle farm is in this reſpect uniform. All the ſoils are thin or ſhallow, being ſeldom more than one or two feet deep; but they are neverthelefs uncommonly fertile. The rocks upon which the ſoil reſts, and which in many places are ſo ſoft and friable as to break before the plough, appear by their decompoſition to prove favourable to vegetation, or to afford food for plants.

Though ſituated ſo much to the north, the climate of theſe iſlands is not liable to thoſe extremes of heat and cold, which prevail in continental countries, leſs diſtant from the equator. This fact is the reſult of the proximity of every part of them to the ocean. The medium temperature, as appears by the ſprings, amounts to 45°; and the whole range, between the loweſt point of cold in winter and the higheſt of heat in ſummer, is from 25° to 75° of Fahrenheit's thermometer. The moſt prevalent winds here blow from the ſouth-weſt and ſouth-eaſt, in the ſpring, ſummer, and harveſt months; but during the reſt of the year, northerly winds are moſt frequent. Calms ſeldom occur for any length of time; and the winds, from whatever quarter they blow, or in whatever ſeaſon, are ſcarcely ever tempeſtuous, though often loud and ſtrong; a circumſtance which contributes greatly to the ſalubrity of the atmoſphere. Rains fall here in conſiderable quantity, and more on the weſtern than on the eaſtern coaſt. Snows are neither frequent nor of long duration; but they come with uncommon violence, and generally from the north-weſt and ſouth-eaſt quarter of the heavens. One peculiarity with reſpect to this ſubject is, that ſnow and hail are very prevalent for about a fortnight in the month of June. They are accompanied by a ſtrong piercing wind from the north, which, deſtroying the buds and their bloſſoms, checks the progreſs of vegetation, and clothes the fields with the appearance of approaching winter. The cauſe of this extreme and ſeemingly unnatural cold is the diſſolving of the immenſe fields of ice, in the northern ocean, happening at this ſeaſon, and the conſequent abſorption of heat, occaſioned by the change of that body from the ſolid to the fluid ſtate. About 50 years ago, the inhabitants were thrown into great alarm, by the fall of what was termed black ſnow, during this period. The phenomenon, however, was ſoon afterwards explained, and their fears allayed, by an account of an eruption of mount Hecla, in Iceland, having taken place on the day previous, which no doubt was the ſource whence the ſnow derived its unuſual hue. Thoſe who may be inclined to doubt this view of the fact, on account of the diſtance, will do well to conſult Buffon (Natural Hiſtory), who diſtinctly ſtates, that in ſome of the eruptions of mount Ætna, or Veſuvius, the aſhes have been carried by the winds to the ſhores of Egypt.

Another ſtriking peculiarity in the climate of theſe iſlands is, that thunder and lightning, the uſual concomitants of hot and ſultry weather, are ſeldom obſerved here in ſummer; but, in direct contradiction to the apparently general law of nature, are common in winter, and then only when the elements are in commotion. To what cauſe this anomaly ought properly to be referred, is yet a queſtion of uncertainty among natural philoſophers. Experience, however, has ſufficiently teſtified that their appearance in the cold ſeaſon has no effect in rendering them either more violent or deſtructive than in other parts of the globe. They are not accompanied by hail-ſtones of ſuch magnitude, nor have they ſuch a tremendous glare, nor ſuch loud and awful peals, as in more ſouthern climates.

From the proximity of theſe iſlands to the north pole, the days here in ſummer are of extreme length, but thoſe of winter are ſhort in proportion. The long abſence of the ſun, however, throughout this ſeaſon, is in ſome meaſure compenſated by the great luſtre of the moon, during her periods of ſhining, and by the ſcarcely leſs tranſcendent brilliancy of the aurora-borealis, which ariſes almoſt every unclouded night in the harveſt, winter, and ſpring months, and is of incalculable advantage to the navigation of thoſe ſeas, which are perilous only when want of light renders it impoſſible for the ſeamen to aſcertain the poſition of their numerous rocks, or to enter one of the excellent harbours with which almoſt every iſland abounds. For ſome account of this phenomenon, ſee AURORA-*Borealis*.

Tenure of Lands.—Landed property in Orkney is held in a variety of forms, which may, however, be generally reduced to three: crown-lands, church-lands, and udal-lands. The firſt were anciently the private property of the earls, but came in the courſe of time to be feued out, or granted

in perpetuity to vaſſals, who are bound to pay for ever the old rents. The church-lands are thoſe which formerly belonged to the biſhops and clergy, and which are now held by individuals, whoſe anceſtors had obtained them in feu or perpetuity, for payment in kind of the original rents. The udal-lands are thoſe poſſeſſed without any written charters. This tenure occurs alſo in Shetland, and in the town of Lochmaben. Hence it would appear that the feudal ſyſtem had never fully penetrated to theſe iſlands. The udallers, however, are comparatively few in number: ſome of them pay a trifling rent to the crown or church, but many pay to neither. Several of the larger, and many of the ſmaller, proprietors cultivate their own grounds; but the far greater proportion of the lands is let out to tenants; the larger farms on leaſes of ſeven, fourteen, or nineteen years, and the leſſer ones uſually at will. The ſize of farms in tillage varies from two acres to two hundred: an average ſize may be about eight acres in cultivation to each farm.

Agriculture.—The great irregularity of form diſcernible in theſe iſlands renders it almoſt impoſſible to compute the number of ſquare miles, or of acres they may contain. An attempt to effect this object has been made, however, by Templeman; according to whom, the whole group compriſes 384,000 Engliſh acres, of which only 24,000 are arable, and 60,000 laid down in paſture. The remainder is occupied by heath, and moſs, and by houſes, walls, roads, water, &c.

The uſual grains cultivated in the Orkneys are grey oats and bigg or bear; and theſe in alternate crops, without intermiſſion. Fallowing is very ſparingly practiſed by the larger farmers, but not at all by the ſmaller ones. A few acres of turnips are ſown annually; and from the abundance of the produce, the ground and climate would ſeem to be peculiarly adapted to that crop. The manure in ordinary uſe is ſea-weed. Lime and marle, though ſufficiently abundant, and eaſy of acceſs, are ſcarcely ever uſed; and even the dung of animals is neglected, in compariſon of their favourite ſea-weed. Draining is a cuſtom totally unknown. In ſhort, neither the ſcience nor the practice of agriculture is yet underſtood in this part of the Britiſh empire; nor is it probable that much improvement will take place, ſo long as the payment of rents and duties is managed on the preſent ſyſtem. In a country ſo ſituated as the Orkneys, the farmer has obſtacles enough to combat of a phyſical nature, and requires more than ordinary incentives to vigorous exertion. To clog him, therefore, with civil burdens, is to extinguiſh every feeling of which induſtry is the reſult.

The inſtruments made uſe of here for agricultural purpoſes are lamentably deficient. The ſame plough, which was formerly univerſal, is ſtill common. It has only one ſtilt, without either wreſt or mould-board; and its other parts are joined in ſuch a form, that it does not poſſeſs a ſingle quality to recommend it but its ſimplicity, and the low price at which it can be purchaſed. This awkward tool is drawn by three or four ſmall horſes abreaſt, with the driver moving backwards before them. The harrows are very ſmall and light, and often have wooden teeth, even where the ſoil is ſtrongeſt. The roller is little known, being uſed only by a few of the great farmers. For ſome further remarks on the agriculture of theſe iſlands, ſee Pomona.

Botany.—To enumerate all the indigenous plants, which have been obſerved in the Orkneys, would far exceed the limits allotted to an article of this kind. Thoſe uſually raiſed for convenience, or ornament, differ little from ſuch as are met with in ſimilar ſituations, in other parts of Scotland. Bear or bigg and oats are the kinds of grain moſt commonly cultivated; but to theſe, though in very ſparing quantities, are ſometimes added peaſe, beans, wheat, rye, and flax, on the grounds of the more enterpriſing gentlemen farmers. The ſame deſcription of perſons likewiſe raiſe tares, ſaintfoin, lucern, cabbage, turnips, and different ſorts of clover and rye-graſs. In the flower-garden, the roſe, the tulip, the carnation, the pink, and a multitude of other flowers, are cultivated with ſucceſs; and the kitchen-garden produces cabbage, brocoli, cauliflower, peaſe, beans, ſpinnage, leeks, onions, turnips, carrots, parſnips, celery, and artichokes. The fruit-garden affords excellent black, white, and red currants: the other fruits, however, are very inferior both with reſpect to ſize and flavour. Of trees there are only a few in Hoy; and theſe, on account of their ſtunted growth, ſcarcely deſerve the name: and ſome of larger dimenſions in the gardens around Kirkwall. This fact would excite little ſurpriſe, if the moſt unequivocal evidence of their former exiſtence here, in great plenty, were not derived from hiſtory, and from the number of trunks dug up in the moſſes. The opinion ſo commonly entertained, that trees will not grow in the Orkneys, is completely erroneous. When proper attention is paid to the early growth of the young ſhoots, its fallacy will ſoon become manifeſt. The failure of the attempts hitherto made has been the conſequence of neglect, or of the want of judgment in planting in ſituations too much expoſed to the violence of the weather, or of the ſea ſpray.

Zoology.—The quadrupeds of theſe iſlands are the horſe, the ox, the ſheep, the hog, the dog, the cat, the otter, the ſhrew-mouſe, the role-mouſe, the field-mouſe, the Norwegian rat, the rabbit, and the ſeal. The horſe is preciſely ſimilar in appearance and qualities to that of Shetland. (See Mainland *of* Shetland.) The ox is of a very ſingular breed, and altogether different from any kind known in other parts of Great Britain. This animal is of a very diminutive ſize, but ſtrong and hardy; and is ſuppoſed to have originally come from the Scandinavian ſhores. The ſheep is likewiſe a peculiar breed, and, from ſome features in its character, appears to be ſprung from the ſame ſtock with that of Iceland, the Ferroes, and Shetland. It is reared entirely in a wild ſtate, and hence is extremely ſmall; the whole carcaſs ſeldom weighing more than 36 pounds. The hog is very different from the ordinary ſpecies bred in Scotland. Its back is highly arched, and covered with a great quantity of long, ſtiff briſtles; the ears erect and ſharp pointed, and the noſe amazingly ſtrong. The hair of this animal is an article of conſiderable value: it ſerves as an excellent ſubſtitute for hemp, in making ropes to anchor fiſhing-boats.

The brown or Norwegian rat has been introduced by the ſhipping that frequents the iſlands, and has nearly baniſhed the common black rat. From the tip of the noſe to the point of the tail it meaſures about 18 inches. This animal diſplays great fierceneſs, and has even been known to brave the attack of man. Rabbits are ſo abundant here, that their ſkins form a conſiderable branch of commerce. Their colour is uſually brown; an entirely white one is ſeldom ſeen. Though devoured by various animals of prey, the ſtock never ſeems to ſuffer any diminution. The caſe, however, is very different with the hare, which was formerly an inhabitant of the Orkneys, but has entirely diſappeared within the laſt two centuries. Seals are common in all the ſmall iſlands, or holms, and are valuable for their ſkins and oil. Hams, made of young ſeals, are much reliſhed by the natives.

The domeſtic birds are dung-hill fowl, ducks, geeſe, turkeys, and a few peacocks. The wild birds conſiſt of an immenſe

immenſe variety of land and ſea-fowls, both migratory and indigenous. In ornithology, indeed, the Orkneys conſtitute the moſt intereſting diſtrict in the Britiſh iſles. It is the general breeding-place of our native water birds; and in the towering cliffs and precipices of many of the iſles are numbers of eagles, falcons, and owls. Swans alſo are abundant, during winter, in the freſh-water lakes. Mr. Bullock, the proprietor of the London Muſeum, has lately enriched his valuable collection by many beautiful and rare ſpecimens from theſe remote iſlands, where he ſpent a great part of the ſummer of 1812. In the awful cliff he found every ſpecies of Britiſh eagle, except the oſprey; and brought away ſeveral of the young birds, as well as thoſe of the peregrine falcon. The great northern diver frequents the bays of this iſle; and thoſe rare Britiſh birds, the red-throated diver and the arctic gull, breed on the edges of the freſh-water lakes. In North Ronaldſay the gentleman above mentioned diſcovered, and added to the Britiſh Fauna, the majeſtic ſtrix nyctea, or great ſnowy owl of Hudſon's Bay. In the marſhes of Sanda he found the neſt of the beautiful little red phalarope. The great black-backed gull breeds in the Souliſkerry, a low flat iſle ſituated 10 leagues from Hoy. Here were ſeen ſuch myriads of birds, that they darkened the air; and it was difficult to walk, without deſtroying their eggs. In the ſmall holm of Papay-Weſtray were diſcovered the king-duck, the eider-duck, ſo valuable for its down, and the only ſpecimen of the great auk Mr. Bullock ever ſaw on the Britiſh ſhores. Grous are common in all the mountainous iſles, but partridges are unknown. The ſtormy petrel, or Mother Carey's chick, breeds in the rabbit-holes on ſeveral of the iſles. The peregrine is diſcovered on head-lands and inacceſſible precipices: never more than one pair and their offſpring inhabit the ſame rock; and as ſoon as the young ones have acquired ſufficient ſtrength, they alſo are driven away by their parents to ſeek new places of habitation for themſelves. When falconry was in vogue, this noble kind of hawk was frequently carried hence for the amuſement of the Scottiſh monarchs. In ſuch eſtimation, indeed, was it held, that when the earldom was diſannexed from the crown by act of parliament, all hawks were reſerved to his majeſty, with the falconer's ſalaries; and accordingly, even at this day, a hen from every houſe here is paid annually to the royal falconer.

Among the eagles which abound in Orkney, the ſpecies called the ring-tail eagle is moſt remarkable. It is diſtinguiſhed from the other kinds, by a band of white encompaſſing the root of the tail, and by the feathers covering its legs to the very feet. This bird is ſo prodigiouſly ſtrong, that he has been known to carry off, not only large fowls, but lambs, pigs, and even children. So great was the devaſtation committed by him in ancient times, that a law was paſſed, aſſigning a conſiderable reward to any perſon who deſtroyed a neſt, or one of the birds. In the exhibition of the Royal Academy of London, 1813, was a very fine and intereſting picture, from the pencil of G. Dawe, A.R.A., repreſenting a mother reſcuing an infant child from the neſt of one of theſe eagles.

The dexterity of the natives in catching the various kinds of aquatic fowls is ſurpriſing, and the attempt is apparently fraught with the utmoſt danger. Sometimes an individual is lowered down by a rope, from the ſummit of a precipice, to the place where the birds neſtle. At other times, one party proceeds in a boat to the foot of a rock, while another is ſtationed on the top. Thoſe on the ſummit are provided with two ropes, which are thrown down to their comrades in the boat, who faſten them to the upper corners of a large net. The net is then hoiſted up, ſo as to cover the rock on which the birds are ſitting; and as ſoon as this has been effected, a noiſe is made with a rattle by the boatmen below. The fowls, terrified at the ſound, fly into the boſom of the net, in which they are inſtantly incloſed, and lowered down into the boat.

The marine animals, which haunt the coaſt of theſe iſlands, are no leſs various than the birds which frequent their rocks. Lobſters and crabs are diſcovered in great abundance. Of the former fiſh, many thouſands are ſhipped for the London market every week. The coal, cod-fiſh, and haddock, are plentiful, and ſo likewiſe are herrings; but notwithſtanding the great advantage which might accrue from theſe fiſheries, very little attention is paid to this ſpecies of induſtry. Skates are found here from one to five feet in diameter. The grampus is ſeen in great numbers in moſt of theſe coaſts, and particularly in ſtrong and impetuous currents. The ſize of theſe animals is from fifteen to twenty-five feet in length, and they are very thick in proportion. Its appetite is ſo voracious, and its nature ſo fierce, that it will attack the largeſt fiſhes. The ſpermaceti whale, the bottle-noſe, and the round-lipped whale, are very frequently thrown on ſhore in theſe iſlands; a circumſtance ſuppoſed to be occaſioned by the attacks of the grampus. Herds of porpoiſes to the amount of a hundred and upwards are often ſeen together.

Natural Curioſities.—Among the curioſities of Orkney, the ſtupendous arches, and immenſe caverns formed by the ocean, are the moſt prominent, and cannot fail to attract the notice and excite the ſurpriſe of all who are ſtrangers to ſuch ſcenes. The Old-man-of-Hoy is probably as remarkable a monument of its kind as any in the univerſe. It riſes boldly from the ſea to the height of 1500 feet, and exhibits a perpendicular ſection of the ſand-ſtone ſtrata, built upon each other with all the regularity of architecture. In ſome aſpects it reſembles a rude pyramid, whoſe baſe has been narrowed by the waves; in others, it bears a ſtriking ſimilitude to the ruins of a vaſt cathedral, or of a turreted caſtle. Near the ſummit of this hill, in the ſummer months, ſomething is obſerved to ſhine and ſparkle with uncommon luſtre. The natives regard it as an enchanted carbuncle; and it is curious, that, though many perſons have clambered up the rock to aſcertain the occaſion of this appearance, they have hitherto failed in their object.

On the ſhores here are found a great number and variety of curious marine ſhells, and many ſtrange fiſhes, driven hither by the currents of the ocean. But the greateſt curioſity thrown by the ſea on theſe iſlands are the phaſeoli, commonly known by the name of the Molucca or Orkney beans. They are of ſeveral ſpecies, none of which are the produce of a northern climate, but are probably of American or Weſt Indian origin; many of them being natives of Jamaica. They are found chiefly on the weſtern coaſts, and are on theſe ſo plentiful, that they might be gathered in large quantities, if of any value; but the only uſe they are adopted for is the making of ſnuff-boxes. See ORKNEY *Beans*.

Exotic birds, the inhabitants of diſtant and warm climates, occaſionally viſit theſe iſlands; whither they have been doubtleſs forced by tempeſtuous weather. A Laplander, from the ſame cauſe, is ſometimes ſeen here, in his ſlender canoe, covered with ſkins. Fiſh, as large as whitings, are frequently thrown aſhore to a conſiderable diſtance within the land; and at Cantick Head, ſuch is the force of the meeting tides, that, in ſtormy weather, huge ſtones are often heaved up from the bowels of the deep, and caſt over the rocks upon the ſhore.

Ancient and preſent State of Religion.—Previous to the Norwegian

wegian invaſion, the inhabitants of Orkney appear to have been worſhippers of the ſun, and to have had Druids for their prieſts. That event, however, brought along with it the barbarous ſuperſtition of the north, or the worſhip of Odin. This god was ſuppoſed to delight in bloodſhed and war; and thoſe who fell in battle were deemed ſo many victims on his altars. Death in action was the ſureſt paſsport to his paradiſe, the pleaſures of which conſiſted of indulging in immortal drunkenneſs, accompanied with the triumph of victory, or of drinking ale to all eternity out of the ſkulls of an enemy.

To this horrid worſhip ſucceeded the milder doctrines of Chriſtianity, towards the end of the tenth century, when Sigurd was in poſſeſſion of the earldom. The manner in which its eſtabliſhment was effected affords a ſingular view of the manners of the age, and of the zeal with which that religion was propagated. Olaus Frigueſſon, who then filled the throne of Norway, having been converted while in England, and perceiving the ſuperior excellence of the Chriſtian creed and precepts, became inſpired with the moſt earneſt deſire of converting others. For this purpoſe, accordingly, he viſited Ireland; and on his return, brought his fleet to anchor in one of the harbours of South Ronaldſay, and ſent an invitation to Sigurd and his ſon to come on board his ſhip. The earl ſuſpecting no treachery, and confident in his acknowledged fame and power, inſtantly complied, imagining that the king wiſhed to hold a conference with him reſpecting ſome military enterpriſe. He was ſoon, however, undeceived, by Olaus telling him the object of his expedition, and declaring, that unleſs he and his people would immediately embrace the Chriſtian faith, he would deſolate his country, and put every heretic to death. Sigurd, though confounded at this unexpected threat, nevertheleſs anſwered with firmneſs, that he could not ſuffer himſelf to renounce his religion, ſanctioned as it was by the wiſdom of his anceſtors, until ſome ſufficient reaſons were offered why he ſhould be guilty of ſuch abjuration. The Norwegian monarch replied by ſeizing the ſon of the earl, and ſwearing he would plunge his ſword into his breaſt, if his father continued obſtinate: whereupon Sigurd agreed to his propoſals, and publicly profeſſed himſelf a Chriſtian. His example was followed ſhortly after by all the people; and, from that period, Chriſtianity conſtituted the religion of the Orkneys, which, with Shetland, ever after formed one biſhopric. Some of the prelates who filled this ſee were men diſtinguiſhed, not only as divines, but as eminent literary and political characters. Among the more celebrated of them were Robert Reid and Adam Bothwell. The former held ſome of the higheſt offices in Scotland, and was one of the commiſſioners ſent to witneſs the marriage of Mary, queen of Scots, with the dauphin of France. He left by will 8000 marks, for the purpoſe of founding a college in Edinburgh. Adam Bothwell, his ſucceſſor, was the firſt epiſcopal biſhop of the iſles. This prelate performed the marriage ceremony between queen Mary and Bothwell; and alſo inaugurated her ſon, king James, after ſhe was compelled to reſign her crown. By his aſſiſtance the Scotch laws were firſt collected into a body, and publiſhed; and when the unhappy differences occurred between the young king and his mother, during her impriſonment in England, he was choſen by the eſtates to aid the regent in bringing them to a termination.

So long as the Catholic and epiſcopal form of church government continued in theſe iſlands, eighteen ordinary officiating clergymen were ſtationed here. The ſame number was employed after the eſtabliſhment of preſbyterianiſm; moſt of whom had, as their ſucceſſors ſtill have, two or even three churches to occupy, frequently ſituated at conſiderable diſtances from each other, and ſeparated by branches of the ſea. Notwithſtanding this, however, divine ſervice is ſaid to be performed in all of them with becoming regularity. For ſome time ſubſequent to the change of religion, the whole clergy were united into one preſbytery; but they afterwards divided into two, and now form three preſbyteries, conſiſting of ſix miniſters each; the whole compoſing a provincial ſynod. The three preſbyteries chooſe each three members, and the borough one, to repreſent them in the general aſſembly. Lord Dundas is patron of all the pariſhes both of Orkney and of Shetland.

Civil Government.—Before the transfer of the Orkneys to the crown of Scotland, the inhabitants were governed by the laws, and adhered to the cuſtoms of Norway. Indeed, for a long period after they changed their maſters, theſe iſlands ſtill retained the ſame political conſtitution as before. The ſupreme court, called in the language of the country lawting, continued in the exerciſe of its legiſlative powers ſo late even as the time of the commonwealth, when it was entirely aboliſhed. The acts paſſed in this aſſembly, which are ſtill known under the name of county acts, are ſaid by Mr. Barry to diſcover much regard to the proſperity of the place, as police regulations, though lamentably defective on the ſubject of trade and commerce. The conſtitution of the lawting is ſuppoſed to have reſembled, in ſome degree, that of the tyndal-court, or houſe-of-keys, in the Iſle of Man. The preſident, or principal perſon of this court, was named the great foud, or lagman; and ſubordinate to him were ſeveral little fouds, or under-ſheriffs or bailiffs: and as the chief judge had a council, conſiſting of ſeveral members, called raddmen; ſo the inferior ones had their council alſo, compoſed of members denominated lagraetmen, or lawwrightmen, who were a kind of conſtables for the execution of juſtice in the reſpective iſlands. To theſe members were added, at leaſt latterly, the governors for the time, the gentlemen of the county, and even a certain number of the peaſantry, who, among a free people, claimed a vote in framing the laws that were to govern them.

The legiſlative enactments of the lawting have for many years totally fallen into diſuſe, and the deciſions of all the courts are now regulated by the principles and practice of the law of Scotland. Lord Dundas, as high ſteward or lord lieutenant of the county, which includes both the Orkney and the Shetland iſles, has the power of nominating certain judges called bailies, one of whom is eſtabliſhed in every iſland and pariſh. Theſe petty magiſtrates act as juſtices of the peace, and hold courts for the deciſion of civil pleas to the value of 16*s.* 8*d.* ſterling. All queſtions of higher import muſt be pleaded in the ſheriff's court, which is held at Kirkwall, uſually by the ſheriff-ſubſtitute; the ſheriff-depute, who is always a Scotch barriſter, and appointed by the crown, only viſiting his juriſdiction occaſionally, to determine ſuch cauſes as may chance to involve more difficult and abſtruſe points of law. Subſervient to the bailies are ſix or ſeven of the more reſpectable inhabitants, who act as conſtables, and ſuperintend the morals of the other pariſhioners. In Kirkwall, which is the ſeat of juſtice, there are, beſides the ſheriff's court, a commiſſary, a juſtice of the peace, and admiralty court. The commiſſary court is appropriated to pleas of an eccleſiaſtical nature, ſuch as divorces, marriages, &c. See SCOTLAND.

Towns, Repreſentation, &c.—The only towns or villages of any conſequence in the Orkney iſlands are Kirkwall and Stromneſs. Both theſe places are ſituated on the Mainland, and are ſuppoſed to contain nearly 3000 inhabitants each. The former is a royal burgh, and the capital of the county; but

but Stromneſs is merely a village, though it probably carries on more trade than Kirkwall. See KIRKWALL and STROMNESS.

The county is repreſented in the Britiſh parliament by one knight of the ſhire; and the burgh, in conjunction with four others, make choice of a burgeſs, who is likewiſe conſidered as the repreſentative of the inhabitants at large. Lord Dundas, as may be ſuppoſed, poſſeſſes the chief intereſt both in the county and burgh.

Population.—As there are no authentic data, by which the ancient population of theſe iſlands can be accurately aſcertained, the conjectures which have been hazarded on this ſubject afford very different reſults. When, however, the power of the earls, and the anxiety with which their alliance was courted, are taken into view, it ſeems reaſonable to conclude that it muſt have been very conſiderable. In a general muſter of the people by P. Stewart, earl of Orkney, it is ſaid that 10,000 men could be raiſed on any emergency, and as many left as were ſufficient for the agriculture and fiſheries. Guthrie, in his Hiſtory of Scotland, aſſerts that the ſame amount of perſons from this country carried arms, at the time of the great rebellion, in the 17th century. Theſe repreſentations, if admitted to be correct, would ſeem to ſwell the population beyond the bounds of probability. Dr. Barry, therefore, conſiders them as extravagant. It is certainly evident, however, that the population of the Orkneys has ſuffered a great decreaſe within the laſt century; and no leſs clear, that the iſlands are capable of ſupporting four times the amount of their preſent inhabitants, which, according to the parliamentary returns of 1811, were computed at 23,238 in number.

Manufactures and Commerce.—At the commencement of the laſt century, a very conſiderable manufacture of woollens is ſaid to have been carried on in theſe iſlands. This branch of induſtry is now much decreaſed, and confined entirely to a home conſumption. The articles manufactured are chiefly ſtockings and blankets, and a very coarſe kind of cloth worn by children, and by thoſe reſident in the country; for the inhabitants of the town almoſt univerſally wear Engliſh cloth. The linen manufacture was introduced about ſixty years ago; and though at firſt it met with an unfavourable reception, it ſoon triumphed over every oppoſition, and became very widely diffuſed, to the great benefit both of the manufacturers and of the labouring poor; many of whom muſt have periſhed for want, but for the timely ſupport it was the means of ſupplying. This improving condition of affairs continued for upwards of twenty years, when the manufacture ſuffered a temporary decline, by a competition among the manufacturers, occaſioning an undue riſe of wages, which ſeldom fails to be attended with a proportionate diminution of induſtry among an indolent people. The natural courſe of events has happily, however, corrected this evil; and the linen manufacture is now more extenſive, and better conducted, than at any former period. The quantity of linen cloth ſtamped annually exceeds 60,000 yards; and the amount of yarn ſold in the ſame ſpace, to the merchants of Newcaſtle, Edinburgh, and Glaſgow, and to itinerant purchaſers, is eſtimated at conſiderably above 100,000 ſpindles. Almoſt all the flax conſumed is imported from Ruſſia and Holland.

But the principal and moſt lucrative manufacture of the Orkney iſlands is that of *kelp*. This ſubſtance is chiefly valuable on account of the large quantity of ſoda it contains, which renders it uſeful in the compoſition of ſoap; in the manufacture of alum, and in the formation of crown and bottle glaſs; indeed in theſe manufactures kelp anſwers completely all the purpoſes of the very beſt potaſh. It is formed by burning certain ſpecies of marine plants; and affords employment to about three thouſand perſons of both ſexes during the ſummer months. Each of them makes in that period a ton, conſiſting of 24 cwt. of kelp, for which they receive, according to circumſtances, from 30*s.* to 3*l.*, ſo that the total quantity made every ſeaſon is ſomewhere about 3000 tons. The price at which it is ſold to dealers in the ſouth, varies from 8*l.* to 10*l. per* ton, including the expence of freights, inſurance, &c. which are moſtly effected by natives. Hence the profits accruing to the iſlands from this manufacture are calculated on an average at 25,000*l. per annum*. For ſome account of the proceſs of making kelp, ſee CARBONAT *of Soda*.

The Orkneys, from their ſituation, and from the excellence of their harbours, are certainly well calculated for a commercial connection, not only with the different trading towns of Great Britain, but with the north of Europe, and with America. Such a connection, however, cannot poſſibly ſubſiſt to any conſiderable extent, until an important amelioration of their agricultural and manufacturing condition takes place; and this, we fear, is not ſoon to be expected. Nevertheleſs, it is pleaſing to obſerve that the limited trade theſe iſlands poſſeſs is in a progreſſive ſtate of improvement. The principal exports are beef, pork, butter, tallow, hides, calf ſkins, rabbit ſkins, ſalt fiſh, feathers, linen, yarn, and coarſe linen cloth and kelp; and, in favourable ſeaſons, corn, meal, and malt. The imports are wood, iron, flax, coal, ſugar, ſpirits, wines, ſnuff, tobacco, flour, and biſcuit, ſoap, leather, hard ware, broad cloth, and printed linens, and cottons. In 1790 the exports were valued at 26,598*l.* 12*s* 0*d.* and the imports at 20,803*l.* 0*s.* 0*d.* prime coſt in the Engliſh and Scotch markets; but in 1800 the exports were ſtated at 39,677*l.* 9*s.* 4*d.* and the imports at 35,789*l.* 17*s.* 4*d.*

Obſtacles to Improvement, Weights, &c.—The chief obſtacle to the improvement and value of theſe iſlands, is the neceſſity the farmers are under of paying their rents in kind, and principally in grain. Hence it ariſes that the latter produce muſt either be raiſed on grounds which are far better adapted for the cultivation of graſs or green crops, than of corn; or the farmer muſt commute at a rate which renders his rent extravagant, and ſuch as wholly precludes him from realizing a reaſonable profit for his labour. This rate is the price brought by the beſt foreign grain, loaded as it is with freight charges and mercantile emoluments. To remedy this ſerious evil, which is alike prejudicial to agriculture, manufactures, and commerce, the intervention of the legiſlature is indiſpenſibly requiſite, as otherwiſe it is impoſſible to compel a fair converſion of the rents into money.

The weighing inſtruments of Orkney are likewiſe among the grievances which obſtruct the improvement of this territory. Theſe were brought from Norway at a very early period, and not only differ from thoſe in uſe on the Mainland, but the original ſtandards being loſt or deſtroyed, are themſelves fluctuating, and in ſome meaſure arbitrary. Theſe inſtruments are called the byſmer and pundler. The firſt conſiſts of a lever, or beam of wood, three feet long, and about three inches diameter from one end to near the middle, whence it tapers gently to the other end, which is not above one inch in diameter. From the middle, all along this ſmall end, iron pins are fixed at unequal diſtances, which ſerve to point out the weight of the body weighed. The pundler is ſo nearly ſimilar in form to the Statera-Romana, or Steelyard, as to ſuperſede any further deſcription, than merely to obſerve that the beam of which it is compoſed is about ſeven feet long, and between three and four inches in diameter. This inſtrument is employed in weighing malt, meal, beer, oats, and other groſs commodities; while the byſmer is made

uſe

uſe of for aſcertaining the weight of butter, oil, ſalt, wool, cheeſe, and ſuch other articles as are commonly purchaſed in ſmaller quantities. The loweſt denomination of weight is the mark, twenty-four marks make a ſetteen or liſpund, the higheſt quantity weighed by the byſmer, ſix ſetteens, a meil, and twenty-four meils a laſt. So intricate are theſe weights, and ſuch the uncertainty that attends them, that even the natives, moſt accuſtomed to weighing, find great inconvenience ariſing from the uſe of them, and differ materially concerning the exact weight of each denomination. Some contend that the mark, which is the radical weight of which all the reſt are multiples, ſhould weigh eighteen ounces, while others aſſert it ſhould weigh twenty-two. The latter, however, is the moſt juſt, as well as the moſt prevalent opinion; of conſequence the ſetteen, or liſpund, ſhould contain thirty pounds, and the meil eleven ſtone four pounds, Amſterdam weight.

Language, Manners, and Cuſtoms.—The ancient language of Orkney was derived from the Gothic, which generally ſpread itſelf over Germany and Scandinavia. It was called the Norſe, but ſeems to have been a diſtinct dialect from that ſpoken either in Denmark, Sweden, or Norway, though it had a much greater ſimilitude to the laſt than to the others; but whether this difference was the reſult of chance and time, or was owing to a mixture of the old Pictiſh language, are queſtions of no eaſy ſolution. Such as it was, however, it continued to be ſpoken in great purity for two centuries after the iſlands became annexed to the crown of Scotland. Some perſons were even to be found who could ſpeak it with perfect eaſe within theſe fifty years back. At preſent it is only to be traced in the names of places and perſons; the Engliſh language, with a Norwegian accent, and a great mixture of Scottiſh terms and phraſes, having become the common language of all the iſlands.

The manners of the gentry in this country differ very little from thoſe of the ſame claſs in Edinburgh, where indeed they moſt frequently receive their education, and imbibe thoſe habits and feelings, which are ſeldom obliterated under any circumſtances of human life. They are generally kind without careſſing, civil without ceremony, and reſpectful without compliment; they are obliging and hoſpitable to ſtrangers, and when no party differences interfere, (which are unhappily too frequent,) ſocial and friendly among themſelves. Dr. Barry characteriſes them as diſtinguiſhed for their good ſenſe and literary acquirements, but blames them much for their ſupine indifference on the ſubject of religion, in which reſpect, however, the ſame author obſerves, they differ entirely from their female companions, whom he holds up as models of innocence, induſtry, and economy, and no leſs alive to the tender ſenſibility that adorns their ſex, than ſuperior in underſtanding and perſonal attractions.

The ſecond claſs of perſons, conſiſting of thoſe denominated tradeſmen and ſhopkeepers, reſide moſtly in the two principal towns, only a few being ſcattered over the iſlands. The traders reſident in the country, Dr. Barry repreſents as decent, peaceable, induſtrious, honeſt people, who commonly unite the buſineſs of the farmer with that of retail dealer. The ſhopkeepers of Stromneſs are ſaid to bear the ſame character, but in Kirkwall, though undoubtedly many exceptions are to be found, dealers are unhappily deficient both in induſtry and education. A ſimilar remark may be applied to thoſe who follow mechanical employments in that town.

With reſpect to the third claſs, which comprehends all thoſe connected with the cultivation of the land, ſuch as farmers with their ſervants and cottagers, it may in general be obſerved that they are, in a high degree, indolent, wedded to old cuſtoms, averſe from improvement, dark, artful, intereſted, and more reſpectful to their ſuperiors from fear than attachment. But with theſe defects and vices are blended ſome good and amiable qualities. In point of underſtanding they are ſcarcely inferior to any peaſantry in Great Britain. They are faithful in the obſervance of the marriage vow, affectionate to their children, and uſually honeſt in their tranſactions with one another, though negligent in payment of their rents. Their faults are the reſult of their oppreſſed and mean condition, and of the frauds practiſed upon them by unprincipled dealers in the towns, or by itinerant merchants, to whom they are compelled to diſpoſe of their own produce, either in barter for other goods, or at a long and uncertain credit. One remedy for this evil would be the eſtabliſhment of regular markets in different parts of the iſlands, which at preſent are much wanted.

Like the common people in moſt other places, thoſe of Orkney, whatever profeſſion they follow, are extremely credulous, and more inclined to truſt quacks in every line than men regularly bred and diſtinguiſhed for their judgment and education. The ſame diſpoſition leads them to give implicit belief to all the abſurd and ridiculous tales which are ſo frequently circulated reſpecting witches, fairies, and other ſupernatural agents. Hence a multitude of charms are ſtill in practice to ſecure good fortune, relieve diſeaſes, or to ward off ſome real or imaginary danger. Some days of the week are lucky, and others ominous of misfortune. Thurſdays and Fridays are the only days on which they incline to enter upon the marriage ſtate; and they are anxious, in the higheſt degree, to avoid doing it except when the moon is waxing. When intending to kill an ox or a ſheep, they are careful that it ſhall be done during the firſt quarters of that luminary, conceiving that if it is delayed till the waning, the meat will be of an inferior quality. In ſetting out on a voyage, they always turn their boats in the direction of the ſun's motion, and utter a ſhort prayer. Though Preſbyterians in profeſſion, they ſtill retain many relics of Romiſh ſuperſtition, and have a great veneration for ancient places of worſhip, eſpecially ſuch as have been dedicated to favourite ſaints. Theſe they invoke to aſſiſt them in any emergency, and vow to perform ſervices, or preſent oblations to them if their prayer is granted. The feſtivals of the Popiſh calendar are obſerved with the utmoſt punctuality, not indeed as times of religious worſhip, but as days ſet apart for feaſting and conviviality. On ſome of theſe days they refrain from work, and on others, only undertake work of a certain kind, and for a certain period. At one time they muſt go fiſhing, at another they carefully avoid that ſort of employment; now they muſt eat fiſh, now fleſh, now eggs, milk, &c. according as the particular day, or ſeaſon, may require.

Antiquities.—From the hiſtorical importance of the Orkneys, at a very early period, and during ſo many centuries after the Norwegian conqueſt, it might readily be conjectured that they muſt contain numerous remains of antiquity of different kinds, and aſſignable to different ages. This is accordingly the fact, and we believe few diſtricts are more worthy than theſe iſlands of antiquarian inveſtigation. All the ſhores and headlands abound with thoſe buildings which have been denominated Picts-houſes; but the preciſe uſe of which is not yet determined by the reſearches of the learned. Sometimes they appear ſingle and detached, and at other times are collected together in conſiderable numbers. One of them, at Quarterneſs, near Kirkwall, on the Mainland, is minutely deſcribed by Dr. Barry. (See POMONA.) At Stennis alſo, on the Mainland, is one of thoſe circles of ſtones, commonly regarded as Druidical temples, and on this, as well as on moſt of the other iſlands, may be ſeen a

number of huge ſingle ſtone monuments, of which it is not eaſy to conjecture the origin or intention. They are uſually from twelve to twenty feet in height above ground, and five or ſix feet in diameter each way; and as moſt of them are placed on lofty ſituations, it may juſtly excite wonder, how, in the ignorance of mechanical powers, they could be brought hither and erected. As they bear no inſcription, or hieroglyphics, nor any marks of an inſtrument, but are as rude and unpoliſhed as when dug up from the quarry, it ſeems conſonant to reaſon to conſider them as the monuments of a very early age, when the people were ignorant of arts and of letters. And this is all that can be ſaid concerning them, for not even tradition affords the ſmalleſt clew to determine the purpoſe of their erection. Some indeed have hazarded the ſuppoſition that they were intended to mark the ſpot that contained the bones of a deceaſed prince or chieftain, or to ſerve as a boundary between the lands of one great man and another; but the firſt idea is rendered extremely improbable by the fact that no tumuli, urns, or graves, have hitherto been found near them; and it is ſcarcely poſſible to conceive that any ſet of men would expend ſo much labour on landmarks as the quarrying, removal, and fixing of ſuch immenſe maſſes muſt of neceſſity have required. The writer of this article is therefore inclined to regard them as belonging to the ſame claſs of antiquities with the circles of Stennis, Avebury, or Stonehenge, that is, either as monuments of religion, or memorials of ſome great national event. In the iſland of Weſtray, are a number of ſtone ſepulchres ſcattered over two extenſive plains. Some of them have been opened, and found to contain human bones, and a variety of warlike and domeſtic inſtruments. Similar burying places have been diſcovered at Skael on the Mainland, and at Rowſholm in Stronſay. At Skael is likewiſe a curious cauſeway about a quarter of a mile long, compoſed of reddiſh ſtones impreſſed with a variety of figures. The veſtiges of many ancient buildings can be traced in different parts of the iſlands; and ſome ſtructures of leſs antiquity are ſtill tolerably entire. Among the latter may be mentioned the cathedral of St. Magnus, the biſhop's palace and the king's caſtle at Kirkwall. The firſt is kept in good repair, but the two laſt are extremely ruinous. In the iſland of Weir are the remains of the caſtle of Coppirow, or Cubbirow, built by Kobbem Stavanga, a man of great note in the twelfth century. This edifice forms a ſquare of fifteen feet on each ſide; and is ſurrounded by ditches and ramparts, which, with the ſtrength of its walls, evinces it to have been a fortification of no ſmall importance. Of the numerous other buildings characteriſed by ancient writers as lofty and magnificent piles, few retain traces ſufficient to mark decidedly the ſcite on which they ſtood. The biſhop's palace in Eagleſhay, the houſe of Siguid of Weſtneſs, that of Sween in Gairſay, the caſtle of Damſay, the reſidence of Thorkil in Sandwich, the palace of the earls in Orphir, and the celebrated palaces of the princes and biſhops in Birſa, are now completely demoliſhed. Theſe laſt ſtood on a fine lawn near the preſent church, and cloſe to the ſhore, oppoſite to what is called the burgh of Birſa, ſuppoſed to have been formerly a rock fortification, as ſome remnants of a wall are yet viſible on the land ſide. Here are numerous ruins of popiſh chapels, which continue to be much viſited by the common people, from motives of religious veneration. On the iſland of Rouſay is a high ridge or mound, which has received the name of the camp of Jupiter Fring. As it is plainly, however, a natural elevation, and bears no marks of human art either on it or around it, Dr. Barry is of opinion that its preſent appellation has originated with ſome whimſical genius in later times, probably on account of this ſpot being a favourite haunt of the eagle; the bird ſacred to the king of gods and men. Such other veſtiges of antiquity as ſeem worthy of notice, will be mentioned under the name of the iſland to which they may reſpectively belong. Hiſtory of the Orkney Iſlands by the Rev. Dr. Barry, 2d edition by the Rev. James Headrick, 4to. Lond. 1808. The preſent marchioneſs of Stafford has publiſhed a folio volume, with ſeveral etchings executed by her own hand, illuſtrative of the ſcenery, antiquities, &c. of the Orkneys; only 150 copies of this curious, and certainly intereſting volume, were printed, and thoſe for preſentation; when the copper-plates were deſtroyed. Fauna Orcadenſis, or the Natural Hiſtory of the Orkney and Shetland Iſlands, 4to. 1813, by the Rev. Geo. Low.

ORLAMUNDY, a town of Saxony, in the principality of Altenburg, at the conflux of the Orla and the Saal; 40 miles W.S.W. of Altenburg. N. lat. 50° 45′. E. long. 11° 25′.

ORLAND, a town of America, in Hancock county, and ſtate of Maine, ſituated on the eaſt bank of Penobſcot river, at its mouth, having Buckſtown on the north, Penobſcot on the ſouth, and Ellſworth on the eaſt; 17 miles N. of Caſtine.

ORLANDIN, Nicholas, in *Biography*, a learned Italian Jeſuit, was born at Florence in the year 1554. He entered the ſociety at the age of eighteen, and diſtinguiſhed himſelf by his proficiency in literature, particularly in the knowledge of the Latin tongue. Having finiſhed his ſtudies, he filled the poſt of Latin tutor in different houſes belonging to his order, till the ſtate of his health obliged him to relinquiſh that employment, when he was made rector of the college at Nola, and afterwards preſident of the ſeminary for novices at Naples. In the year 1598 he was ſent for to Rome, where he undertook the taſk of drawing up a grand hiſtory of the Jeſuits; but died in the year 1606, when he had completed only the firſt volume of the projected work. It was publiſhed at Rome in 1615, under the title of "Hiſtoriæ Societatis Jeſu Pars prima, ſive Ignatius." This work was continued by father Francis Sacchini, who at different periods publiſhed four volumes; and was at length brought down to the year 1616 by father Jouvency, who publiſhed a ſixth volume at Rome in 1710. Orlandin was the author of "Annuæ Litteræ Societatis Jeſu," for the years 1583, 1584, and 1586; and alſo of "Vita Petri Fabri Soc. Jeſ.," &c. Moreri.

ORLANDO di Lasso, a native of Mons, in Hainault, born 1520. Orlando not only ſpent many years of his life in Italy, but had his muſical education there; having been carried thither ſurreptitiouſly, when a child, on account of his fine voice. The hiſtorian Thuanus, who has given Orlando a place among the illuſtrious men of his time, tells us, that it was a common practice for young ſingers to be forced away from their parents, and detained in the ſervice of princes; and that Orlando was carried to Milan, Naples, and Sicily, by Ferdinand Gonzago. Afterwards, when he was grown up, and probably had loſt his voice, he went to Rome, where he taught muſic during two years; at the expiration of which, he travelled through different parts of Italy and France with Julius Ceſar Brancatius, and at length, returning to Flanders, reſided many years at Antwerp, till being invited by the duke of Bavaria to Munich, he ſettled at that court, and married. He had afterwards an invitation, accompanied with the promiſe of great emoluments, from Charles IX. king of France, to take upon him the office of maſter and director of his band; an honour which he accepted, but was ſtopped on the road to Paris, by the news of that monarch's death. After this event he returned to Munich, whither he was recalled by William, the ſon and

ſucceſſor

ſucceſſor of his patron Albert, to the ſame office which he had held under his father. Orlando continued at this court till his death, in the year 1593, at upwards of 70 years of age. His reputation was ſo great, that it was ſaid of him, "Hic ille Orlandus Laſſum, qui recreat orbem."

As he lived to a conſiderable age, and never ſeems to have checked the fertility of his genius by indolence, his compoſitions exceed in number even thoſe of Paleſtrina. There is a complete catalogue of them in Draudius, amounting to upwards of fifty different works, conſiſting of maſſes, magnificats, paſſiones, motets, and pſalms; with Latin, Italian, German, and French ſongs, printed in Italy, Germany, France, and the Netherlands.

He was certainly one of the moſt fertile and able muſicians whom Europe had then known, ſince the invention of counterpoint. Among the great number of his works, the "Magnum Opus Orlando di Laſſo complectens omnes Cantiones quas Motetas vulgò vocant tam antea editas, quàm hactenus nondum publicatas, a 2 ad 12 Voc., Monachii, 1604," 7 vols. in folio, is much eſteemed. But in France, his popularity chiefly aroſe from the great number of ſongs by Ronſard and Clement Marot, which he ſet to muſic, and which were printed by Adrian le Roy, from 1576 to 1584. His compoſitions were in high favour in England, during the reign of queen Elizabeth.

Two of Orlando di Laſſo's ſons, Ferdinand and Rodolph, were able muſicians, and both in the ſervice of Maximilian, duke of Bavaria; the eldeſt as chapel-maſter, and the other as organiſt to that prince. They were theſe muſicians who collected their father's works, in 7 vols. folio, and publiſhed them in a very ſplendid and ſumptuous manner, dedicating them to their patron, the ſovereign of Bavaria. The general reception, however, of theſe compoſitions ſeems not to have equalled the expectations of the editors: other productions had taken poſſeſſion of the public ear and favour. It is, we fear, in vain to hope for the revival of old muſic; too many are intereſted in the ſucceſs of the new; and ſuch are the viciſſitudes of what are called taſte and expreſſion in this art, that if ſufficient probity and zeal could be found in faſhionable performers, to incline them to attempt doing juſtice to the productions of former times, it is hardly poſſible for them to ſucceed; the accent, energy, and expreſſion are either loſt in the execution, or unintelligible to the hearers. There is, indeed, as little chance for a muſician of the preſent age to perform ſuch productions in the manner of the times in which they were compoſed, as to pronounce a foreign language as well as his own; and if, againſt all calculation, he ſhould ſucceed, this muſic will ſtill be an unknown tongue to the public.

We ſaw, in 1772, Orlando's tomb in the Recollet's church-yard at Munich. On it are carved his own figure, with thoſe of his wife, three ſons, and eight daughters, kneeling by him; date 1595, with a long Latin epitaph.

ORLAY, Bernard Van, was born at Bruſſels about the year 1490. He went to Rome to ſtudy painting, when very young, and had the good fortune to become a diſciple of Raphael Sanzio.

Upon his return to Brabant, he was appointed principal painter to the governeſs of the Netherlands, and was employed for ſeveral years by the emperor Charles V., being conſidered as one of the beſt painters of his time.

The prince of Naſſau engaged him to paint ſixteen cartoons, as models for tapeſtries, which were intended for the decorations of his palace at Breda. Each cartoon conſiſted of only two figures, a knight and a lady on horſeback, repreſenting ſome of the Naſſau family. They were thought worthy of a ſcholar of Raphael, and were afterwards copied by Jordaens in oil. He died in 1560, aged 70.

Orlay, Richard Van, was born at Bruſſels in 1652, the ſon of Peter Van Orlay, an indifferent landſcape painter, from whom, of courſe, Richard firſt received the rudiments of his art.

He furniſhed the world with a prodigious number of works, and is one of thoſe who have contributed to puzzle the connoiſſeurs, by having at different periods choſen different maſters as his models, and made compoſitions in their peculiar taſtes of ſtyle. Altano, Pietro da Cortona, and frequently Nicolo Pouſſin, ſuffer in reputation, by having Van Orlay's labours attributed to them, which are nevertheleſs ingenious enough to give their author a decent place in the ſcale of artiſts. He died in 1732, aged 80.

ORLE, Orlet, or *Orlo*, in *Architecture*, a fillet under the ovolo, or quarter-round of a capital.

The word is French, formed from the Latin *orletum*, or *orlum*, of *ora*, a *border* or *liſt*.

When it is at the top or bottom of the ſhaft, it is called the *cincture*.

Palladio alſo uſes orlo for the plinth of the baſes of columns and pedeſtals.

Orle, in *Heraldry*, is an ordinary in form of a fillet, drawn round the ſhield, near the edge or extremity thereof, leaving the field vacant in the middle. Or it is an inner border (ſee Border), of the ſame ſhape as the eſcutcheon, which doth not touch the extremities of the ſhield, the field being ſeen within and round it on both ſides; ſo that it appears like an eſcutcheon voided.

Its breadth is but half that of the bordure, which contains a fifth part of the ſhield; the orle only a tenth; add, that the orle is its own breadth diſtant from the edge of the ſhield; whereas the bordure comes to the edge itſelf.

There is ſometimes one orle, ſometimes there are two, and ſometimes three. When there are three, or more, they take up the whole ſhield. It is ſometimes borne flory, or counter-flory, or like the *treſſure*; which ſee.

The form of the orle is the ſame with that of the ſhield; whence it reſembles an ineſcutcheon; as repreſented in the *Plate* of *Heraldry*.

The edges of the orle may be ingrailed, indented, inverted, &c. When any bearings, as martlets, trefoils, &c. are placed round an eſcutcheon, on a field, they are termed, or ſaid to be, *in orle*. Some writers mention the number of martlets: but in this, ſays Edmondſon, they expreſs themſelves erroneouſly; becauſe martlets, trefoils, &c. when placed *in orle*, are always eight in number.

ORLEANA, in the *Materia Medica*, the name of the arnotto, or roucou.

ORLEANOIS, in *Geography*, a province of France, before the revolution, bounded on the north by Normandy and Iſle de France, on the eaſt by Iſle de France, on the ſouth by Nivernois, Berri, and Touraine, on the weſt by Maine and Perche; lying between 47° 15′ and 48° 40′ N. lat., and between 0° 35′ and 3° 30′ E. long.; being 33 leagues from north to ſouth, and 42 from weſt to eaſt. This government included Orleanois proper, Sologne, Blaiſois, Beauce, Dunois, Vendomois, the greateſt part of Gatinais, and Perche Gouet. It derived its name from Orleans, its capital. The foreſt of Orleanois, north of the capital, is 15 leagues long, and from two to five broad. This province, together with the Blaiſois and Chartrain, is now divided into the three departments of Loire and Cher, the Loiret, and the Eure and Loire.

ORLEANS, Peter Joseph de, in *Biography*, was born at Bourges in 1641, of an ancient family, in the pro-

vince of Berry. He entered into the ſociety of Jeſuits in 1659, became a very popular preacher, but was particularly famous for his hiſtorical compoſitions, in which he aſſiduouſly employed himſelf till his death, which happened at Paris, in the year 1698. His principal work, and that by which he is moſt known, is his "Hiſtoire des Revolutions d'Angleterre," in three volumes. "But Engliſh hiſtory," ſays the writer in the General Biography, "is a ſubject on which it is impoſſible for a Jeſuit to write with a proper ſpirit; and that of father d'Orleans may be judged of, from his calling Magna Charta 'the rock on which the royal authority is ſplit, and the ſource of all the contentions which have ſince agitated England,' while at the ſame time he avoids giving a view of the contents. From the reign of Henry VIII., if his narrative improves in intereſt and vivacity, it is ſtill more diſtorted by the prejudices of his order." The next conſiderable work of this author is entitled "Hiſtoire des Revolutions d'Eſpagne." The titles of ſeveral other of his works are given in the General Biog.

Orleans, Lewis, *Duc de*, firſt prince of the blood in France, was ſon of Philip, duke of Orleans, afterwards regent of the kingdom, and born at Verſailles in the year 1703. At the early age of ſixteen he was introduced into the council of the regency, made governor of Dauphiné, and nominated grand maſter of the order of our Lady of Mount Carmel and St. Lazarus. In 1724 he married a princeſs of Baden, with whom he lived very happily about two years, when he had the misfortune to loſe her by a premature death. This event led him to renounce the world, and to devote himſelf wholly to devotional exerciſes, and the ſtudy of religion and the ſciences. In the year 1730 he took an apartment in the abbey of St. Genevieve, in which he at length became a conſtant reſident. He expended his immenſe income in the moſt laudable acts of beneficence, and at the ſame time applied himſelf with great diligence and ſucceſs to his literary and ſcientific ſtudies, making himſelf maſter of the Hebrew, Chaldee, Syriac, and Greek languages. He alſo became well acquainted with the writings of the ableſt divines, eccleſiaſtical hiſtorians, and fathers. He was likewiſe extremely well verſed in general hiſtory, geography, botany, chemiſtry, natural hiſtory, natural philoſophy, and the art of painting. He fell a ſacrifice to the intenſeneſs of his ſtudy, and to the ſeverity of the diſcipline to which he ſubjected himſelf, and died in 1752, when he was in the 59th year of his age. He left behind him a vaſt number of theological works, ſome of which poſſeſſed great merit. They, and a very valuable library, were bequeathed by him to the Dominican order. His ſon Lewis Philip, duke of Orleans, died in 1785, at the age of 60. Moreri.

Orleans, Philip Louis Joseph, *Duke of*, was born at St. Cloud in 1747, and became exceedingly notorious in the late revolution. In his youth, his title was that of duke of Chartres. He was brought up to the ſea-ſervice; and in 1778 we find him on board the fleet, commanded by count d'Orvilliers: but we have no account of his having diſtinguiſhed himſelf at that, or any other time. It has indeed been recorded, to his diſgrace, that, in the action with Keppel, he went down into the hold, and refuſed to appear on deck till the engagement was over. This fact, if true, would be ſufficient to put a ſtamp on his character for every thing that was bad: cowardice, in a military officer, is reckoned, of all others, the fouleſt ſtain that can attach to it. After this, however, he was raiſed to a ſtill higher rank in the navy, but without having any opportunity of redeeming his credit, or of adding to his diſgrace. Upon his return, he became extremely diſſipated; and anxious to ſignalize himſelf, where he probably expected little danger, he joined the popular party againſt the meaſures of the court. He violently oppoſed the regiſtering the edicts of the king, as an infringement of the rights of parliament; and entered his written proteſt againſt it. The parliament confirmed the proteſt; and on the next day the duke was ordered to retire to his country-ſeat, at the diſtance of 15 leagues from Paris, and to receive no company there, excepting his own family. He was regarded as the victim to the power of the court. As firſt prince of the blood, his ſituation allowed of no increaſe of dignity; his immenſe revenue was thought to exceed that of any other ſubject in Europe: therefore, as far as honour or wealth was concerned, he could not expect any augmentation, by a change in the government; his conduct was accordingly regarded by the maſs of the people as purely patriotic, and he obtained the title of "Prince of the patriots." He was not contented with this, but was deſirous of going before the public; and accordingly, at a later period, he aſſumed the title of citizen Egalitè. He was elected preſident of the national aſſembly in 1789, but he declined the honour intended him. About this time, the people were ſuffering moſt grievouſly by a ſcarcity, almoſt approaching to a famine; and he liberally expended his immenſe income in relieving, as far as he was able, thoſe neceſſities which he could not avert: hence he became not only obnoxious to the champions of arbitrary power, but was looked upon with extreme jealouſy by thoſe who hoped to riſe by the favour of the multitude, and who, having little or no fortune with which to purchaſe their voices, found themſelves eclipſed by his ſuperior rank and influence. Theſe inſinuated that the name and popularity of the duke might be applied to purpoſes the moſt dangerous; and the duke, who it was thought had given no inſignificant proof of his forbearance, by declining the proffered honour of preſident of the national aſſembly, now eſtabliſhed his character for moderation, by yielding to the wiſhes of his ſovereign, and accepting a commiſſion to the court of St. James, he withdrew himſelf from the eyes of his partial countrymen. This was towards the cloſe of the year 1789; but in the beginning of the following year, rumours were propagated, and reports induſtriouſly circulated, the moſt injurious to the reputation of the duke of Orleans. But that prince, by his ſudden and unexpected return, confounded the malice of his enemies, and ſet at defiance charges that would probably have never been made in his preſence, and which, as they were unſupported by circumſtances, were treated by the national aſſembly as frivolous, and unworthy of any credit. Notwithſtanding this acquittal, he was ſuſpected by thoſe who were neither deficient in penetration nor candour, of having very ambitious deſigns, and of ſecretly attempting the dethronement and deſtruction of the royal family. This became more apparent, from his conduct on the trial of the king. In the courſe of that tranſaction, nothing created greater ſurpriſe and horror than that the ſelf-created l'Egalitè ſhould vote, not only for the death of his ſovereign and very near relation, but againſt allowing him any appeal to the people. It was ſaid in his juſtification, that he intended to have abſtained from giving his vote, but that he was terrified into the act by the threats of the ferocious Robeſpierre. When, on the firſt queſtion of guilty, or not guilty, he pronounced the affirmative, a general murmur pervaded the convention: his vote againſt the appeal to the people was received with equal indications of ſurpriſe; and his opinion on the third queſtion of life or death was awaited with curioſity and impatience. From the tribune he deliberately pronounced theſe words: "Influenced by no conſideration but that of performing my duty; convinced that all who have conſpired,

or who ſhall hereafter conſpire, againſt the ſovereignty of the people deſerve death; I VOTE FOR DEATH." The aſſembly, though not remarkable for its compaſſion, when the king or his family was concerned, was in a general ferment: one member, ſtarting from his ſeat, and ſtriking his hands together, exclaimed, "Ah, le ſcelerat!" and many joined in the expreſſion, and added, "Oh, l'horreur! Oh, le monſtre!" This was in January 1793; and before the cloſe of the year, he was doomed to a like fate. On the 2d of November he was brought to Paris, and on the 6th he was convicted and executed, unpitied by perſons of all parties. In his way to the ſcaffold, he was overwhelmed with all the abuſe and indignities that a rancorous and cruel populace could deviſe; but on that occaſion, aware that he did not merit the perſecution of the people, from whom it came, and on whom he had liberally expended his property, he called forth a degree of dignity and courage that was unexpected, and ſubmitted to the blow with decent fortitude. Adolphus's Hiſtory of France, 1803. Hiſt. of Revolution, by Rabaut de St. Etienne.

ORLEANS, in *Geography*, a city of France, and principal place of a diſtrict, as well as capital of the department of the Loiret. It is divided into three parts, containing 36,165 inhabitants; and its three cantons contain 45,630 inhabitants, on a territory of 12½ kiliometres, in one commune. It was formerly called Aurelıana Civitas, Cenabum or Genabum, and being the capital of the province of Orleanois, was a biſhop's ſee, the reſidence of the Merovingian line, and the ſeat of five councils. The city is large and indifferently built; it contains a cathedral of excellent Gothic architecture with a handſome ſpire, 22 pariſh churches, an old univerſity, and a literary ſociety. The city is pleaſantly ſituated at the foot of a declivity bathed by the Loire; 24 leagues S S.W. of Paris. Without including ſeveral ſuburbs, the city is 2396 toiſes in circuit, formerly environed by a wall and ditch. The mall is an agreeable walk, 2890 feet in length: and here is a fine ſtone bridge of 16 arches over the Loire. Orleans has ſome traffic in corn, wine, and brandy; its manufactures are cloth, ſtockings, refining of ſugar, &c. North of it is an extenſive foreſt, and the country from hence to Paris is flat and unintereſting. This city was taken by Julius Cæſar; in 451 it was beſieged by Attila, king of the Huns, who was defeated by Theodoret, king of the Goths, aſſiſted by Ætius, the general of Valentinian, and the king of the Franks. It was taken by the Normans twice, *viz.* in 855 and 865. The ſiege of the Engliſh in the year 1429, was raiſed by the conduct of Jean de Arc, commonly called the Maid of Orleans. N. lat. 47° 54'. E. long. 1° 59'.

ORLEANS, a county of America, being the middle of the three northern counties of Vermont; a part of the lake Memphremagog projects into the northern part of it from Canada. It contains 27 townſhips: the land is high, and ſends its waters almoſt in every direction. Clyde, Barton, and Black rivers empty into lake Memphremagog; the waters of many branches of Miſſiſcoui, Le Moelle, and Onion rivers, riſing here, fall into lake Champlain; thoſe of Mulhegan and Paſanopſie diſcharge themſelves into Connecticut river. This county contains 1439 inhabitants. —Alſo, a poſt-town of Barnſtaple county, Maſſachuſetts, taken from the ſoutherly part of Eaſtham, and incorporated in 1797; 91 miles from Boſton. Clams are found here in abundance, and conſtitute a profitable article of traffic. One thouſand barrels, of the value of ſix dollars a barrel, are in ſome years ſalted here. The number of houſes in 1800 amounted to 141, and the whole population conſiſted of 174 families, and 1095 perſons.

ORLEANS, *Iſle of*, an iſland of Canada, ſituated in the river St. Lawrence, at a ſmall diſtance below Quebec, remarkable for the richneſs of its ſoil. The S.W. end of the iſland is called Point Orleans. The coaſt is rocky for a mile and a half within the S. channel, where is a careening place for merchants' ſhips. Round Point Levi, and along the S.E. ſide of the river, the ſhore is rocky, but the middle of the baſon is entirely free.

ORLEANS, *New*, the capital of Louiſiana, in North America, ſituated on the E. bank of the Miſſiſippi, 95 miles from the mouth of the river. N. lat. 30° 2'. W. long. 89° 53'. The town is regularly laid out, the ſtreets running at right angles, but they are very narrow, and unpaved. This town ſuffered much by fire in 1788, being reduced from 1100 to 200 houſes in three hours; but it has been ſince rebuilt, principally of brick, and not as before of timber, with flated roofs. Thoſe that are conſtructed of brick conſiſt of two ſtories, without cellars; and the old wooden houſes are of one ſtory, raiſed from the ground for the accommodation of cellars. Some few houſes have piazzas. The public buildings are, a handſome Catholic church, a government houſe, a calabozo or priſon, which alſo ſerves as a court-houſe, a convent, barracks for the ſoldiers, king's hoſpital, a lunatic hoſpital, and a ſmall market-houſe. The ſide next the river is open, and ſecured from its inundations by a raiſed bank, which extends to a diſtance of more than 50 miles. To the N.E. of the town are large marſhes, which contribute to render it unwholeſome in ſummer and autumn, particularly to ſtrangers; whereas the conſtant inhabitants are never afflicted by the epidemic diſeaſes which prevail among foreigners, but are ſaid to be as long-lived as the inhabitants of the northern parts of the United States. Lake Ponchartrain communicates with the town by means of the creek St. John, which proceeds from the lakes through a courſe of ſix miles, and within two miles of the town. But a bar at the entrance of this creek prevents veſſels that draw more than three or four feet of water from entering; but ſmall craft are numerous, and paſſing from Mobile, Penſacola, and the adjacent country, bring their tar, lime, &c. to market by means of this communication. A canal was formed in 1792 from the creek to the town; and at the mouth of the creek where it enters the lake is a ſmall fort of ſix guns. In the year 1802 the principal aggregate exports of American and Spaniſh produce have been eſtimated at

	Dollars.
30,000 bales of cotton, value -	2,000,000
8,000 hogſheads of ſugar, do. -	480,000
90,000 hogſheads of flour, do. -	400,000
Total	2,880,000

In the ſame year were exported, of former crops, about 300,000 lbs. of indigo, value 300,000 dollars. Conſiderable quantities of deer-ſkins and ſome furs are alſo exported; alſo tobacco, ſalt beef and pork, hams, laid, &c. from the Illinois and Ohio rivers. The inhabitants of New Orleans were eſtimated in 1802 to be 10 or 11,000. Its ſituation, not far from the ſea, on a noble river, in a very fertile country, under a ſalubrious climate, and near Mexico, but ſtill nearer to the French, Spaniſh, and Britiſh Weſt India iſlands; with the moral certainty of its becoming a general receptacle for the produce of the extenſive and valuable country on the Miſſiſippi, Ohio, and its other branches, afford advantages which ſeem to enſure the growing proſperity of this city, more eſpecially as it is now in the poſſeſſion of the United States. Morſe.

ORLENGA, a town of Ruſſia, in the government of Irkutſk, or the Lena. N. lat. 56°. E. long. 105° 40′.

ORLEY, a town of Pruſſia, in Oberland; 16 miles N.N.E. of Soldau.

ORLIAC, a town of Croatia; 20 miles S. of Carlſtadt.

ORLOI, a town of Lithuania; 60 miles E. of Pinſk.

ORLOP, in *Ship Building*, a tier of beams below the lower deck of large ſhips, the intervals of which are framed with earlings, and laid with oak board along the midſhips of the ſhip, chiefly for the convenience of ſtowing away the cables. There is alſo a *platform* in the midſhips of ſmaller ſhips, called the *orlop*, and for the ſame purpoſe.

ORLOV, in *Geography*, a town of Ruſſia, in the government of Viatka, on the Viatka. N. lat. 58° 20′. E. long. 49° 44′.—Alſo, an iſland in the Caſpian ſea. N. lat. 45° 50′. E. long. 53° 14′.—Alſo, a river of Ruſſia, which runs into the Tchernaia, N. lat. 65° 20′. E. long. 168° 14′.

ORLOVKA, a river of Ruſſia, which runs into the Irtiſch, N. lat. 53° 50′. E. long. 75° 24′.—Alſo, a river of Ruſſia, in the government of Archangel, which runs into the Frozen ocean; 28 miles N. of Ponoi.

ORLOVOGORODITSCHE, a town of Ruſſia, on the river Iſchim; 120 miles S.E. of Tobolſk. N. lat. 56° 32′. E. long. 70° 44′.

ORLOVSKOE, a government of Ruſſia, bounded on the N. by the governments of Smolenſk and Kaluga, on the W. by Smolenſk and Novgorod Sieverſkoi, on the S.W. by Novgorod Sieverſkoi, on the S.E. by Kurſkoi and Voroneztſkoi, and on the E. by Tambovſkoe and Tulſkoe: its length from E. to W. is 208 miles, its breadth variable from 20 to 100. N. lat. 50° to 54°. E. long. 33° 14′ to 39°.

ORLUCE, a town of Poland, in the palatinate of Sandomirz; 8 miles N.W. of Kreminiek.

ORLY, a town of Lithuania, in the palatinate of Brzeſk; 44 miles E. of Pinſk.

ORME, Robert, in *Biography*, the ſon of Dr. Alexander Orme, a phyſician and ſurgeon in the ſervice of the Eaſt India Company, was born at Anjengo, in the Travancore country, in 1728. He was ſent to England for his education, and was entered at Harrow-ſchool when he was only ſix years of age. After he left ſchool, he was placed for a year in the office of the accomptant-general of the African Company, in order that he might be initiated in commercial tranſactions, and then he embarked for Calcutta, where he arrived in 1742. At firſt he was not in the Company's ſervice, but when once engaged for them, he acquired the higheſt reputation for the zeal with which he entered into their intereſts. At the ſame time he made the deepeſt reſearches into the inſtitutions, manners, and cuſtoms of the natives of India, ſo that, in the year 1752, when ſome regulations were thought neceſſary in the police of Calcutta, he was deſired to give his opinion on the ſubject. He accordingly drew up the greater part of "A General Idea of the Government and People of Indoſtan." In 1753 he returned to England, and was frequently conſulted by men in power on Indian affairs, and reſpecting plans, at that time in agitation, for ſupporting the Britiſh intereſt in Hindooſtan. Mr. Orme reviſited India in 1754, having already been appointed by the court of directors a member of the council at Fort St. George. He ſeconded, by his able and ſpirited advice, thoſe meaſures which annihilated the French power in that country, and gave to the Engliſh that decided aſcendancy which they have ever ſince poſſeſſed. Mr. Orme held the office of commiſſary and accomptant-general during the years 1757-8, but in the latter year his health obliged him to embark for England. He was taken priſoner on his return, and carried to Mauritius, from whence he was embarked for the Cape of Good Hope. He arrived in England in the autumn of 1760, and ſettling in London, began to collect a choice library, and to employ himſelf in preparing a work on the Military Tranſactions in India. The firſt volume was publiſhed in 1763, entitled "The Hiſtory of the Military Tranſactions of the Britiſh Nation in Indoſtan from the Year 1745." This volume brought down the hiſtory to the year 1756. An hiſtorical diſſertation on the Mahomeddan conqueſts and eſtabliſhments in that country, compriſing a view of the peculiar character and cuſtoms of the Hindoos, was prefixed. It was extremely well received by the public. The Eaſt India Company, duly ſenſible of his merits, and of the importance of his hiſtorical reſearches, not only gave him free acceſs to all their records, but appointed him to be their hiſtoriographer, with a ſalary of 400*l. per annum*. To obtain the moſt accurate information reſpecting the war which was to be the ſubject of the ſecond volume, he went over to France in 1773, where he was furniſhed liberally with various authentic documents. It was not till 1778 that the work was brought to its completion. The ſecond volume was now publiſhed, which contained all the events which took place in the Engliſh ſettlements in India from 1756 to 1763, with an inveſtigation of the riſe and progreſs of the Engliſh commerce in Bengal, and an account of the Mahommedan government from its eſtabliſhment in 1200. In 1782 Mr. Orme publiſhed a work, entitled "Hiſtorical Fragments of the Mogul Empire of the Marattoes, and of the Engliſh Concerns in Indoſtan from the Year 1659." This, which was an octavo volume, was his laſt publication, for though his literary purſuits were unremitted, yet his health was unequal to the exertions required for the compoſition. In 1792 he left the metropolis, to enjoy in retirement the ſociety of his friends, and the recreation afforded by a well aſſorted library. In January 1802 he died in the ſeventy-third year of his age. "The intellectual character of Mr. Orme," ſays his biographer, "was chiefly marked by good ſenſe, ſagacity, and judgment. To theſe qualities were added an active curioſity, and a cultivated taſte, which fitted him both for the collection and for the lucid arrangement and happy diſplay of hiſtory. He poſſeſſed a refined taſte for muſic, the arts of deſign, and poetry, and among his literary compoſitions are ſome elegant copies of verſes."

After his death his "Hiſtorical Fragments" were reprinted in a quarto volume, with the addition of a paper on the "Origin of the Engliſh Eſtabliſhment, and of the Company's Trade at Broach and Surat;" and another, containing "A General Idea of the Government and People of Indoſtan." To this volume is prefixed an account of the life and writings of the author, to which our readers are referred for farther information.

Orme, L', in *Geography*, a town of France, in the department of the Nievre, and chief place of a canton, in the diſtrict of Clamecy. The place contains 2416, and the canton 12,788 inhabitants, on a territory of 375 kiliometres, in 10 communes.

Orme's *Head, Great*, a cape on the N. coaſt of Wales, in the county of Carnarvon. N. lat. 53° 24′. W. long. 2° 5′.—Alſo, *Little Orme's Head*, a cape on the ſame coaſt, five miles S.E. of the former.

ORMEA, a town of France, in the department of the Stura, on the Tanaro; 10 miles S. of Ceva.

ORMILLOS, Los, a town of South America, in the province of Tucuman; 36 miles N. of St. Salvador de Jugui.

ORMO, a ſmall iſland in the Baltic, between the coaſt of

of Finland, and the iſland of Aland. N. lat. 60° 27′. E. long. 20° 43′.

ORMOND, the name of two extenſive baronies in the county of Tipperary, Ireland, diſtinguiſhed by the terms Upper and Lower. From them the illuſtrious family of Butler took the titles of earl and duke of Ormond.

ORMOSIA, in *Botany*, a genus founded by the late Mr. George Jackſon, F.L.S. and named by him from ορμος, *a necklace*, or *ſtring of beads*, becauſe the beautiful ſeeds, parti-coloured of ſcarlet and black, are worn, by ladies, in the Weſt Indies, as well as in Europe; being uſually intermixed with thoſe of *Abrus precatorius*, with which they agree in colours, though they greatly exceed the *Abrus* in ſize. Jackſon Tr. of Linn. Soc. v. 10. 358. Brown in Ait. Hort Kew. ed. 2. v. 3. 3. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, ſhort, bell-ſhaped, gibbous at the baſe, two-lipped; upper lip two-lobed; lower in three deep ſegments. *Cor.* papilionaceous, of five petals, with linear claws; ſtandard roundiſh, emarginate, erect, ſcarcely longer than the wings, convex; wings two, oblique, obtuſe, ſomewhat heart-ſhaped at the baſe; keel of two obtuſe hatchet-ſhaped petals, the length of the wings. *Stam.* Filaments ten, ſeparate, awl-ſhaped, the length of the corolla, concealed in the keel; anthers roundiſh, of two cells. *Piſt.* Germen ſuperior, ovate-oblong; ſtyle the ſize and ſhape of the filaments, incurved; ſtigmas two, obtuſe, approximated, one above the other. *Peric.* Legume woody, compreſſed, of two valves and one cell. *Seeds* one or more, orbicular, compreſſed, large, coloured.

Eſſ. Ch. Calyx five-cleft, two-lipped. Corolla papilionaceous. Stigmas two, approximated, obtuſe; one of them lateral. Legume woody, compreſſed. Seeds one to three.

1. O. *coccinea*. Scarlet Necklace-tree. Jackſ. Tr. of Linn. Soc. v. 10. 360. t. 25. (Robinia coccinea; Aubl. Guian. v. 2. 773, excluding Plumier's ſynonym.)—Leaves pinnate; leaflets coriaceous, ovate, revolute, naked on both ſides. Legume ſmooth and ſhining.—Native of Guiana; not yet introduced alive into Europe. A *tree*, with zigzag branches, clothed with ruſty down. *Leaves* a foot long or more, compoſed of from four to ſix pair of ſtalked leaflets, each near three inches in length, elliptical or ovate, and entire, furniſhed with a ſtrong midrib, and many fine tranſverſe veins. *Stipulas* in pairs, diſtinct from the footſtalk. *Flowers* in a large, terminal, racemoſe panicle, purpliſh. *Legume* ſhort, very hard and ſhining. *Seeds* moſtly ſolitary, rarely two, ſhining, ſcarlet with a large black ſpot.

2. O. *daſycarpa*. Ruſty-podded Necklace-tree. Jackſ. n. 2. t. 26. Ait. n. 1. (Sophora monoſperma; Swartz Ind. Occ. 722. Willd. Sp. Pl. v. 2. 501.)—Leaves pinnate; leaflets numerous, pointed, flat, ſmooth on both ſides. Legume downy.—Native of Jamaica and other parts of the Weſt Indies; brought by Capt. Bligh, in 1793, to Kew, where it flowers in the ſtove in June and July. Much like the former, but differing in the above characters. The *legume* is often orbicular, with one ſeed only; ſometimes oblong, with two or three.

3. O. *coarctata*. Cloſe-flowered Necklace-tree. Jackſ. n. 3. t. 27.—Leaves pinnate; leaflets unequal; naked above; ruſty and hairy beneath.—Gathered by Mr. Alexander Anderſon in Guiana. The *leaves* are ſmaller than in the laſt; their leaflets gradually larger as they recede from the branch. *Panicle* denſe and ſhort, though of many flowers. *Germen* hairy. *Seeds* like the laſt, but ſmaller.

ORMSKIRK, in *Geography*, a market town in the hundred of Weſt-Derby, and county palatine of Lancaſter, England, is ſituated at the diſtance of 40 miles S. by W. from Lancaſter, and 209½ miles N.W. by N. from London. It conſiſts chiefly of four principal ſtreets, which interſect each other nearly at right angles. The property of this town anciently belonged to Burſcough priory, in the neighbourhood. Edward I. conferred on it the privilege of a market and fair, and this grant was renewed and confirmed by his ſucceſſor, with additional immunities. Ormſkirk at preſent is a conſiderable manufacturing place; a large quantity of cotton, and thread for making ſail-cloth, being ſpun here, both by the hand and by means of machinery. Here are held the petty ſeſſions for the Ormſkirk diviſion of the hundred. The market day is Saturday weekly, and there are two fairs during the year. The church, an ancient ſtructure, with a tower at one end, poſſeſſes the remarkable feature of having a ſpire entirely detached from it. The reaſon of this ſtrange circumſtance remains unknown; but as it is an anomaly in our ſacred architecture, it ſeems not unlikely to have been merely the reſult of whim, to which ſource indeed it is aſcribed by tradition. The interior of this church contains ſeveral monuments in honour of the Stanlies, earls of Derby.

According to the parliamentary returns of 1811, Ormſkirk compriſes 678 houſes, and 3064 inhabitants, which is an increaſe, ſince 1801, of 64 houſes, and 510 perſons.

Two miles north from the town ſtand the remains of Burſcough priory. This houſe was founded in the time of Richard I. by Robert Fitzhenry, lord of Lathom, who beſtowed upon the monks conſiderable property, emoluments, and alms. Lathom-houſe, ſituated in its vicinity, is noted for the vigorous defence which Charlotte, counteſs of Derby, made againſt the parliamentary forces diſpatched to beſiege it in the reign of Charles I. After loſing about two thouſand men, the republican commanders were compelled to raiſe the ſiege, by the approach of prince Rupert, without having been able to bring the heroic counteſs to ſubmiſſion either by force or perſuaſion. The preſent houſe is the ſeat of E. Wilbraham Bootle, eſq. M.P. Beauties of England and Wales, vol. iv., by John Britton, F.S.A.

ORMUS, or HORMUZ, an iſland of Aſia, at the entrance of the Perſian gulf, about 10 miles in circumference; diſtant about five miles from the continent of Perſia, and ſomewhat more than 25 from that of Arabia, formerly much celebrated, but now retaining little or nothing of its ancient ſplendour. It has lately belonged to Mulla Ali Shah, a Perſian, who made himſelf maſter of it immediately after the death of Nadir Shah, whoſe admiral he had been. This prince of Ormus poſſeſſes likewiſe a part of the iſle of Kiſheme, the other part being ſubject to the prince of Seer. This ſmall iſland is traverſed by a high mountain from E. to W., and is believed to be anciently a volcano; it is full of rocks, barren and deſtitute of all neceſſaries, except ſalt, of which there is ſuch plenty, and that ſo hard, that it is ſaid to be uſed in building houſes. The ſoil is compoſed of a white ſand, formerly imported into Europe. It has no water but that which is preſerved, after rain, in ciſterns; ſo that, in its moſt flouriſhing times, when it was the emporium of this part of the world, its inhabitants had not only their victuals, but alſo the water they uſed from the continent. The air in ſummer was ſo exceſſively ſultry, that people were forced to live in grots. Its commodious ſituation, however, rendered it formerly the moſt famous mart in the Eaſt. Ships repaired hither from all parts of the Indies, from the coaſts of Africa, Egypt, and Arabia, and a regular trade was carried on by caravans acroſs the country. Hence its ſovereigns, who poſſeſſed ſome ſmall territory upon the continent of Perſia, became rich and powerful; and at proper ſeaſons of the year, merchants reſorted to it from

from all countries, and particularly the Venetians, who carried on a great trade in jewels tranſported from hence to Baſſora, and by caravans to Aleppo, or to Suez by ſea, then overland, by the Nile, to Alexandria, where they were delivered to the merchants to whom they were conſigned. Its commercial accommodations and celebrity drew the attention of the Portugueſe, who made themſelves maſters of the town and citadel. The former ſtood upon the ſea-coaſt, and conſiſted of about 3000 houſes; and the inhabitants, conſiſting of Arabians, Mahometans, Indians, and Jews, were eſtimated at 40,000. The fortreſs built on a point of land was regular, beautiful, and ſtrong; and at length furniſhed with 300 pieces of cannon. Caravans paſſed twice a year, *viz.* in April and September, from Aleppo to Baſſora, and thence were tranſported to the iſle of Ormus. Theſe caravans conſiſted of 5 or 6000 perſons, and brought with them articles of immenſe value. At the ſame time, private ſhips navigated the ſea from Malacca, and the caravans that traverſed Perſia, brought vaſt quantities of rich and valuable commodities. The city and caſtle of Ormus were in ancient times deemed the pride and glory of the Eaſt, the magnificence of which was expreſſed after the oriental manner, in this phraſe, "that the world being round as a ring, Ormus might be conſidered as its jewel." By the wealth which flowed into and from it, in the manner already related, it became the richeſt and moſt buſy, not to add the moſt delightful place in the world. This city was founded at the beginning of the 14th century; and the famous Perſian monarch, Shah Abbas, with the aſſiſtance of the Engliſh, deſtroyed it in 1622, hoping thus to transfer its trade to Gambroon or Bander-Abaſſi, *i. e.* the port of Abbas; the moiety of the cuſtoms of which port he granted the Engliſh for their good ſervice. Gambroon, however, is far from being what Ormus was. When Ormus was loſt by the Portugueſe, it was computed, that excluſively of jewels and rich merchandiſe, the plunder and ready money amounted to more than two millions. The Portugueſe afterwards made an attempt for the recovery of Ormus, but were diſappointed in conſequence of failure of ſuccour and ſupport from the viceroy of Goa; and the place remained in a ruined ſtate. N. lat. 27° 8′. E. long. 56° 40′.

ORNAMENTS, in *Architecture*, expreſs all the ſculpture, or carved work, with which a piece of architecture is enriched.

Ornaments *in Relievo*, are thoſe carved on the contours of mouldings: as leaves, ſhells, ſcrolls, flowers, &c. See Relievo.

Ornaments *in Creux*, are thoſe cut within the mouldings; as eggs, flutes, &c. See Creux.

Vitruvius and Vignola alſo uſe the word ornament to ſignify the entablature.

Ornaments, *Diſtribution of*. See Distribution.

ORNANO, in *Geography*, a town of the iſland of Corſica, and chief place of a canton, in the diſtrict of Ajaccio; the canton contains 4478 inhabitants.

ORNANS, a town of France, in the department of the Doubs, and chief place of a canton, in the diſtrict of Beſançon; nine miles S.S.E. of it. The place contains 3500, and the canton 13,838 inhabitants, on a territory of 272½ kiliometres, in 28 communes. N. lat. 47° 6′. E. long. 6° 13′.

ORNE, one of the nine departments of the N.W. region of France; compoſed of the ſouth part of Normandy, and almoſt the whole of Perche, is bounded on the N. by the department of the Calvados, on the N.E. by the department of the Eure, on the E. by the department of the Eure and Loire, on the S. by the departments of the Sarte and the Mayenne, and on the W. by the department of the Channel, in N. lat. 48° 10′; 32 French leagues in length, and 15 in breadth; containing 6375 kiliometres, or 310 ſquare leagues, and 397,931 inhabitants. It is divided into four diſtricts, or circles, 35 cantons, and 627 communes. The circles are Domfront, including 110,526, Argentan, 106,495, Alençon, 67,372, and Montagne, 113,538 inhabitants. According to Haſſenfratz, the circles are ſix, the cantons 51, and the number of inhabitants 348,972. The contributions in the 11th year of the new era amounted to 3,666,903 fr. and the expences to 535,186 fr. 33 cents. The capital is Alençon.

This department is traverſed from E. to W. by a ridge of hills partially covered with foreſts, and contains many tracts of an indifferent ſoil, yielding grain, flax, hemp, and paſtures. Here are iron mines and mineral ſprings.

ORNES, a town of France, in the department of the Meuſe; ſix miles N.N.E. of Nerdun.
